A long and winding valley, the entrance to which is an opening in the mountains behind the Setheum, leads to two other valleys, that of the Tombs of the Kings, and the Western Valley. Both of these contain royal sepulchres, but those of the former are more important than those of the latter, as far as is known, for this may contain unopened tombs. The sepulchres in the Valley of the Tombs of the Kings are twenty or twenty-one in number. Nineteen are sculptured, and are the mausolea of kings, of a queen with her consort, and of a prince, all of the Eighteenth, Nineteenth, and Twentieth Dynasties, unless we make Rameses I. the earliest of these sovereigns to have been head of the Nineteenth Dynasty, instead of including him among the rulers of the Eighteenth. One tomb is without sculpture, and there is likewise an unsculptured passage running for a considerable distance into the mountain which may perhaps be regarded as the commencement of a tomb never completed, making the twenty-first. Their plan is always the same in its main particulars, but they differ greatly in extent, in consequence of having been commenced at a king's accession, or even before (since one of them is the tomb of an heir-apparent), and continued throughout his reign, like the pyramids of Memphis. Their paintings and painted sculptures likewise do not present remarkable varieties, since they are almost wholly of a religious character, and principally refer to the future state. They are remarkable for the manner in which they illustrate the Egyptian religion, and the beauty of their execution; but their mysterious and intricate nature forbids any detailed description of them in the present article. The plan of one of the most interesting sepulchres may however be described. The tomb of Sethee I., commonly called Belzoni's, since that explorer first opened it since ancient times, is in the freshest state of preservation, except in its outer part, although the miserable barbarism of modern travellers is yearly lessening its beauty. We enter by a staircase, and pass along a steep passage, which terminates in a deep pit, now filled up. Thus far the subjects and inscriptions which occupy the walls, are unfinished, showing that the tomb was not completed. Immediately beyond the pit the part discovered by Belzoni commences with a hall 26 feet by 27, supported by four square pillars, the walls of which are covered with very beautiful painted sculptures, including the celebrated procession of the four races. To the right of this is another chamber, supported by two columns, the sculptures of which were never commenced, having only been drawn in outline. From the left side of the former chamber we descend a flight of steps, which leads to a passage, another flight of steps, and then another passage ending in a chamber 17 feet by 14, from which we pass into a hall 27 feet square, having six square pillars, and on either side a small chamber. This forms the portico of the great sepulchral hall, the most splendid part of the tomb, which is of an oblong form, 19 feet in length and 30 in breadth, with an arched roof. In the midst, in a depression, was a splendid sarcophagus of alabaster, and on its removal blocks of stone were found filling up the entrance of an inclined descent which was cleared for 300 feet by Belzoni, without its termination being discovered. It is not improbable that the king was buried in a chamber at the end of this passage. The great sepulchral hall is covered with beautiful painted sculptures, and on its ceiling are astronomical or astrological representations, resembling the astronomical ceiling of the Rameseum of El-Kurneh. A door in the left side of the sepulchral hall leads to a chamber which has two square pillars, and on the same side is a cell; there is another chamber on the opposite side. A large apartment, which was left unfinished, is behind that in which was the sarcophagus, and is the last of those contained in the tomb, if the inclined

[1] *Horæ Æg.*, pp. 68, 69.

[2] *Modern Egypt and Thebes*, vol. ii., p. 222.

Egypt.

descent does not lead to other unknown ones. From the entrance to the end of this chamber is a distance of about 300 feet.

The tomb of Rameses III. is among the most splendid of the royal sepulchres. Its length a little exceeds 400 feet, but from the nature of the rock its sculptures are less delicately executed than those of the tomb of Sethee I. In cells on either side of its passage, a little within the entrance, are interesting paintings illustrating manners and customs, in one of which is the celebrated representation of the harpers.

The tombs which have been found in the Western Valley are only four in number, and but two of these contain paintings. The latter are of Amenoph III. and of King Skhai or Skhee, a sovereign who appears to have come to the throne in the year B.C. 1475 or 1474, though some suppose him to have been of the sun-worshippers who succeeded Amenoph III. The former is decorated with paintings in a very good style, but unfortunately they have sustained much damage; the latter is historically interesting as a record of an uncertain king, but its paintings are of poor execution. Nowhere perhaps are we so forcibly struck by the feeling of the ancient Egyptians with respect to death and the future state, as in the Valley of the Tombs of the Kings, and in the sepulchres themselves. The desolateness of the spot, apart from all signs and sounds of life, fitted it for the solemn use to which it was assigned, and those long dark passages, and lofty chambers, on whose walls we see the awful punishments of the wicked, and the rewards of the good, show us the most secret mysteries of the Egyptian religion in a manner suited to their greatness. The Pharaohs, whose valour and whose piety we have seen commemorated on the walls of their stately temples, are worthily entombed in these marvellous sepulchres; and here we take our farewell of them and of Thebes, knowing well that the world has since produced no monuments excelling those of "the City of Thrones."

Arment (Hermonthis).

Not far south of Thebes, on the western bank, is the large village of Arment, the old Hermonthis, where stands a picturesque temple built by Cleopatra. It has two courts, having colonnades, and three chambers around which was also a colonnade, of which but one column now stands. It is of small dimensions, having been the Typhonium attached to the great temple of Munt, the divinity of the place, which has been razed. On the other bank of the river, a little higher, at Tód, anciently Tuphium, is a small Ptolemaic temple. Not far beyond, and about 20 miles above Thebes, by the course of the stream, are the "Gebeleyn" or "Two Mountains," on the western side of the river, where the sandstone begins. The town of Isnè, the ancient Sne, called by the Greeks Latopolis, is likewise situate on the western bank, about twelve miles higher, and is remarkable as containing a very fine Egyptian monument, the portico of its great temple of Kneph. This is in the heart of the modern town, and until lately was much choked with rubbish. Mohammad 'Alee having, however, caused it to be cleared, its beautiful proportions can be appreciated. It is supported by twenty-four lofty and massive columns, six in front, and four deep, having capitals of various forms, of which those alone in corresponding positions on opposite sides are of the same description, a deviation from regularity of which we do not see examples previous to the Greek rule. The columns and walls are covered with minute sculptures of the bad style of the period when the portico was erected, that of the Cæsars. It contains the hieroglyphic names of Claudius, Vespasian, Titus, and other emperors as late as Severus. The back is, however, more ancient, since it bears the name of Ptolemy Epiphanes, being the front of the older temple of which nothing more is known for certain to remain. Upon the ceiling is a Zodiac, from which this monument was supposed to have been of very great antiquity before the interpretation of hieroglyphics had been discovered. On the other bank of the Nile, on the site of Contra Latopolis, is a small temple of the Ptolemaic and Roman periods.

Isnè (Latopolis).

Eilethyas.

A few miles above Isnè, where both the Libyan and Arabian chains approach the river, are the curious remains of Eilethyas. There is a small temple of the Ptolemaic time, and two little sacred edifices of the period of the Pharaohs, but the most interesting monuments are the tombs and the fort. The former, which are excavated in a hill, are very remarkable as illustrating history, husbandry, &c.; and in one of them is the very curious inscription of its occupant Aahmes, chief of the mariners, recording his services to early kings of the Eighteenth Dynasty.[1] The fort is a large enclosure of crude brick,[2] which was a place of importance as early as the Shepherd war, for it is mentioned as the "Fort of Seben," that is of Eilethyas, in a part of the inscription above mentioned, which relates to the time of that war. The goddess of the place was Seben, or Lucina (Eilethyia), who was especially regarded as the protector of Upper Egypt.

Adfoo (Apollinopolis Magna).

Having proceeded about twelve miles to the southward we reach the large village of Adfoo, which represents the town called by the Greeks Apollinopolis Magna, the great temple of which yet stands in a comparatively perfect state, and is one of the most stately monuments of ancient Egypt, although of a time at which art had greatly declined. It was dedicated to Har-het, the god of the place, whom the Greeks called Agathodæmon. Unfortunately mounds of rubbish within and around it, as well as the huts of the village, some of which stand, or stood until recently, on its roof, injure the effect, and prevent a complete examination of the temple.

The great propylon which forms the front of the temple measures about 226 feet in width, and is, like the rest of the edifice, in a good state of preservation. The sculptures upon its front represent acts of worship by Ptolemy the Elder, son of Auletes, who is pourtrayed slaying prisoners. The portal between the wings of this propylon is the entrance to the temple, of which the first part is a great court about 161 feet long and 140 broad, with a colonnade along its front and each side, of columns with various capitals fronting covered galleries. At the end is a portico having 18 columns, 6 in front and 3 deep, about 82 feet broad and 46 long measured within, beyond which are a hall and passages and other chambers, the most important of which is an isolated sanctuary. This part of the temple, commencing with the portico, is much choked with rubbish, which often reaches to the roof. The wall of the great court is continued so as to inclose the further portion of the temple, leaving a passage around it. The sculptures show that it was probably commenced by Ptolemy Philopator and completed at the end of the Greek monarchy, though an insignificant additional subject was added by Claudius. Not far from the great temple is a smaller one of the sort called Typhonia, containing two chambers, around which runs a gallery supported by Typhonian columns.

Gebel-es-Silsileh.

About 23 miles above Adfoo the mountains on either side, which had for some distance confined the valley to a narrow space, reach the river and contract its course. They are low but steep and picturesque, and in their western side are seen the entrances of excavations. They receive the appellation of Gebel-es-Silsileh, a name derived from the earlier Silsilis. The most interesting of the excavations is a rock-temple in which is pourtrayed the defeat of a negro nation by King Har-em-heb, or Oros, of the Eighteenth Dynasty: here, also, are subjects depicting acts of worship paid to Nilus and Sebak. To the southward of this, and

Egypt.

also facing the river, are the entrances of several excavated tombs, the representations in which are not of a remarkable character. Beyond these are three chapels of the time of the Nineteenth Dynasty. On the opposite side are very important quarries where much of the materials of the great temples was cut, especially under the Eighteenth and subsequent Dynasties.

Beyond Gebel-es-Silsileh, although the mountains recede, the tract of cultivated land is extremely narrow, and sometimes the desert touches the river: this is partly owing to the sinking of the level of the stream, which, as mentioned in an earlier part of this article, was very anciently restrained by some barrier at Silsilis. About eleven miles above that place is the extremely picturesque temple of Ombos, placed on a rocky eminence called "Kóm-Umboo," or "the Hill of Umboo." It stands within a great enclosure of crude brick walls, which we see on every side, except that towards the river. There is a portal in this wall of the time of Queen Amen-numt and Thothmes III. The great temple is double, one-half having been dedicated to the worship of Sebak, and the other to that of Har-oër or Aroëris. It consists of a portico of fifteen columns, whereof two have fallen, the foremost of which were connected by a wall of intercolumniation having two entrances, behind which is a smaller portico and remains of chambers, including the two sanctuaries. The earliest name here is that of Ptolemy Philometor,[1] unless Champollion be right in saying that the name of Epiphanes is also found in the temple,[2] which appears to have been completed by Ptolemy Auletes. There were also remains here of a smaller Ptolemaic temple which have been washed away by the river.

Kóm-Umboo (Ombos).

Nothing remarkable occurs between Ombos and Syene, a distance of about twenty miles. The valley is confined to a very narrow space by the mountains, which take bold forms on both sides near the latter place. Just before we reach it, we see the Island of Elephantine, where is the famous Nilometer of the Roman time. The town of Aswân, which represents the ancient Syene, stands amid palm-trees on the eastern bank opposite to Elephantine. It is a considerable place, of greater political than commercial importance, and has succeeded to an older town of the same name, the ruins of which occupy the river's bank, and a granite hill to the south. Among them may be mentioned a pier, which has a well which is most probably the Nilometer constructed by 'Amr, the Muslim conqueror of Egypt. In the ruined town is also a small temple of Roman date. Farther to the south is its extensive Arab cemetery, which is full of curious tombstones bearing inscriptions in Cufic characters. In the granite hills to the eastward are the quarries whence were taken so many of the obelisks and statues which adorned the Egyptian temples.

Aswân (Syene).

The bed of the river above Aswân is obstructed by numerous rocks and islands of granite, one of the latter of which, that of Saheyl, is interesting on account of the numerous hieroglyphic tablets and inscriptions at its southern part. This island is almost a mile and a half above Aswân, and at the distance of another mile from it begin the rapids called the First Cataract, caused by the granite rocks, which almost entirely choke the river. The Cataract is so inconsiderable, that during the inundation, boats favoured by a strong northerly wind can pass it without aid, though at other times it is necessary to hire natives, who drag them through, but then the principal rapid has a fall of only five or six feet,[3] and that is not perpendicular. Nevertheless the roaring of the troubled stream, and the red granite islands and rocks which stud its surface, through which our boat threads its way, give the approach a wild picturesqueness until we reach the open stream, less than two miles farther, and the beautiful isle of Philæ suddenly rises before the eyes, completely realizing our highest idea of a sacred place of ancient Egypt.

The First Cataract.

Philæ is beyond the proper limits of Egypt, but as it is usual to describe it in noticing Aswân and the rapids, some account of it will here be given, which is the more desirable as it contains very beautiful and interesting monuments, and was held in high reverence by the ancient Egyptians as a burial-place of Osiris. It is very small, being only a quarter of a mile long, and about 500 feet broad. On its granite rock is a little alluvial soil and some vegetation, with a few date-palms, but its verdure has been exaggerated, and its beauties are little owing to it. On the east side is a small but very picturesque temple, now hypæthral, of the Greek and Roman time, and unfinished. It is 48 feet in width and 63 in length, and has 14 columns with capitals of various forms, connected by intercolumnal walls. The great temple of Isis stands to the westward of this. Its front is formed by a propylon, before which is a kind of court, to be afterwards described. The portal bears the name of Nectanebes I., but the wings were added by the Ptolemies, making the entire width about 122 feet. Through the portal we enter a court, on the right side of which is a gallery fronted by columns, behind which are several small chambers, and on the left side is a separate small temple of Athor, the main entrance to which is by a door and passage in the left wing of the great propylon. This small temple commences with a portico having four columns with the faces of Athor sculptured in high relief upon each of its sides above the capital. Beyond this are three chambers behind one another, above the door of the first of which is a Greek dedication by Ptolemy Physcon, or Euergetes II., and the two Cleopatras. The temple was, however, commenced by Epiphanes. The court of the great temple, or that of Isis, is bounded by a second propylon of smaller dimensions than the first, and forming the entrance to the portico, which is a very elegant structure raised on ten columns, eight of which are at the back and one on each side. It is partly hypæthral, an open space being left between the two columns last mentioned. The beautiful forms of the columns, and the bright remains of colour on them and the walls, with the effect of the sunlight through the aperture of the roof, produce a most graceful and pleasing effect. Behind this hall are several small apartments, one of which, reached by a staircase, contains very curious sculptures relating to the story of Osiris. The temple appears to have been commenced by Ptolemy Philadelphus (whose name is the earliest found there), and was continued under the Roman emperors. The court before the temple remains to be noticed. It is bounded by two galleries with columns in front. One of these is about 250 feet long, and is built close to the western side of the isle terminating at a small temple of Athor near its southern end. This edifice, which is much ruined, was supported by columns with the block adorned with faces of Athor above their capitals, of which six stand; it was raised by Nectanebes I. The eastern gallery, which is shorter than the other, is not parallel with it, and thus shows that this court was not part of the great temple, but rather an approach to it. The other remains are of minor importance, and the same may be said of the ruins of a temple on the neighbouring large island of Bigè.

Philæ.

A few words must be said respecting the eastern and western deserts. The latter desert is remarkable for two valleys besides those called the Oases. The first of these valleys is that of the Natron Lakes to the westward of the Delta, containing four Coptic monasteries, the remains of the famous anchorite settlement of Nitria. To the southward of this, and parallel to it, is a sterile valley called the Bahr bela-Ma, or "River without Water." Yet farther to the southward is the Little Oasis (Oasis Parva), about 100

Western desert.

Egypt.

miles from the Nile in E. Long. 29°., nearly due west of the town of Bahnesè. It contains remains of little interest. Within 200 miles due south of this oasis is another, of which the usual appellation is Wáh ed-Dákhileh, where, near the town of El-Kasr, is an Egyptian temple of the Roman period. This, according to Sir Gardner Wilkinson,[1] is the most flourishing of the oases. About half-way between this oasis and the Nile at Thebes lies the Great Oasis (Oasis Magna). Here, near the town called El-Khárigeh is a considerable temple of the Persian and subsequent times; and in the same oasis are other ruins of the period of the Ptolemies and Cæsars. The Oasis of Jupiter Ammon, that of Seewah, is not far from the coast at a great distance to the westward, and it is not properly included in Egypt. Various Arab tribes occupy this desert besides the settled inhabitants of the oases.

Eastern desert.

In the eastern desert must be mentioned the town of Es-Suweys, or Suez, anciently Arsinoë, a small place at the head of the gulf to which it gives its name. To the southward, a little below lat. 29°, are the secluded Coptic convents of St Antony and St Paul near the sea. Farther south are the porphyry quarries of Gebel-ed-Dukhán, extensively worked under the Romans, and the granite quarries of Gebel-el-Fateereh. Considerably more to the south, at El-Hammámát, on the old way from Coptos to Philoteras Portus are the Breccia Verde quarries, which were much worked from very early times, and have interesting hieroglyphic inscriptions. At Gebel Zabárah are emerald mines now abandoned as unproductive. At the various mines, and on the routes to them and to the Red Sea, are some small temples and stations, ranging from the Pharaonic to the Roman time. Along the shore of the sea are the sites of several ancient ports, the most important of which were Myos Hormos and Berenice, and the modern town of El-Kuseyr. The northern part of this desert is occupied by the Ma'ázee Arabs and smaller tribes as far as the Kuseyr road, beyond which are the 'Abábdeh, an African tribe very different from the Arabs in appearance, and to the south of these, to the east of Lower Nubia, is the Bisháree tribe, a people also of African race.

SECTION IV.

STATISTICS.

Government.

Egypt is governed by a Páshá of the family of the late Mohammad 'Alee, in virtue of the firmán of the 13th of February 1841, by which the government of that province of the Turkish empire was conferred on him, and on his then living family, the members of which were to succeed him by seniority; by that firmán the governor of Egypt was to recognise all laws and treaties enacted and concluded by the Porte; the imposts and revenues of Egypt were to be collected in the name of the Sultán, one-fourth of the revenue was to be transmitted yearly to Constantinople, the army, limited to 18,000 men, the officers above the rank of major to be appointed by the Sultán on the nomination of the Páshá, and ships-of-war to be built only by express permission of the Porte. The non-fulfilment of any of these conditions would cancel the concessions then granted.

Under the Páshá the several departments of the administration are presided over by ministers and councils. These offices were mostly created by Mohammad 'Alee, and are great improvements on the former system of government, although necessarily filled by creatures of the higher power. The principal offices are that of the minister for the internal administration of the affairs of the state, that for foreign affairs, and those for war, marine, finance, and public instruction, a tribunal of commerce, and councils of health in Cairo and Alexandria. The provinces into which Egypt is divided are governed by officers called Mudeers, and the subdivisions of those districts by Mámoors and Názirs. The Mudeers are Turks, but native Egyptians were appointed by Mohammad 'Alee, and since by his successors, to the inferior posts. The government *employés*, as clerks, &c., are chiefly Copt scribes.

Army.

By the firmán of investiture, the army was reduced to 18,000 men, but since the war with Russia it has been very much increased, and, as is well known, the Egyptian contingent not only forms a large portion of 'Omar Páshá's army, but has very honourably distinguished itself. When on the peace-footing it is variously distributed throughout Egypt, but the artillery is confined to Cairo and Alexandria, and a considerable garrison of regular infantry is always maintained in both those cities. Each Mudeer has under his orders a corps of irregulars, and about five regiments of regular cavalry are generally stationed in Upper Egypt. According to reliable information obtained in 1849, the following is the scale of pay per month:—private soldier, 15 piasters; corporal, 20; sergeant, 25; sergeant-major, 30; lieutenant, 300; captain, 500; major, 2000; lieutenant-colonel, 2750; colonel, 4000. The privates receive rations and clothing, and the officers, rations. The commissioned officers of the cavalry and artillery receive rather more, viz. lieutenant, 360 piasters; captain, 600; colonel, 5000. A soldier in the irregular cavalry (who finds his own horse) receives 112½ piasters, and in the irregular infantry 65, in either case everything included. The pay of the Egyptian army is, therefore, good; but the common soldiers generally receive orders on the treasury, in lieu of money, which are not presentable for some months, and are not always honoured when due. The regular troops are recruited by impressment, every village being required to furnish its quota, but the irregulars are volunteers—Turks and Albanians. In the last war the Páshá also maintained a force of Arab horsemen. A regiment of regular infantry is composed of four battalions of 1000 men each, divided into eight companies, of which one is a grenadier and another a light company, and four guns are attached to each regiment. A regiment of regular cavalry consists of six squadrons, each of 192 men, a battery of horse artillery, of six companies, and one of foot artillery, of eighteen companies. The irregulars (horse and foot) are divided into corps of 400 men, each commanded by a "chief of four hundred."[2]

Navy.

Since the conclusion of the Syrian war, until the present struggle, the navy has been totally inactive. At the former period it numbered 11 ships of the line, 6 frigates (one moved by steam-power), 5 corvettes, 9 brigs (3 being steamers), and 2 cutters. Some of these were constructed in the naval yard at Alexandria, but the larger number were contracted for in Europe. Great care was bestowed on the formation of the navy, and the establishments connected with it at Alexandria, but the Egyptians do not seem to be a maritime people, or, at any rate, their men-of-war have none of the tautness and neatness of European ships of the class.

Colleges and schools.

Mohammad 'Alee devoted considerable attention to the establishment of colleges and military schools, besides sending young men to Europe for purposes of scientific study. In Cairo and its environs he founded several elementary schools[3] of a higher order than the native schools of the same class (mentioned in Section I. of this article), a school of languages, now at Boolák, a printing-press at Boolák, which, however, has been principally used for the publica-

[1] This account of the deserts is chiefly taken from Sir Gardner Wilkinson's *Modern Egypt and Thebes*, vol. i., p. 382, *et seqq.*; and ii., p. 353, *et seqq.*

[2] Private information. See Mengin, *Histoire*, vol. iii., p. 135; and for details respecting the Navy, *Ib.*, p. 143.

[3] Government Schools are of three classes or grades, and in all number about fifty in the whole country.

Egypt.

tion of works on military and naval sciences, &c., though some valuable books (among these the *Thousand and One Nights*) have issued from it at the expense of private individuals; and a school of medicine at the Kasr-El-'Eynee, between Cairo and Masr El-'Ateekah. At El-Khankah and in its neighbourhood, he placed a military hospital and a school of medicine, a veterinary college, an infantry school, and a school of music; at El-Geezeh, a cavalry school; and as Turà, one of artillery. A civil hospital likewise exists in Cairo, and another at Alexandria.[1] The dock-yard and arsenal of Alexandria, with the gun-factory at the village of El-Hód el-Marsood, organized by French officers, are very creditably conducted. Indeed all these establishments are remarkably well designed and carried out, when we consider the lamentable deficiency of similar institutions in the East, and the bad organization of the few that exist there.

Manufactories.

Mohammad 'Alee also promoted manufactures, and established large manufactories of cotton, silk, and woollen goods, tarbooshes, &c., and, especially in Upper Egypt, sugar-refineries. Ibráheem Páshá was much opposed to his father's policy, and in pursuance of his own views he laid out extensive plantations of olive and other trees, erected powerful steam-engines for the irrigation of his lands, and on all his estates endeavoured to encourage agriculture. It cannot be doubted that had he lived the correctness of his conviction that Egypt is an agricultural, and not a manufacturing country, would under his rule have been fully verified.

Culture of cotton.

Mohammad 'Alee introduced cotton, and largely cultivated it; the Turkish grandees found that from it they were able to extract more gain than from other field-produce, and large tracts were speedily devoted to its culture. The necessity, however, of excluding the waters of the Nile has caused several destructive inundations, and the cotton, being a monopoly of the Páshá has not tended to enrich the producer.[2]

Agriculture.

It may truly be said that the agriculture of the country is in the hands of the government, unless Sa'eed Páshá have made very extensive alterations in the system carried out by his father. By the seizure of almost all private lands, by enormous government monopolies, and by heavy taxation on all the fruit of their labour, Mohammad 'Alee effectually destroyed every feeling in the Felláh beyond the mere desire for daily bread; and the cruelty and oppression of subordinate officers rendered his condition more wretched than these exactions alone would have done. The agriculturists are compelled to sell their produce to the Páshá at his own price, and he again sells it to the consumers, and for export, at an arbitrary tariff, by which he secures an exorbitant profit. This rule applies *always* to some kinds of produce (as cotton, flax, &c.), and very often to all, although such is not invariably the case.

Taxation, &c.

The principal taxes are direct taxes on land, which, with indirect exactions from the Felláhs, amount to nearly one-half of the entire revenue of Egypt, the poll-tax, a species of income-tax (firdeh) of about one-twelfth of a man's annual income, with a maximum of 500 piasters; the tax on palm-trees, water-wheels, &c. To these sources of revenue must be added the profits obtained by the sale of produce, custom-dues at the sea-ports, and a duty paid by the inhabitants of Cairo and other large towns on all kinds of grain, with other custom-dues, tax on fisheries and freight.

Revenue.

The total revenue may average about 3,000,000 of pounds sterling.[3] The fullest published table of the revenue and expenditure of Egypt is perhaps that given by Mengin for the year 1833; since that time few great alterations have taken place in the country; but it must be received with caution, as we believe it is derived from government statistics, which in eastern countries are generally distorted for state purposes. It will, however, be found useful as giving the relative amount of various sources of income, and heads of expenditure.

REVENUE FOR 1833.[4]

	Purses.
Land-tax	225,000
Capitation, or poll-tax	70,000
Duty on grain	36,000
Profit on other produce	90,000
Do. on linen	12,000
Do. on silks	9,500
Customs and Octroi duties at	
Alexandria	6,000
Damietta and Boolák	7,353
Old Misr	1,601
Suez and El-Kuseyr	6,000
Deráwee	250
Fisheries of El-Menzeleh	2,750
Duty on salt, boats, and fish	3,500
Do. on merchandise entering from Syria by land	200
Profit on lime, plaster, and stone	4,400
Do. on liquids	2,771
Do. on senna	260
Do. on fisheries and Octroi of the Feiyoom	580
Do. on hides, dressed and undressed	7,000
Octroi of Upper and Lower Egypt	3,200
Tax on dancers, &c.	500
Do. on beasts for slaughter	2,000
Do. on jewellery and lace	450
Do. on inheritances	1,200
Do. on Wekálehs and Bazaars in Upper Egypt	400
Tribute paid by the rayahs	640
Profit on the mint	3,000
Do. on mats	800
Do. on natron and sal-ammoniac	1,000
Do. on soda (Alexandria)	300
Tax on palm-trees	4,000
Freightage of government vessels	2,400
Total	505,055

EXPENDITURE FOR 1833.

Government works	18,000
Tribute to the Porte	12,000
Navy	60,000
Palaces	10,000
Rations of employés	5,000
Irregular cavalry	6,500
Bedawees	5,000
Machinery, &c.	15,000
Boat-yard (Boolák)	3,300
Military schools	1,500
Printing-press	350
Dock-yard (Alexandria)	15,505
Páshá's kitchen	4,000
Matériel of war	14,000
Forage	2,500
Purchase of clothing and jewels, &c.	14,000
Total	399,814

Field-produce.

The principal field-produce for the same year was as follows:

	Ardebbs.		Hundred-weights.
Wheat	1,450,000	Cotton	114,500
Beans	700,000	Sugar	8,558
Barley	650,000	Henneh (hinnè)	35,000
Maize	160,000	Flax	18,000
Millet	750,000	Nitre	15,784
Lentils	70,000		Okes.
Rice	80,000	Indigo	77,300
Linseed	22,000	Opium	14,500
Sesame Seed	18,000	Silk	6,450

Imports and exports.

According to the annual report issued by the Custom-house at Alexandria, the total amount of exports in 1853 was L.3,472,000, and of imports from all parts L.2,670,000. Great Britain, Austria, and France, are the countries principally trading with Egypt, and the exports and imports to and from those countries were:

	Great Britain.	Austria.	France.
Exports.........	L.1,787,546	L.389,000	L.491,000
Imports.........	1,153,000	310,000	242,000

The same report gives the following table of exports:

Wheat (quarters)	706,000	To Great Britain	405,000
Beans „	215,000	...	169,000
Barley „	 62,000	...	50,000
Indian Corn „	 47,000	...	46,000
Linseed „	 20,000	...	18,000
Sesame Seed „	 32,000	...	...
Cotton (bales)	181,000	...	100,000
Flax „	 44,000	...	35,000
Wool „	 22,000	...	11,000
Henneh „	 5,300	...	...

The total value of manufactures imported was L.475,000, of which Great Britain contributed L.353,000; and the number of merchant-ships that sailed in 1853 from the port of Alexandria was 1191, of which 944 were with cargoes, and 247 in ballast. The *imports* are principally timber, woollen caps (tarbooshes), cochineal, copper, and copper wire, coal, cloth, drugs, tin-plates, iron wire, fruit (fresh and dry), oil, paper, jewellery, &c., sugar, cotton, woollen and silk stuffs, glass, &c. From Syria, India, and the East are imported shawls, silks, tobacco, spices, coffee, &c., and from the south, elephant-tusks, hides, castor-oil, senna, colocynth, and slaves; of the latter about 5000 are annually brought from the interior, of which some 1500 are sold in Egypt.

The following shows the amount of the principal exports to Europe for the years 1850–54, both inclusive:

	Bales Cotton.	Do. Flax.	Ardebbs Wheat.	Do. Beans.	Do. Barley.
1850	146,387	29,549	961,171	474,420	180,006
1851	121,439	30,715	1,163,949	465,380	178,782
1852	270,168	26,243	783,004	370,920	131,948
1853	148,829	30,799	815,629	320,239	68,771
1854	150,943	15,269	1,011,695	394,167	114,428

Measures.

The Egyptian measures are: The " fitr" or space measured by the extension of the thumb and first finger; the " shibr" or span; the common cubit = 22⅔ inches, the cubit of about 25 inches, used principally for Indian goods, and the cubit of about 26½ inches, used for European cloth. Of the measures of land, the feddán was equal to about 1 English acre and one-tenth; it is now less than an acre. It is divided into " keeráts" or 24ths, and consists of 333⅓ kasabehs or rods. The kasabeh is 22 " kabdahs," and the kabdah, about 6¼ inches, or the measure of a man's fist with the thumb erect. The Egyptian league varies in Upper and Lower Egypt, and is stated to be, in the former, equal to a journey of an hour and a half, and in the latter, to one hour's journey. The " ardebb" is equal to very nearly 5 bushels, and consists of 6 " weybehs," and each weybeh of 4 " rubas."

Weights.

The weights are the "kamhah" (or grain of wheat), the 64th of a " dirhem," and 4th of a " keerát." It is equal to about ¾ of an English grain. The " habbeh" (or grain of barley) is the 48th of a dirhem and 3rd of a keerát, and = $\frac{127}{128}$ English grain. The keerát, or carat, is the 24th of a " mitkál;" and = from $2\frac{125}{128}$ to 3 English grains. The dirhem = 47⅝ to 48 English grains. The mitkál = weight of a deenár = from $71\frac{7}{16}$ to 72 English grains. The " wukeeyeh" or ounce = from 571½ to 576 English grains. The " ratl" or pound = from 1 lb. 2 oz. 5¾ dwt., to about 1 lb. 2 oz. 8 dwt. troy. The " wukkah" or oke = from 3 lb. 3 oz. 13¾ dwt. to 3 lb. 4 oz. troy. The " kantár" or hundred-weight = from 98 lb., less 200 grs., to about 98 lb. avoirdupois.

Money.

European sovereigns and dollars are current in Egypt; the former being now equivalent to about 100 piasters, the latter, if French, to about 20 piasters, and if Spanish (pillar-dollars), to about 22 piasters; but the value of these coins is constantly changing. The Spanish doubloon, and Venetian sequin are also current, and so are Constantinople coins. Of native coin the " faddah" (or para) is equal to $\frac{6}{25}$ of a farthing, and there are pieces of 5, 10, and 20 faddahs. The " kirsh," or Egyptian piaster, contains 40 faddahs, and is equal to 2⅖ pence. These coins are of silver and copper. Of gold coins there are the " kheyreeyeh" of 4 piasters, and the kheyreeyeh of 9 piasters (but the value of these coins has recently depreciated), and pieces of 5, 10, 20, and 100 piasters. The " riyál beledee," or native dollar, is equal to 90 paras, but is only a nominal money, as is the " kees," or purse, which contains 500 piasters, and the " khazneh," or treasury of 1000 purses. For the weights, measures, and money we are indebted to the *Modern Egyptians*. (R. S. P.)

EHRENBREITSTEIN (*i.e. Broad stone of honour*), a town of Rhenish Prussia, government of Coblentz, on the right bank of the Rhine, immediately opposite Coblentz, with which it is connected by a bridge of boats. Pop. (1849) of town 2198; military, 1783. The town stands at the foot of a rocky precipitous height rising 772 feet above the river, and occupied by the celebrated fortress of Ehrenbreitstein, one of the strongest places in Europe. The fortress was originally a Roman castrum: and during the middle ages it was the stronghold of the electors of Treves, who in later times occupied the palace at the foot of the rock, now used as a granary. The French under Marshal Boufflers, aided by the celebrated Vauban, in vain besieged it in 1688. In 1799, however, it fell into their hands, after a siege of fourteen months, in which the garrison was reduced to such a state of famine, that a pound of horse flesh sold for 30 kreutzers, or somewhat more than 1s. The French blew up the defences when they evacuated it on the peace of Luneville. Since 1814, Prussia has expended large sums in the reconstruction of this fortress. It is defended by about 400 pieces of cannon, and on three sides the escarped rocks and steep slopes would bid defiance to almost any attack. Its weak point is on the N.W., where three successive lines of defences have been constructed. The platform on the top of the rock (serving for a parade-ground) covers vast arched cisterns capable of containing a three years' supply of water for the garrison, furnished from springs without the walls. There is also a well sunk 400 feet deep in the rock, and communicating with the Rhine. The castle of Ehrenbreitstein has been celebrated by Lord Byron, in the following magnificent stanza:—

Here Ehrenbreitstein, with her shattered wall
Black with the miner's blast upon her height,
Yet shows of what she was when shell and ball
Rebounding idly on her strength did light:
A tower of victory! from whence the flight
Of baffled foes was watch'd along the plain;
But Peace destroy'd what War could never blight,
And laid those proud roofs bare to Summer's rain,
On which the iron shower for years had pour'd in vain.
Childe Harold.

EIA, or EY, is the pure Icelandic or Scandinavian for island. Hence the termination *ey* in names of places denotes that they are islands; as Ramsey, the isle of rams; Shepey, the isle of sheep, &c. Eia is also sometimes used for water; and hence the names of places near water sometimes terminate in *ey*.

EICETÆ, a sect of Syrian monks of the seventh century, who used to recite their prayers dancing with the nuns or other females who frequented the monasteries. In this they pleaded the example of Miriam the sister of Moses. They were soon suppressed.

EICHHORN, JOHANN GOTTFRIED, celebrated for his works on biblical criticism, was born in 1752, at Dörrenzimmern, in the principality of Hohenlohe-Oehringen. After having been for some time rector at Ohrduff, he was in 1775 appointed professor of oriental languages at Jena, and in 1788 professor of philosophy at Göttingen, where he died in 1827. His principal works are the Introductions to the Old Testament, 3 vols. 1780–83—to the Apocryphal Books, 4 vols. 1795—and to the New Testament, 1 vol. 1804; Universal Repertory of Biblical Literature, 10 vols. 1787–1810; History of the World, 5 vols. 1799–1814; History of the three last centuries, 6 vols. 1803; History of the Nineteenth Century, 1 vol. 1817; History of Literature, 12 vols. 1805–12; and on the Hebrew Prophets.

EICHSTADT, a town of Bavaria, circle of Middle Franconia, on the Altmühl, 54 miles N.N.W. of Munich. It is the capital of a small principality formerly belonging to the prince-bishops successors of St Willibald, but secularized in 1801, and in 1817 given to Prince Eugene Beauharnois, Duke of Leuchtenberg. It is a neat and well-built town; and is the seat of a bishop and of an appeal court for the circle. The castle formerly occupied by the prince-bishops is now the summer residence of the ducal family, and contains the celebrated Brazilian cabinet and other collections. The cathedral, a Gothic edifice founded in 1259, contains many curious monuments of bishops and canons, the shrine and statue of St Willibald to whom the church is dedicated, and some good paintings. The church of St Walpurgis contains the bones of that saint, in a small recess above the altar, inlaid with gold. From these, at certain times in the year, there flows a stream of oil, to which are attributed certain healing qualities. There are a number of other churches, a capuchin monastery, a nunnery, ecclesiastical seminary, Latin school, public library, and several museums; manufactories of earthenware, hardware, and woollen goods, with breweries and stone quarries. About a mile from the town is Willibaldsburg, a castle standing on a height, and the residence of the bishops till 1725. In the vicinity is a handsome monument, erected by the citizens to Prince Eugene Beauharnois. Pop. 7000.

EIDER, or EYDER, a river of Denmark, having its source in a small lake 8 miles S. of Kiel, flowing generally westward, and falling into the German Ocean at Tönningen, after a course of 90 miles, for 70 of which it is navigable. It forms with the Kieler Canal a navigable connection between the North Sea and the Baltic.

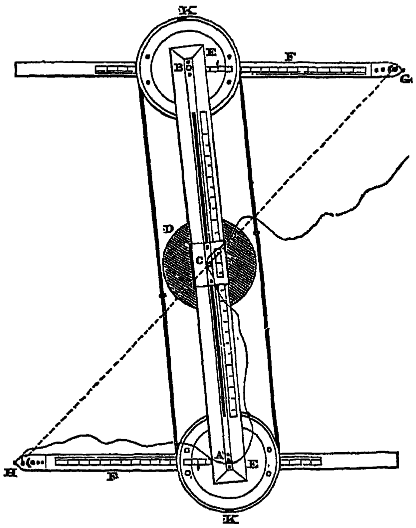
EIDER DUCK. See index to ORNITHOLOGY.

EIDER *Down*, the down of the eider duck. The eider duck plucks off the down from its breast for the purpose of making its nest, which it continues to renew as often as deprived of it, until its breast becomes quite bare.

In commerce this down is sold in balls about the size of a man's fist, and weighing from three to four pounds. It is so remarkably fine and elastic, that if one of these balls be opened and cautiously held near a fire to expand, it will fill a quilt about five feet square. Supplies of it are received chiefly from Norway, Iceland, and the Faroe Islands, where the birds abound. There are two kinds of it, sea-weed down and grass down. The former is the heaviest, but not so easily cleaned as the other.

EIDOGRAPH (εἶδος and γράφω), a very ingenious instrument for copying drawings, either upon a reduced or an enlarged scale, invented in 1821 by Mr Wallace, professor of mathematics in the University of Edinburgh.

The instrument is represented in the annexed figure.



The *beam*, AB, which is made of mahogany, slides backwards and forwards in a *socket*, C; and the socket turns on a vertical axis, supported by the *fulcrum*, D, which stands on a table. There is a slit in the beam, through which the axis of the socket passes, so that, when the beam slides in the socket, a portion of it passes on each side of the axis. There are two equal wheels, E, E, below the beam, which turn on axes that pass through pipes fixed at A, B, near its extremities; and a steel chain passes over the wheels as a band, by which a motion of rotation may be communicated from the one to the other. There

are two *arms*, F, F, which slide in sockets along the lower face of the wheels, just under their centres; at the extremity, G, of one arm, there is a metal *tracer*, with a handle attached to it, by which its point may be carried over the lines in any design; and at H, the extremity of the other arm, there is a black-lead pencil fixed in a metal tube, which is ground to fit exactly into a pipe, so as just to slide up or down. In using the instrument, the pencil, in its tube, is raised by a thread which passes over a pulley, and it descends again by a weight with which it is loaded.

From the perfect equality of the wheels, it is easy to see that, if the arms attached to them be placed parallel in any one position, they will retain their parallelism, although one of the wheels, and consequently both, be turned on their centres. Supposing, now, that BC and AC, the parts into which the axis is divided at the centre, have any proportion whatever to each other, if the distances of the tracing point G, and pencil point H, from the centres of their wheels, have the very same proportion, then it follows, from the elements of geometry, that the tracing point G, the centre C, and the pencil point H, will be in a straight line; and further, that CG and CH, the distance of these points from the centre, will have to each other the constant proportion of CB to CA, or of EG to AH. Such being the geometrical property of the *eidograph*, if the subject to be copied be fixed to the table on which the instrument stands, and the tracing point be carried over every line of the design, the pencil point will trace a copy in all respects similar to the original. To facilitate the adjustment of the instrument, so that the copy may have any given ratio to the original, there are scales of equal parts on the beam and the two arms; by these and verniers, both halves of the beam, and equal lengths on the arms, are each divided into 1000 equal parts, and at certain intervals corresponding numbers are marked on them. By means of the scales, when any ratio is assigned, the adjustment is made without the least difficulty. To avoid any derangement by the chain slipping on the wheels, there are *clamps* at K and K, which hold it fast to the wheels at points where it never quits them. They are slackened when the instrument is adjusted. (See also PANTOGRAPH, and PLATOMETER.)

EIGNE (Norman *aisne*), eldest; an epithet used in law to denote the eldest son.

EILAU-PREUSSISCH, a town of Prussia, province of East Prussia, government of Königsberg, and 22 miles S.S.E. of the town of that name. It is chiefly celebrated for the victory gained there by the French over the united Prussian and Russian armies on 8th February 1807. Pop. (1849) 2778.

EILENBURG, a town in the Prussian province of Saxony, government of Merseburg and circle of Delitzsch, situated on an island in the Mulde, 9 miles N.E. of Leipzig. Pop. (1849) 9754, chiefly engaged in the manufacture of cotton and in calico-printing. It is surrounded by walls, and has an old castle now in ruins. Large quantities of hops are grown in the vicinity.

EIMBECK, or EINBECK, a town of Hanover, capital of the principality of Grubenhagen, in the landrost of Hildesheim on the Ilme, 39 miles S. by E. of Hanover. Pop. about 5700. It is inclosed by old walls and ditches, and is generally ill-built and dirty. Alexander's church contains numerous monuments of the dukes of Grubenhagen. Eimbeck was formerly celebrated for its beer, and it still has some breweries; but the chief manufactures are linen and woollen stuffs, stockings, leather, and chemical products. It has an active trade in flax and agricultural produce.

EINSIEDELN, a market-town of Switzerland, canton of Schwitz, on the Sihl, 9 miles N.N.E. of Schwitz. Pop. about 5000. Above the town, on a naked plain 3000 feet above the level of the sea, stands the famous Benedictine Abbey of Einsiedeln. It was founded in 906, but has been several times rebuilt, the present edifice dating from 1719. The building is in the modern Italian style, but is more remarkable for size than for architectural beauty. It has many spacious apartments, a library of 26,000 volumes, a museum, and a marble chapel with an image of the Virgin. The treasury was plundered by the French in 1798. Numerous pilgrims, not only from Switzerland but also from other countries, annually resort to this abbey, particularly on the 14th September. The annual average is about 150,000; and within a fortnight in 1834 no fewer than 36,000 pilgrims repaired to the shrine. The town contains about 50 or 60 inns, chiefly for the reception of pilgrims. Paracelsus was born here; and Zuinglius was for some time curate of Einsiedeln.

EISENACH, a principality of Germany, forming part of the possessions of the grand duke of Saxe-Weimar-Eisenach. It consists of one principal and several detached portions, the former being bounded on the N. by Prussian Saxony, E. by Saxe-Gotha and Saxe-Meiningen, S. by Bavaria, and W. by Hesse-Cassel. This principality was formerly an independent possession; but on the death of the last duke in 1741, it fell by succession to the dukes of Saxe-Weimar, of whose dominions it now forms a circle. It has an area of 466 square miles, and in 1853 had 82,321 inhabitants. The general character of the soil is mountainous, and the grain produced is not equal to the wants of the inhabitants.

EISENACH, the capital of the above principality, is situated at the confluence of the Hörsel and Nesse, 42 miles W. of Weimar. Pop., including suburbs, about 10,000. The town is surrounded by walls, and is clean and well-built. It has a handsome ducal palace, several churches and hospitals, a town-hall, library, mint, gymnasium, normal school, and school for foresters. The chief manufactures are woollen, linen, and cotton goods, soap, white lead, and leather. About a mile and a half S. of the town is the celebrated castle of Wartburg—once the residence of the landgraves of Thuringia—in which Luther was confined for ten months, after his return from Worms, under the friendly arrest of the Elector of Saxony. The chapel in which he preached, and the cell which he occupied, have been carefully preserved.

EISENBERG, or EISENBURG, a town of Germany, duchy of Saxe-Altenburg, and 20 miles W. of Altenburg. It stands on a height not far from the Saale, is surrounded by walls, and has a castle with an observatory, a town-hall, and hospital. Manufactures—porcelain, ribbons, &c. Pop. 4800.

EISENSTADT, a free royal town of Hungary, county of Oedenburg, on the frontiers of Austria, 26 miles S.E. of Vienna. Pop. 5700. The town consists of three principal streets, and is surrounded by walls with two gates. It contains the splendid palace of the prince of Esterházy, built by Prince Paul Palatine of Hungary, in 1683, but altered and enlarged in 1805. The interior is tastefully fitted up, and the banqueting-hall is capable of accommodating 1000 persons. The park is large, rising in terraces, and ornamented with temples and cascades. It has a large orangery, containing 400 orange trees, and conservatories with about 70,000 species of exotic plants. The Franciscan monastery contains the burial vault of the Esterházy family. On the north of the town are extensive zoological gardens.

EISLEBEN, a town in the Prussian province of Saxony, government of Merseburg, and circle of Mannsfeld, 20 miles W.N.W. of Merseburg. Pop. (1849) 9481. It consists of an old and a new town (the former being surrounded with walls and ditches), besides several suburbs. It has an old castle, and several churches, of which St Andrew's contains the pulpit from which Luther preached; a gymnasium, and two hospitals. In the vicinity are extensive copper and silver mines, which afford employment to a large portion of the inhabitants. Eisleben is celebrated as the birth-place of

Martin Luther. The house in which he was born has been rebuilt, and is now used as a charity school.

EISTEDDFOD (Welsh, from *eistedd*, to *sit*), the name given to the assemblies or sessions of the Welsh bards, at which poets and minstrels contended for prizes after the manner of the ancient Greeks. These meetings were discontinued after the year 1568; but the old custom has been revived of late, and annual meetings for the recitation of prize poems and performances on the harp are now held under this name. (See Pennant's *Tour in Wales*.)

EJECTMENT, in *Law*, a writ or action which lies for the recovery of possession of land from which the owner has been ejected, and for trial of title. Ejectment may also be brought by the lessor against the lessee, for rent in arrears, or for holding over his term; also by the lessee for years who has been ejected before the expiration of his term.

EKATERINEBURG, the chief town of a cognominal circle, in the government of Perm, Asiatic Russia. It is situated on the river Iset, at the foot of the E. declivity of the Ural Mountains. This town was founded by Peter the Great in 1723, and is regularly built and fortified. It is the seat of a mining administration for the district, and has a mint, museum of mineralogy, mining school, extensive foundries and forges, and works for the cutting and polishing of precious stones. Being on the high road from Russia to Siberia, this place enjoys a considerable transit trade. Pop. (1851) 15,852, almost wholly employed in the mines, and in the working of metals.

EKATERINOSLAV, or JEKATERINOSLAV, a government in the south of European Russia, bounded on the N. by the governments of Poltava, Kharkov, and Voronez, E. by the territory of the Don Cossacks, S. by the sea of Azoph and the government of Taurida, and W. by the government of Kherson. The district of Taganrog, and the territory of the Azovian Cossacks belonging to this government, are separated from it by the territory of the Don Cossacks, and extend along the N.E. shores of the sea of Azoph. The area and population are as follows:—

	Area in Sq. Miles.	Pop. in 1846.
Ekaterinoslav	23,734	787,200
Taganrog	1,680	76,900
Azovian Cossacks	116	6,000
	25,530	870,100

The population consists of Russians and Cossacks, with a considerable admixture of German colonists and other races. About two-thirds of the surface consist of an open steppe or plain without trees, and only adapted to pasturage. This is particularly the case with that large portion lying to the E. of the Dnieper; to the W. of that river the soil is much more fertile. The inhabitants are chiefly pastoral, and possess immense numbers of horses, cattle, sheep, hogs, goats, &c. They also devote some attention to bees and silkworms. The grain produced is scarcely sufficient for home consumption. The other productions are hemp, flax, peas, beans, vegetables, and fruits.

EKATERINOSLAV, the capital of the above government, is situated on the right bank of the Dnieper, immediately below the Cataracts, in N. Lat. 48. 27. 20., E. Long. 35. 5. 53. The first stone of the town was laid by the Empress Catherine II. in 1787. It is laid out on a regular plan with broad rectangular streets, but is still far from being completely filled up. Pop. (1851) 12,117. It is the seat of an archbishop, and has an ecclesiastical seminary, gymnasium, and manufactures of woollens and silks.

EKRON, the principal and most northerly of the five Philistine states, was originally assigned to Judah, although afterwards apparently given to Dan. It was the station of the ark when taken by the Philistines. Eusebius and Jerome describe the village as lying between Azotus and Jamnia. It is incidentally noticed in the history of the Crusades under the name Accaron; and has been identified by Robinson with a small Moslem village, five miles south of Ramleh and now called Akri.

ELÆOTHESIUM, the anointing apartment in the ancient gymnasia and baths. See BATHS, and GYMNASIUM.

ELAINE, the name given by Chevreul to the thin oily principle of fats and oils. See CHEMISTRY.

ELAM (ELYMAIS), a country frequently mentioned in Scripture, but not very definitely marked out either by the sacred writers or by the ancient geographers. It was peopled originally by a Semitic tribe descended from Elam, whence its name. In Scripture it is generally connected with Media, and the Elamites are described among the nations of the Persian empire, while Susa is said by Daniel to lie on the river Ulai (Eulæus or Choaspes), in the province of Elam. It thus seems to have formed a part of the ancient Susiana—the modern Khusistan—which was bounded E. by Persia Proper (ancient Persis, modern Fars), W. by Babylonia (the Arabian Irak), N. by Media, and S. by the Persian Gulf. By the classical geographers Elymais is generally distinguished from Susiana. The Elymæi and Kissi formed the ancient population not only of this province, but also of Persia, whence, under Elam, the sacred writers often include the country of the Persians in general. Along with the Uxii, the Kissi, and the Cossæi, who inhabited the neighbouring districts, the Elymæi were renowned for their skill in archery; and from the days of Chedorlaomer, the contemporary of Abraham, they were frequently the terror of the world. The prophecy of Jeremiah (xlix. 30–34), that they would be destroyed by the Chaldæans, received its fulfilment when Nebuchadnezzar subjected Western Asia to his dominions, and his successor Belshazzar established his throne at Susa, the capital of Elam.

ELAPHEBOLIA, in *Grecian Antiquity*, a festival in honour of Diana the huntress. The offering on this occasion was a cake made in the form of a deer (ἔλαφος.) This festival was instituted, it is said, to commemorate a victory obtained by the Phocians over the Thessalians, under the following circumstances: The Phocians, reduced to extremity by the Thessalians, had resolved, rather than to submit to the enemy, to raise a pile of combustibles, and to burn their wives, children, and effects. This resolution was approved of by the women; but when all was prepared, the Phocians once more engaged the enemy, and utterly routed them. (Plutarch, *De Mul. Virt.*; *Paus*. x. 35; *Athen*. xv.)

ELAPHEBOLION, in *Grecian Antiquity*, the ninth month of the Athenian year, corresponding nearly to our March. It consisted of thirty days, and took its name from the festival Elaphebolia, observed in this month in honour of Diana the huntress. See ELAPHEBOLIA.

ELAPS, a genus of poisonous snakes. See SERPENTS.

ELASTICITY, or ELASTIC FORCE, that inherent property in bodies by which they recover their original figure after any force which has disturbed it is withdrawn. Elasticity is generally accounted for by the great law of attraction. Thus, when a hard body is struck or bent, so that the component parts are moved a little from each other, but not so far as to overcome the power of the attractive force by which they cohere, they necessarily, on the cessation of that external force, return to their former state. All hard bodies are elastic, as steel, glass, and ivory, and many soft ones, as caoutchouc, silk thread, &c. The great elasticity of air is a familiar fact. Liquids are also perfectly elastic, but in the smallest degree.

ELATEA, in *Ancient Geography*, an important town and military stronghold of Phocis, situated in the valley of the Cephissus, on the southern slope of Mount Chemis. By the Athenians Elatea was regarded as the key of southern Greece; and it was its seizure by Philip in 338 B.C., that opened the eyes of that people to the real designs of the

Macedonian prince. The town remained faithful to its conquerors, till with the rest of the Greeks they succumbed to the arms of Rome. Considerable Hellenic remains have been discovered at the small village of Lefta, which occupies the site of Elatea.

ELATERIUM (ἐλαύνειν, *to stimulate*), a drastic purgative medicine, prepared from the wild cucumber. It is chiefly used in the treatment of dropsy.

ELATH, a city of Idumæa. See AKABAH.

ELBA, called ILVA by the Romans, and ÆTHALIA by the Greeks, an island in the Mediterranean Sea lying off the promontory of Populonium, at about equal distances from Corsica and the Italian mainland, though somewhat nearer the latter. Its outline is extremely irregular, and its sides are indented by numerous inlets and arms of the sea, reducing its breadth in some places to about 3 miles. The extreme length of the island is about 18 miles; its extreme breadth about 12 miles; and its area about 150 miles. The whole length of the island is occupied by a mountain range, one peak of which (that of Capanna) rises to the height of about 3500 feet above the sea. The mountains of this range, though themselves barren, inclose valleys of considerable fertility. Vines, olives, and mulberries, grow in large quantities in the island, which also produces wheat, Indian corn, and vegetables in abundance. Some of the wine produced in Elba is of excellent quality, and a considerable quantity of it is annually exported. The smaller domestic animals thrive well and are very numerous in the island; but the larger kinds, such as oxen and horses, are somewhat scarce. The fisheries off the coast are important.

The iron mines of Elba in modern as in ancient times are extremely valuable. The great facility with which the metal is worked, and the abundance in which it is found, render these mines among the most valuable of their kind in the world. The ore is dug from a hill, 500 feet high and nearly 2 miles in circumference, which is itself almost entirely one mass of ore. When smelted, it is found to contain on an average about 60 per cent. of pure iron. Fuel on the island is very scarce; and the ore is consequently conveyed on shipboard to the adjoining mainland to be smelted. The total quantity of iron ore annually extracted amounts to nearly 20,000 tons, giving employment to 130 miners. The salt mines of Elba are hardly inferior in celebrity to the iron ones. About 4,000,000 lbs. are annually produced, giving employment to about 100 workmen. Besides Porto Ferrajo, the capital, and the town of Porto Longone, Elba contains no town of any size or importance. Campo, Capo Liveri, Marciana, and Rio are mere villages or fishing stations. In ancient history the name of Elba very rarely occurs; and in modern times it is chiefly memorable as having been the residence of the Emperor Napoleon after his first abdication from May 1814 till February 1815. From that time till the present Elba has been an appanage of the grand duchy of Tuscany. Pop. (1854) 21,559.

ELBE (the *Albis* of the ancients), a large river of Germany, which rises in the *Riesen Gebirge*, or Giant's Mountains, between Silesia and Bohemia, and is known at its source by the Sclavonic name of the *Labbe*. Its principal sources are the White Fountain, at the base of the *Schnee-Kuppe*, and the eleven fountains of the Elbe in the Navarian meadow. To the number of streams which descend into Bohemia from the neighbouring mountains it owes its early increase. After its junction with the river Eger, it becomes navigable; and, entering Saxony, it passes successively Dresden, Meissen, Torgau, and Wittenberg. In its course, which is northerly, it receives as tributaries the Muldau and the Saale; and running through the territory of Magdeburg and the dúchies of Mecklenburg and Launburg, it discharges itself at last into the German Ocean, about 70 miles below Hamburg, after a course of 500 miles. The Elbe has always been an important river in a military point of view. With respect to commerce, it is of inestimable value to the countries of N.W. and central Germany, being the channel by which they export their surplus products and receive their imports from abroad. It gives to Hamburg its command of the navigation far into the interior, although the voyage is difficult on account of the numerous sand-banks with which the estuary and the rivers are encumbered. It communicates with the Havel by the canal of Plauen, in the territory of Magdeburg; and at Hamburg it is connected in like manner with the Trave at Lubeck. It is also joined to the Weser by a canal running between Vegesak and Stade. By the railway from Leitmeritz to Vienna it communicates with the Danube; and the other railways that touch upon other quarters of the river supply channels for distributing merchandise through the various districts which they traverse.

About 40 miles from its source, the elevation of the river above the level of the sea is only 658 feet; at Schandau it is 341 feet; at Dresden, 279 feet; and at Arneburg in Brandenburg only 176 feet.

Formerly 3 entrepots (Pirna, Dresden, and Magdeburg) and 35 tolls, and numerous corporations of privileged watermen, opposed almost insurmountable difficulties to the navigation: the Austrians and the Saxons could alone navigate the Upper Elbe, that is, from Magdeburg to where it ceases to be navigable, and the Prussians and Hamburgers had the sole privilege of navigating the Lower Elbe. But the navigation of the river was definitively regulated by a convention concluded on the 13th June 1821, between all the bordering states, viz., Austria, Saxony, Prussia, Hanover, Denmark (for Holstein and Lauenburg), the grand duchy of Mecklenburg-Schweren, and the three principalities of Anhalt. This convention established the principle of free navigation, allowing every merchant, to whatever bordering state he might belong, with his own vessel and crew to navigate the whole course of the river without interruption; the 35 tolls were reduced to 14; the heavy dues which were levied upon goods of the first necessity were reduced to those which are paid, one for the cargo (*Elbe Toll*), and the other for the ship (*Recognitionsgebühr*); and each state was bound to watch over the portion of river which passed through their territories, and to preserve it from everything injurious to the commerce or navigation. But notwithstanding these regulations, merchants are still exposed to vexatious burdens and interruptions. Wood, stones, fruits, and earthenware, are the principal articles that are brought down the Elbe. Corn, salt, and colonial produce are the principal articles which are carried up, and on these the greater part of the duties are levied.

Numerous steam-boats now traverse the Elbe, and communicate between that river and London, Rotterdam, Havre, &c.

ELBERFELD, a large manufacturing town of Rhenish Prussia, in the government of Düsseldorf, and 19 miles E. of the town of that name. It is situated in a narrow valley on both sides of the Wapper, and on the Düsseldorf and Dortmund railway. The town is long and straggling, with streets irregular and narrow, and altogether it has a very dirty and unprepossessing appearance. The river too being the receptacle of all the sewers, and the refuse of the dye-works and factories, instead of improving the appearance, adds to the unseemliness of the town. Some of the newer parts of the town, however, are to be excepted from this general description. The town-hall and the new Roman Catholic church are the handsomest buildings in the place. It has numerous educational institutions—among which are the gymnasium and the trade school (*Gewerbschule*),—a general infirmary, two orphan asylums, museum, and library. Elberfeld may be said to have taken its rise almost within the present century. In 1817 its population was only 15,681, while in 1851 it amounted to 39,944. It is at present one of

the first manufacturing and commercial towns in Germany. The great articles of manufacture are silks and cottons, but linen and woollen goods are also made. There are also extensive bleachfields and dye-works. For the dyeing of Turkey red Elberfeld stands unrivalled; and large quantities of yarn are annually sent from Glasgow and other places in the United Kingdom to be dyed, and are again imported to be wrought up.

ELBEUF or Elbœuf, a large manufacturing town of France, in the department of Seine-Inferieure, on the left bank of the Seine, 12 miles S.S.W. of Rouen. The town is generally ill-built, although many improvements have recently been made. The only public buildings worthy of notice are the churches of St Etienne and St Jean-Baptiste; in the latter of which is a stained glass window, presented by the cloth manufacturers of the town about the year 1466, and representing various implements of their craft. Elbeuf has been long celebrated for its woollen manufactures, and is at present the chief seat of that branch of industry in France. Pop. 16,010; more than two-thirds of whom, and also about 2000 of the inhabitants of neighbouring communes, are employed in the manufactures.

ELBING, a fortified seaport-town in the Prussian province of Prussia, government of Danzig, and capital of a cognominal circle on the Elbing, 4 miles from where it flows into the Frische Haff, and 36 miles E.S.E. of Danzig. Pop. (1849) 21,637. The town is surrounded by old walls flanked with towers, and by ditches. It is divided into an old and new town, and has seven gates and eleven suburbs. In the old town the streets are narrow and the houses lofty, but the new town is generally well-built. Elbing has a Roman Catholic, a Calvinist, and five Lutheran churches, a synagogue, six hospitals, orphan and other asylums, a gymnasium, and a library. This town is indebted to Richard Cowle, an Englishman who lived there for some time previous to 1820, for several of its charitable institutions, among which is a school of industry for the maintenance of 400 children. Elbing was founded about the year 1237, and formerly was one of the most important members of the Hanseatic League. It was united to the Prussian dominions in 1772. The chief manufactures are sail-cloth, leather, tobacco, soap, oil, vitriol, pearl ash, starch, chicory, refined sugar, and woollen cloth. The trade is very considerable; but only small vessels can come up to the town, larger ones being obliged to discharge their cargoes at Pillau, at the mouth of the Frische Haff.

ELCESAITES, a Jewish-Gnostic sect who branched off from the Essenes about the time of Trajan. They seem to have derived their name from Elcesai their founder. In their creed they confounded Judaism, Paganism, and Christianity. They rejected the Pentateuch and the Pauline Epistles. They believed their founder had the power of forgiving sin, and observed the Old Testament ceremonial. In the second century they were blended with the Ebionites.

ELCHE, the ancient *Ilici*, a town of Spain, province of Alicante, and 13 miles S.W. of the town of that name. Pop. 15,649. The town, which has a very oriental appearance, being built in the Moorish style, is surrounded by walls, and divided by a ravine over which there is a handsome bridge. The principal church is a fine edifice, surmounted by a majestic dome. There is a magnificent old castle belonging to the Duke of Arcos, on whose estate the town is built. Elche has manufactures of coarse linen and cotton goods. The town is surrounded on all sides by extensive plantations of date palms, the fruit of which constitutes its chief article of export, and is shipped from Alicante as Barbary dates. This is the birthplace of Don George Juan, the travelling companion of Ulloa in South America.

ELCHINGEN, a small village of Bavaria, on the N. bank of the Danube, 7 miles N.W. from Ulm. Here the French under Ney (Oct. 14, 1805) succeeded in forcing the Austrian position; for which service Ney was rewarded with the title of Duke of Elchingen.

ELDER, a title of office among the Jews, first applied to the seventy who assisted Moses in the government. In the New Testament it is equivalent to the term presbyter, and is applied to the highest ecclesiastical office-bearers under the apostles. In Presbyterian churches, elders are of two classes, viz., those who only rule in the church, and those who teach as well as rule. In popular phraseology the term elder is applied only to the former class. See Presbyterians.

ELDORADO (Span. *the Golden Region*), the name given by Orellana, the lieutenant of Pizarro, to a region which he pretended to have discovered in South America, and which he thus named on account of the immense treasures of gold and precious stones he asserted that he had seen at Manoa, the capital of the country. From this fiction, the word Eldorado has become a proverbial term for a region of boundless wealth and felicity, like the Elysium of the ancients, or the paradise of Mohammed.

ELEAZAR, the eldest son of Aaron. He succeeded his father in the high-priesthood, and held the pontificate during the military government of Joshua. This was also the name of one of the Maccabæan brothers, who was crushed to death by the fall of an elephant which he had stabbed in the belief that it carried Antiochus Eupator.

ELEATIC Philosophy, among the ancients, a name given to that of the Stoics, because it was taught at Ἐλέα, (in Latin *Velia*), a town of Lucania.

The founder of this philosophy, or of the Eleatic sect, is supposed to have been Xenophanes, who flourished between B.C. 540 and 500. This sect was divided into two parties, which may be denominated *metaphysical* and *physical*, the one rejecting and the other approving the appeal to fact and experiment. Of the former persuasion were Xenophanes, Parmenides, Melissus, and Zeno of Elea. They are supposed to have maintained principles not very unlike those of Spinoza: they held the eternity and immutability of the world; that whatever existed was only one being; that there was neither generation nor corruption; that this one being was immoveable and immutable, and was God; and that whatever changes seemed to happen in the universe were to be looked upon as mere appearances and illusions of sense. However, it is supposed by some that Xenophanes and his followers, speaking metaphysically, understood by the universe, or the one being, not the material world, but the great originating principle of all things, or the true God, whom they expressly affirm to be incorporeal. Thus Simplicius represents them as merely metaphysical writers who distinguished between things natural and supernatural, and who supposed the former to be compounded of different principles. Accordingly, Xenophanes maintained that the earth consisted of air and fire; that all things were produced from the earth; that the sun and stars sprung from clouds; and that there were four elements. Parmenides also distinguished between the doctrine concerning metaphysical objects, called *truth*, and that concerning physical or corporeal things, called *opinion*. With respect to the former, there was one immoveable principle; but in the latter, two that were moveable, namely, fire and earth, or heat and cold: and in these particulars Zeno agreed with him. The other branch of the Eleatic sect, the Atomic philosophers, formed their system from observing the phenomena of nature: of these the most considerable were Leucippus, Democritus, and Protagoras.

ELECAMPANE, (*Inula Helenium*, Lin.) a perennial plant of a bitter aromatic taste; formerly much used as an expectorant.

ELECTION, in British polity. See Parliament.

ELECTIVE Affinity. See Chemistry.

ELECTRICITY.

Introduction.

Electricity, from the Greek word ηλεκτρον,[1] *electron, amber*, is the name given to a modern science which treats of the phenomena and effects produced by the friction of amber, and other bodies which possess analogous properties.

The science of Electricity, in its most general acceptation, may be divided into four different branches, viz.

I. *Ordinary Electricity*, or that which is developed by friction.

II. *Galvanism*, or that which is produced by chemical action.

III. *Magneto-Electricity*, or that which is developed by magnets; and

IV. *Thermo-Electricity*, or that which is developed by heat.

Under these four articles we shall be able, not only to give a perspicuous and condensed view of those splendid discoveries which have illustrated the present age, but to render our account of them much more complete than if we had treated the subject under the titles of *Electro-magnetism* and *Galvanism*, which occur so early in our alphabetical arrangement.

In giving a succinct and popular view of the science of *Electricity* in the ordinary acceptation of the word, the subject naturally divides itself into two parts: 1*st*, On the phenomena and laws of electricity; and, 2*dly*, on the instruments and apparatus used in electrical experiments. Before we proceed, however, to these topics, we shall give a brief history of the origin and progress of the science.

HISTORY OF ELECTRICITY.

Thales, B. C. 600.

The name of the philosopher who first observed that amber when rubbed possesses the property of attracting and repelling light bodies has not been handed down to our times. Thales of Miletus is said to have described this remarkable property, and both Theophrastus (B. C. 321) and Pliny (A. D. 70) mention the power of amber to attract *straws* and *dry leaves*. The same authors speak of the *lapis lyncurius*, which is supposed to be a mineral called *tourmaline*, as possessing the same property.

Animal electricity.

The electricity of the torpedo was also known to the ancients. Pliny informs us, that when touched by a spear it paralyses the muscles and arrests the feet, however swift; and Aristotle adds that it possesses the power of benumbing men, as well as the fishes which serve for its prey. The influence of electricity on the human body, and the electricity of the human body itself, were also known in ancient times. Anthero, a freedman of Tiberius, was cured of the gout by the shocks of the torpedo; and Wolimer, the king of the Goths, was able to emit sparks from his own body.

A. D. 415.

Eustathius, who records this fact, also states that a certain philosopher, while dressing and undressing, emitted occasionally sudden crackling sparks, while at other times flames blazed from him without burning his clothes.

Such are the scanty gleanings of electrical knowledge which we derive from the ancient philosophy; and though several writers of the middle ages have made occasional references to these facts, and even attempted to speculate upon them, yet they added nothing to the science, and left an open field for the researches of modern philosophers.

History.

Gilbert, A. D. 1600.

Our countryman Dr Gilbert of Colchester may therefore be considered as the founder of the science of electricity, as he appears to have been the first philosopher who carefully repeated the observations of the ancients, and applied to them the principles of philosophical investigation. In order to determine if other bodies possessed the same property as amber, he balanced a light metallic needle on a pivot, and observed whether or not it was affected by causing the excited or rubbed body to approach to it. In this way he discovered that the following bodies possess the property of attracting light substances: Amber, gugates or jet, diamond, sapphire, carbuncle, rock crystal, opal, amethyst, vincentina or Bristol stone, beryl, crystal, paste for false gems, glass of antimony, flags, belemnites, sulphur, gum-mastic, sealing-wax of lac, hard resin, arsenic, sal gem, mica, and alum.

These various bodies attracted, with different degrees of force, not only straws and light films, but likewise metals, stones, earths, wood, leaves, thick smoke, and all solid and fluid bodies. Among the substances which are not excited by friction, Gilbert enumerated emerald, agate, carnelian, pearls, jasper, chalcedony, alabaster, porphyry, coral, marble, Lydian stone, flints, hæmatites, mugris (*emery* or *corundum*), bones, ivory, hard woods, such as cedar, ebony, juniper, and cypress, metals and natural magnets.

Having thus determined the bodies which were capable, as well as those which were incapable, of electrical excitation, Dr Gilbert was desirous of ascertaining the circumstances which were most favourable to the production of electricity. When the wind blew from the north and east, and when the air was dry, the body was excited in about ten minutes after the friction commenced; but when the wind was in the south, and the air moist, the attractive power of the body was greatly diminished, and in some cases it could not be excited at all.

Boyle, A. D. 1675.

The celebrated Mr Boyle added many new facts to the science of electricity, and he has given a full account of them in his *Experiments on the Origin of Electricity*. By means of a suspended needle, he discovered that amber retained its attractive virtue after the friction which excited it had ceased; and though smoothness of surface had been regarded as advantageous for excitation, yet he found a diamond which in its rough state exceeded all the polished ones and all the electrics which he had tried, having been able to move a needle three minutes after he had ceased to rub it. He found also that heat and *tersion* (or the cleaning or wiping of any body) increased its susceptibility of excitation; and that if the attracted body were fixed, and the attracting body moveable, their mutual approach would still take place. To Dr Gilbert's list of electrics Mr Boyle added the resinous cake which remained after evaporating one fourth part of good oil of turpentine; the dry mass which remains after distilling a mixture of petroleum and strong spirit of nitre, glass of antimony, glass of lead, caput mortuum of amber, white sapphire, white amethyst, diaphanous ore of lead, carnelian, and a green stone supposed to be a sapphire.

Otto Guericke, born 1602, died 1686.

To these discoveries of Mr Boyle, his illustrious contemporary Otto Guericke added the highly important one of *electric light*. Having cast a globe of sulphur in a glass sphere, the glass was broken, and the sulphur ball mounted upon a revolving axis, and excited by the friction of

[1] According to Salmasius, the word *karabe*, the Arabian word for *amber*, signifies the power of attracting straws. May not ηλεκτρον (ελκετριανος λιθος) come from ελκω, to *draw* or *attract*, and θριξ-τριχος, a *hair* or *filament*, or θριον, a leaf?

History. the hand. By this means he discovered that light and sound accompanied strong electrical excitation, and he compares the light to that which is exhibited by breaking lump sugar in the dark. With this powerful apparatus Guericke verified on a greater scale the results obtained by his predecessors, and obtained several new ones of very considerable importance. He found that a light body, when once attracted by an excited electric, was repelled by it, and was incapable of a second attraction until it had been touched by some other body; and that light bodies suspended within the sphere of influence of an excited electric, possessed the same properties as if they had been excited.

Newton, born 1642, died 1727. To our illustrious countryman Sir Isaac Newton the science of electricity owes some important observations. He seems to have been the first person who constructed an electrical machine of glass. "A globe of glass," says he, "about eight or ten inches in diameter, being put into a frame where it may be swiftly turned round its axis, will in turning shine when it rubs against the palm of one's hand applied to it; and if at the same time a piece of white paper or a white cloth, or the end of one's finger, be held at the distance of about a quarter of an inch or half an inch from that part of the glass when it is most in motion, the electric vapour which is excited by the friction of the glass against the hand will, by dashing against the white paper, cloth, or finger, be put into such an agitation as to emit light, and make the white paper, cloth, or finger, appear lurid like a glow-worm, and in rushing out of the glass will sometimes push against the finger so as to be felt. And the same things have been found by rubbing a long and large cylinder of glass and amber with a paper held in one's hand, and continuing the friction till the glass grew warm."[1] We owe also to Sir Isaac a beautiful experiment on the excitation of electricity on the side of a disc of glass opposite to the side which was rubbed. Having fixed a round disc of glass at the distance of one third of an inch from one end of a brass hoop or ring, and one eighth of an inch from another, he placed small pieces of thin paper within the brass ring and upon a table, so that the lower surface of the glass was one eighth of an inch distant from the table. He then rubbed the upper surface of the glass, and he observed the pieces of paper "leap from one part of the glass to the other, and twirl about in the air." Upon sliding his finger upon the upper side of the glass, he also observed that the pieces of paper, as they hung under the glass, inclined this way or that according as he moved his finger. The Royal Society had ordered this experiment to be tried at their meeting of the 16th December 1675; and, in order to ensure its success, had obtained the above account of it from Sir Isaac. The experiment however failed, and the secretary requested the loan of Sir Isaac's apparatus, and inquired whether or not he had secured the papers from being moved by the air which might have somewhere stolen in. In Sir Isaac's reply, dated 21st December, he recommended them to rub the glass "with stuff whose threads may rake its surface, and if that will not do, to rub it with the finger ends to and fro, and knock them as often upon the glass." By means of these directions, the society succeeded with the experiment on the 13th January 1676, when they used "a scrubbing brush of short hog's bristles, and the heft of a knife made with whalebone."[2]

Hawksbee, A. D. 1705. Mr Francis Hawksbee, one of the most active and ingenious experimental philosophers of his age, added many new facts to the science. In 1705 he communicated to the Royal Society several curious experiments on what he calls "the mercurial phosphorus." He showed that light could be produced by passing common air through mercury placed in a well-exhausted receiver. The air rushing through the mercury, blew it up against the sides of the glass that held it, "appearing all around like a body of fire, consisting of abundance of glowing globules." The phenomenon continued till the receiver was half full of air. When the mercury was made to descend in vacuo from the top to the bottom of a receiver about twenty-one inches high, it fell in minute particles, "like a shower of fire, in a very surprising manner." In repeating this experiment with about three pounds of mercury, and making it break into a shower by dashing it against the crown of another glass vessel, *flashes resembling lightning*, of a very pale colour, and very distinguishable from the rest of the produced light, were dashed from the crown of the glass, sometimes horizontally, and at other times upwards and downwards Mr Hawksbee likewise showed that considerable light may be produced from mercury, by giving it motion before the receiver was quite exhausted; and that even in the open air "abundance of particles of light are discoverable by shaking quicksilver in a glass."

In a subsequent series of experiments on the attraction of bodies in vacuo, he showed that light was generated by the swift attrition of amber on woollen; that a purple light was produced by the attrition of glass on woollen; and that a considerable light was developed by the attrition of glass on glass in vacuo, and in common air, or under water. During the attrition of glass on woollen, Hawksbee "observed the light to break from the agitated glass *in as strange a form as lightning*," particularly when he used some list of cloth that had been drenched in spirit of wine. In all these experiments Hawksbee was not aware that the light which he observed was that of electricity.

Like Sir Isaac Newton, Hawksbee used a glass globe capable of revolving in a wooden frame, and by its assistance he made a great number of experiments, which are not sufficiently important to be given in detail. The following experiment, however, is too interesting to be omitted. Having coated more than one half of the inside of a glass globe with sealing wax, which in some places was an eighth of an inch thick, and therefore absolutely opaque, he exhausted it and put it in motion. When his hand was applied to excite it, the form of his hand was distinctly seen in the concave surface of the wax, as if it had become transparent. The same result was obtained when pitch or common brimstone was substituted in place of sealing-wax.

We have already seen that Hawksbee observed the resemblance between the electric spark and lightning. Dr Wall went a step farther, and compared the crackling and the flash of excited amber to thunder and lightning. The crackling he found to be fully as loud as that of charcoal on fire when the finger was held at a little distance from the amber after it had been drawn gently and slightly through a piece of woollen cloth.

Mr Stephen Gray, 1720-1736. One of the most ardent experimentalists of the present time was Mr Stephen Gray, a fellow of the Royal Society. In his first paper, published in 1720, he showed that electricity could be excited by the friction of feathers, hair, silk, linen, woollen, paper, leather, wood, parchment, and gold-beaters' skin. Several of these bodies exhibited light in the dark, especially after they had been warmed; but all of them attracted light bodies, and sometimes at the distance of eight or ten inches.

The communication of electricity to bodies not capable

[1] *Optics*, query 8th.

[2] Brewster's *Life of Sir Isaac Newton*, p. 307, 308.

History. Dr Wall, A. D. 1708.

of excitation was the next discovery of Mr Gray. An ivory ball, and various other substances of a metallic, animal, and vegetable nature, were made to attract light bodies by connecting them with strings, wires, or pieces of wood, with one extremity of an excited glass tube; and by suspending pack-threads of different lengths with silken threads, he was able to transmit the electrical influence in any direction to distances of 50, 147, 293, and finally 765 and 886 feet.

In order to determine if the electric attraction is proportioned to the quantity of matter in bodies, Mr Gray and Mr White made two cubes of oak about six inches square, the one solid and the other hollow. When suspended by hair lines, and similarly electrified by an excited glass tube, both the cubes attracted and repelled leaf brass at the same time and to the same height. Hence Mr Gray concluded *that it was the surface of the cubes only which attracted.*

The conducting powers of fluids and of the human body were next ascertained by Mr Gray. Having blown a soap bubble with an electrified tobacco pipe, he found that the lower part of the bubble attracted small pieces of Dutch metal; and when a boy eight or nine years old, and weighing 47 lbs., was suspended upon hair lines, he found that every part of his body exercised a strong electrical action upon light bodies, and hence he concluded "that animals receive a greater quantity of electrical effluvia." When an excited tube was held above water or quicksilver placed in little ivory dishes, the fluid was attracted upwards into little conical mounds, accompanied with a snapping noise and a discharge of light from their summit. In sunshine small particles of water rose from the top of the fluid cone, and sometimes a fine stream of water like a fountain, from which there arose a fine steam or vapour. Hot water was attracted much more powerfully, and at a much greater distance, and the steam was more distinctly visible. Mercury did not rise so high as the water; but the snapping noise was louder, and continued much longer, than when water was employed.

Mr Gray now set himself to discover "whether there might not be a way found to make the property of electrical attraction more permanent in bodies." Having procured iron ladles of several sizes, he melted the substances given in the following table. They were then set by in the ladle to cool and harden, and afterwards being replaced on the fire so as to allow what was next the bottom and sides of the ladle to melt, the ladle was inverted, and the substance taken out. These bodies at first would not attract light substances till their temperature was nearly that of a hen's egg; but when cold they attracted ten times farther than at first. In order to preserve these bodies in a state of attraction, he wrapped them up in flannel or white paper or black worsted stockings, and then put them into a large fir box till they were used. The following is Mr Gray's list of the electrics thus formed:—

Names.	Weight Avoird. oz.	oz.	Time when made.
Fine black rosin	2	0	Jan. 31.
Stone pitch, and black rosin	2	2	Jan. 31.
Fine rosin and bees' wax	2	1	Feb. 1.
Stone pitch	1	7	Feb. 1.
Stone sulphur	3	6	Feb. 4.
Shell lack	10	0	Feb. 10.
Fine black rosin	10	4	Feb. 10.
Bees' wax and rosin	9	0	Feb. 12.
Rosin 4, gum lac 1 part	10	0	Feb. 12.
Sulphur	18	0	Feb. 15.
Stone pitch	10	12	Feb. 16.
Black rosin	23	0	Feb. 23.
White rosin	7	12	Feb. 25.
Gum-lac.	11	14	Feb. 26.
Gum-lac and black rosin	9	12	Feb. 26.
Gum-lac 4, rosin 1 part	17	8	Feb. 28.
Gum-lac, fine black rosin	28	4	March 2.
Cylinder of blue sulphur	19	4	March 20.
Large cone of ditto	30	0	March 29.
Cake of sulphur	11	4	April 29.

M. Dufay, A. D. 1733.

Mr Gray continued for thirty days to observe every one of these bodies, and at the end of that time he found that they attracted as vigorously as at the first or second day, and some of them continued to preserve their attraction for more than four months.

While Mr Gray was pursuing his career of discovery in England, M. Dufay, of the Academy of Sciences, and superintendent of the Royal Botanic Gardens, was actively employed in the same researches. He found that all bodies, whether solid or fluid, could be electrified by an excited tube, by setting them on a glass stand slightly warmed, or only dried; and that those bodies which are in themselves least electrical, received the greatest degree of electricity from the approach of the glass tube. He found that electricity was transmitted more easily along packthread when it was wetted, and that it might be supported upon glass tubes in place of silk lines; and in this way he conveyed it along a string 1256 feet long.

M. Dufay repeated Mr Gray's experiments on the human body, by suspending a child on silken strings; but having suspended himself in a similar manner, he discovered that an electrical spark, accompanied with a crackling noise, took place when any other person touched him, and he has described the prickling sensation like the burning from a spark of fire, which is at the same time felt either through the clothes or on the skin. He found that the same effects took place in other living animals; but that if the carcass of an animal was suspended, there were no snippings or sparks, but merely a still uniform light observed in the dark.

Vitreous and resinous electricity.

The great discovery of M. Dufay, however, was that of two different kinds of electricity, to which he gave the name of *vitreous* and *resinous*, and the importance of which he did not fail to recognise. He has given the name of *vitreous* electricity to that which is produced by exciting *glass*, rock crystal, precious stones, hair of animals, wool, and many other bodies; and the name of *resinous* to that which is produced by exciting resinous bodies, such as amber, copal, gum-lac, silk, paper, thread, and a number of other substances. The characteristic of those two electricities was, that a body with *vitreous electricity* attracted all bodies with *resinous electricity*, and repelled all bodies with *vitreous electricity;* while a body with *resinous electricity* attracted all bodies with *vitreous electricity*, and repelled all bodies with *resinous electricity.* Two electrified silk threads, for example, repel each other, and also two electrified woollen threads, but an electrified silk thread will attract an electrified woollen thread. Hence it is easy to determine whether any body possesses vitreous or resinous electricity. If it *attracts* an electrified silk thread, its electricity will be vitreous; if it *repels* it, it will be resinous. This important discovery seems to have been made about the same time by Mr White, by a series of independent observations.

History.

Mr Gray repeated and varied the experiments of M. Dufay, and made many new ones, which our limited space will not permit us to detail. Like Hawksbee and Dr Wall, he recognised the similarity between the phenomena of electricity and those of thunder and lightning; and he expresses a hope "that there may be found out a way to collect a greater quantity of electric fire, and consequently to increase the force of that power, which, by several of these experiments, *si licet magnis componere parva*, seems to be *of the same nature with thunder and lightning*."

Labours of continental philosophers.

The discoveries which we have now recounted began to rouse the activity of the German and Dutch philosophers. To the electrical machine used by Newton and Hawksbee, Professor Boze of Wittemberg added the *prime* conductor, which at first consisted of an iron or tin tube supported by a man standing upon cakes of rosin; but it was afterwards suspended by silken strings. Professor Winkler of Leipsic substituted the *cushion* in place of the hand for exciting the revolving globe; and Professor Gordon of Erfurt, a Scotch Benedictine monk, first used a glass cylinder, eight inches long and four broad, which he caused to revolve by means of a bow and string. By these means electrical sparks of great size and intensity were produced, and by their aid various combustible substances, both fluid and solid, were inflamed. In 1744 M. Ludolph of Berlin succeeded in firing, by the electrical spark, the ethereal spirit of Frobenius. Winkler did the same by a spark from his finger; and he succeeded in inflaming French brandy and other weaker spirits after they had been heated. Mr Gordon kindled spirits by a jet of electrified water. Dr Miles inflamed phosphorus by the electric spark; and oil, pitch, and sealing-wax, when strongly heated, were set on fire by similar means.

Leyden phial, 1745.

These striking effects were all produced by the electricity obtained immediately from an excited electric; but a great step was now made in the science by the discovery of a method of accumulating and preserving the electric fluid in large quantities. The author of this great invention is not distinctly known; but there is reason to believe that a monk of the name of Kleist, a person of the name of Cuneus, and Professor Muschenbroeck of Leyden, had each the merit of an independent inventor. The invention by which this accumulation was effected was called the *Leyden Jar* or *Phial*, because it was principally in that city where it was either invented or tried. Having observed that excited electrics soon lost their electricity in the open air, and that their loss was accelerated when the atmosphere was charged with moisture or other conducting materials, Muschenbroeck conceived that the electricity of bodies might be retained by surrounding them with bodies which did not conduct it. In putting this idea to the test of experiment, they electrified some water in a glass bottle, and a communication having been made between the water and the prime conductor, while the bottle was held by an assistant, who was trying to disengage the communicating wire, he received a sudden shock in his arms and breast, and thus established the efficacy of the Leyden jar.

Sir William Watson.

Sir William Watson made some important experiments at this period of our history. He succeeded in firing gunpowder by the electric spark; and by mixing the gunpowder with a little camphor he discharged a musket by the same power. He also fired inflammable air by the electric spark; and he kindled both spirits of wine and inflammable air by means of a drop of cold water, and even with ice. In the German experiments the fluid or solid to be inflamed was set on fire by an electrified body; but Sir William Watson placed the fluid in the hands of an electrified person, and set it on fire by causing a person not electrified to touch it with his finger.

Sir William Watson first observed the flash of light which attends the discharge of the Leyden phial, and it is to him that we owe the present improved form of the Leyden phial, in which it is coated both without and within with tinfoil. Dr Bevis indeed had suggested the outside coating, and, at Mr Smeaton's recommendation, he coated a pane of glass on both sides, and within an inch of the edge, with tinfoil; but still the idea of coating the jar doubly belongs to Sir William Watson.

Experiments of the Royal Society of London.

A party of the Royal Society, with the president at their head, and Sir William Watson as their chief operator, entered upon a series of magnificent experiments, for the purpose of determining the velocity of the electric fluid, and the distance to which it could be conveyed. The French sçavans had conveyed the influence of the Leyden jar through a circuit of 12,000 feet; and in one case the basin at the Thuilleries, containing about an acre of water, formed part of the circuit; but the English philosophers made a more complete series of experiments, of which the following were the results:

1. That in all their operations, when the wires have been properly conducted, the electrical commotions from the charged phial have been very considerable only when the observers at the extremities of the wire have touched some substance readily conducting electricity with some part of their bodies.

2. That the electrical commotion is always felt most sensibly in those parts of the bodies of the observers which are between the conducting wires and the nearest and the most non-electric substance; or, in other words, so much of their bodies as comes within the electrical circuit.

3. That on these considerations we infer that the electrical power is conducted between these observers by any non-electric substances which happen to be situated between them, and contribute to form the electrical circuit.

4. That the electrical commotion has been perceptible to two or more observers at considerable distances from each other, even as far as two miles.

5. That when the observers have been shocked at the end of two miles of wire, we infer that the electrical circuit is four miles, viz. two miles of wire, and the space of two miles of the non-electric matter between the observers, whether it be water, earth, or both.

6. That the electrical commotion is equally strong, whether it is conducted by water or dry ground.

7. That if the wires between the electrifying machine and the observers are conducted on dry sticks, or other substances non-electric in a slight degree only, the effects of the electrical power are much greater than when the wires in their progress touch the ground, or moist vegetables, or other substances in a great degree non-electric.

8. That by comparing the respective velocities of electricity and sound, that of electricity, in any of the distances yet experienced, is nearly instantaneous.

In the following year these experiments were resumed with the view of ascertaining the absolute velocity of electricity at a certain distance, and it was found, "that through the whole length of a wire 12,276 feet, the velocity of electricity was instantaneous."

One of the most important discoveries of the present period was that of Sir W. Watson, who proved "that the glass tubes and globes had not the electrical power in themselves, but only served as the first movers or determiners of that power." In rubbing a glass tube while standing upon a cake of wax, he was surprised to observe that no spark could be obtained from his body by any other person touching any part of him. But if a person not electrified held his hand near the tube while it was rubbing, the snapping was very sensible. The great discovery of

plus and *minus* electricity which was afterwards made by Franklin, was distinctly announced by Sir W. Watson. He lays it down as a law, that in electrical operations there is an afflux of electric fluid to the globe and the conductor, and also an efflux of the same matter from them. In the case of two insulated persons, the one in contact with the rubber and the other with the conductor, he observed that either of them would communicate *a much stronger spark to the other than to any bystander. The electricity of the one*, he says, *became more rare than it is naturally, and that of the other more dense*, so that the density of the electricity in the two insulated persons differed more than that between either of them and a bystander.

Our limits will not permit us to give a detailed account of the various ingenious experiments which were about this time made by Le Monnier, Nollet, Winckler, Ellicott, Jallabert, Boze, Menon, Smeaton, and Miles. In 1746 Le Monnier confirmed the result previously obtained by Mr Gray, that electricity is communicated to homogeneous bodies in proportion to their surfaces only. M. Boze discovered that capillary tubes which discharged water by drops afforded a continued stream when electrified. The Abbé Nollet ascertained that electricity increases the natural evaporation of fluids, and that the evaporation is hastened by placing them in non-electric vessels. M. Jallabert confirmed the result previously obtained by Watson, that electricity passes through the substance of a conducting wire, and not along its surface. Smeaton found that the red-hot part of an iron bar could be as strongly electrified as the cold parts on each side of it. Dr Miles kindled common lamp spirits by a stick of black sealing-wax excited by dry flannel. Mr Ellicott conceived that the particles of the electric fluid repel each other, while they attract those of all other bodies. Mr Mowbray discovered that the vegetation of two myrtles was hastened by electrifying them; a result which Nollet confirmed in the case of vegetating seeds. The Abbé Menon found that cats, pigeons, sparrows, and chaffinches, lost weight by being electrified for five or six hours, and that the same result was true of the human body; and hence it was concluded that electricity augments the insensible perspiration of animals.

Discoveries of Franklin, A. D. 1747–1760.

Passing over the scientific fables of John Pivati of Venice, we arrive at that auspicious period when Dr Franklin raised electricity to the dignity of a science, and connected it with that tremendous agency which had so often terrified the moral and convulsed the physical world. The thunderbolt had frequently descended from heaven upon its victims; but mortal genius had now learned to bring it down in chains, to disarm its fury, and to convert it into an useful and even a friendly element.

One of the first labours of the American philosopher was to present, in a more distinct form, the theory of plus and minus electricity, which Sir W. Watson had been the first to suggest. He showed that electricity is not created by friction, but merely collected from its state of diffusion through other matter by which it is attracted. He asserted that the glass globe, when rubbed, attracted the electrical fire, and took it from the rubber, the same globe being disposed, when the friction ceases, to give out its electricity to any body which has less. In the case of the charged Leyden jar, the inner coating of tinfoil had received more than its ordinary quantity of electricity, and was therefore electrified *positively* or *plus*, while the outer coating of tinfoil having had its ordinary quantity of electricity diminished, was electrified *negatively* or *minus*. Hence the cause of the shock and spark when the jar is discharged, or when the superabundant plus electricity of the inside is transferred by a conducting body to the defective or minus electricity of the outside. This theory of the Leyden phial Franklin established in the clearest manner, by showing that the outside and the inside coating possessed opposite electricities, and that, in charging it, exactly as much electricity is added on one side as is subtracted from the other. The copious discharge of electricity by points was observed by Franklin in his earliest experiments, and also the power of points to conduct it copiously from an electrified body. Hence he was furnished with a simple method of collecting electricity from other bodies; and he was thus enabled to perform those remarkable experiments which we shall now proceed to explain.

Hawksbee, Wall, and Nollet had successively suggested the similarity between lightning and the electric spark, and between the artificial snap and the natural thunder. Previous to the year 1750 Dr Franklin drew up a statement, in which he showed that all the general phenomena and effects which were produced by electricity had their counterpart in lightning. Like the electric spark, lightning moves in a crooked and irregular direction. Lightning strikes the highest and most pointed bodies, and electricity does the same. They both inflame combustibles, fuse metals, destroy animal life, produce blindness in animals, render common sewing needles magnetic, and reverse the polarity of needles that have been magnetised. Notwithstanding these points of resemblance, direct experiment was still necessary to establish his views. He waited anxiously for the erection of a spire at Philadelphia, by means of which he might bring down the electricity of a thunder-storm; but his patience being exhausted, he conceived the idea of sending up a kite among the clouds themselves. With this view he made a small cross of two light strips of cedar, the arms being sufficiently long to reach to the four corners of a large thin silk handkerchief when extended. The corners of the handkerchief were tied to the extremities of the cross, and when the body of the kite was thus formed, a tail, loop, and string were added to it. The body was made of silk to enable it to bear the violence and wet of a thunder-storm. A very sharp pointed wire was fixed at the top of the upright stick of the cross, so as to rise a foot or more above the wood. A silk ribband was tied to the end of the twine next the hand, and a key suspended at the junction of the twine and silk. In company with his son, Franklin raised the kite like a common one, in the first thunder-storm, which happened in the month of June 1752. To keep the silk ribband dry, he stood within a door, taking care that the twine did not touch the frame of the door; and when the thunder-clouds came over the kite he watched the state of the string. A cloud passed without any electrical indications, and he began to despair of success. He saw, however, the loose filaments of the twine standing out every way, and he found them to be attracted by the approach of his finger. The suspended key gave a spark on the application of his knuckle, and when the string had become wet with the rain, the electricity became abundant; a Leyden jar was charged at the key, and by the electric fire thus obtained spirits were inflamed, and all the other electrical experiments performed which had been formerly made by excited electrics. In subsequent trials with another apparatus, he found that the clouds were sometimes positively and sometimes negatively electrified, and thus demonstrated the perfect identity of lightning and electricity.

Having thus succeeded in drawing the electric fire from the clouds, Franklin immediately conceived the idea of protecting buildings from lightning, by erecting on their highest parts pointed iron wires or conductors communicating with the ground. The electricity of a hovering or a passing cloud would thus be carried off slowly and

History.

silently; and if the cloud was highly charged, the electric fire would strike in preference the elevated conductors.

Death of Professor Richman, A. D. 1753.

The attention of European philosophers was now directed to the great discovery of Franklin, and various individuals fearlessly sought to repeat his experiments. Among these Professor Richman of St Petersburg was one of the most enterprising. He had undertaken a series of experiments on the electricity of the atmosphere, and for this purpose he had erected an electrical gnomon, which consisted mainly of a Leyden jar, communicating with an iron rod, which rose four or five feet above the roof of his house, and an electrometer formed of a linen thread with half a grain of lead, the angular ascent of which on the face of a divided quadrant indicated the force of the accumulated electricity. On the 9th August 1752 Professor Richman obtained from the end of the rod electrical flashes which could be heard at several feet of distance; and if any person touched the apparatus, a sharp stroke was felt in the hand and arm. On the 31st May 1753 the electric fire exploded from the apparatus with such a force that it was heard at the distance of three rooms from the apparatus. On the 6th August 1753 the professor had prepared and adjusted his apparatus, and having heard the sound of distant thunder, he left a meeting of the Academy of Sciences, and took with him his engineer, Mr Sokolow, to draw any interesting phenomena that might occur. On their arrival at the professor's house, the plummet of the electrometer was elevated four degrees from the perpendicular; and while the philosopher was describing to his friend the dangerous consequences that might take place if the thread should rise to 45°, a tremendous burst of thunder terrified the imperial city. Richman leant his head over the gnomon to observe the indications of the electrometer, and in this stooping position, with his head a foot from the iron rod, a huge globe of bluish-white fire, about the size of Mr Sokolow's fist, shot from the iron rod to the professor's head, with a report like that of a pistol. The blow was fatal; he fell back upon a chest and instantly expired. Sokolow was stupified and benumbed by a sort of steam or vapour, and the red hot fragments of a metallic wire struck his clothes and covered them with burnt marks. As soon as he recovered from his surprise, Sokolow ran out of the house, acquainting every person with the accident which had taken place. In the mean time Madam Richman, alarmed by the thunder-stroke, hastened to the chamber, and found her husband apparently lifeless, in the attitude of sitting upon the chest, and leaning against the wall. Medical aid was instantly obtained, but though a vein was opened, from which no blood would flow, and though every attempt was made to restore life by violent friction and other means, they were all fruitless. A small quantity of blood dropped from the mouth when the body was turned, and on the forehead there was a red spot, from the pores of which a few drops of blood oozed out. Several red and blue spots, like leather shrunk by burning, were found on the left side, the back, and other parts of the body. The shoe upon the Professor's left foot was burst open, and a blue mark appeared on the foot beneath the aperture. There was no corresponding hole in the stocking, and the coat was uninjured. When the body was opened, twenty-four hours after death, there was no appearance of injury either in the brain or the cranium: a little extravasated blood appeared in the cavities below the lungs, and in the lungs towards the back, which were of a dark brown colour. The heart, glands, and smaller intestines, were all inflamed; but the entrails were uninjured. About seventy rubles of silver which were in the left coat pocket were not altered by the electric fluid. Immediately after the accident the house was filled with a sulphureous vapour. A clock which stood in the corner of the adjoining room was stopped; the ashes from the hearth were scattered about the room; the door-case of the room was rent asunder, and a piece of the door itself actually torn off. The Leyden jar was also broken, and the metallic filings which it contained thrown about the room.

Labours of Canton, A. D. 1753.

One of the most active and ingenious labourers in the field of electrical science was our countryman Mr John Canton. Before his time it had been assumed as indisputable that the same kind of electricity was invariably produced by the friction of the same electric; that glass, for example, yielded always *vitreous*, and amber always *resinous* electricity. Having roughened a glass tube by grinding its surface with emery and sheet lead, he found that it possessed vitreous or positive electricity when excited with oiled silk, but *resinous electricity when excited with new flannel.* He found, in short, that vitreous or resinous electricity may be developed at will in the same tube, by altering the surfaces of the tube and the exciting rubber, and according as the one or the other is most affected by their mutual friction. This he illustrated by the very beautiful experiment of removing the polish from one half of the tube. In this case the different electricities were excited with the same rubber at a single stroke, and, what is very curious, *the rubber was found to move much easier over the rough than over the polished half.*

Mr Canton likewise discovered that glass, amber, sealing-wax, and calcareous spar, were all electrified positively when taken out of mercury; and hence he was led to the important practical discovery, that an amalgam of mercury and tin was most efficacious in exciting glass when applied to the surface of the rubber. Mr Canton found also that any body placed within the electric atmosphere of another body acquired the electricity opposite to that of the body in whose atmosphere it was placed; and that the whole air of a room could be electrified either positively or negatively, and made to retain it for a considerable time.

Beccaria, A. D. 1753.

Signor Beccaria, a celebrated Italian, kept up the spirit of electrical discovery in Italy; and in his work on natural and artificial electricity, he has given us the results of many important original investigations. He showed that water is a very imperfect conductor of electricity, that its conducting power is proportional to its quantity, and that a small quantity of water opposes a powerful resistance to the electric fluid. He succeeded in making the electric spark visible in water, by discharging shocks through wires that nearly met in tubes filled with water. In this experiment the tubes, though sometimes eight or ten lines thick, were burst in pieces. Beccaria likewise demonstrated that air adjacent to an electrified body gradually acquired the same electricity; that the electricity of the body is diminished by that of the air; and that the air parts with its electricity very slowly. He considered that there was a mutual repulsion between the particles of the electric fluid and those of air, and that in the passage of the former through the latter a temporary vacuum was formed.

Symmer's experiments, A. D. 1759.

The science of electricity owes several practical as well as theoretical observations to our countryman Mr Robert Symmer. In pulling off his stockings in the evening, Mr Symmer had often remarked that they not only gave a crackling noise, but even emitted sparks in the dark. The electricity was most powerful when a silk and a worsted stocking had been worn on the same leg, and it was best exhibited by putting the hand between the leg and the stockings, and pulling them off together. The one stocking being then drawn out of the other, they appeared more

History.

or less inflated, and exhibited the attractions and repulsions of electrified bodies. Mr Symmer's first trials were accidentally made with *black* silk stockings, but he was surprised to find that *white* ones produced no electricity. Two white silk stockings, or two black ones, when put on the same leg and taken off, gave no electrical indications. When a black and a white stocking were put on the same leg, and at the end of ten minutes taken off, they were so much inflated when pulled asunder, *that each of them showed the entire shape of the leg, and at the distance of a foot and a half they rushed to meet each other.* With worsted stockings, also, nothing but the combination of black and white produced electricity. As it was troublesome to electrify the stockings by putting them on and taking them off the leg, Mr Symmer excited the stockings by drawing them on the hand, which, however, produced a weaker degree of electricity. The electricity was in this case more permanent, and the effects were more powerful, when the stockings were new or newly washed. When an excited white and black stocking are presented to each other, they attract one another, inclining to each other at the distance of three feet, catching hold of each other within two feet, and at a less distance rushing together with surprising violence, becoming as flat as so many folds of silk when they are joined. "But what appears most extraordinary is, that when they are separated, and removed at a sufficient distance from each other, their electricity does not appear to have been in the least impaired by the shock they had in meeting. They are again inflated, again attract and repel, and are as ready to rush together as before. When this experiment is performed with two black stockings in one hand, and two white in the other, it exhibits a very curious spectacle; the repulsion of those of the same colour, and the attraction of those of different colours, throws them into an agitation that is not unentertaining, and makes them catch each at that of its opposite colour, at a greater distance than one would expect. When allowed to come together, they all unite in one mass. When separated, they resume their former appearance, and admit of the repetition of the experiment as often as you please, till their electricity, gradually wasting, stands in need of being recruited."

In the course of these experiments Mr Symmer accidentally threw a stocking out of his hands, and some time afterwards he found it sticking to the paper hangings of the room. They stuck also to the painted pannelling, and often continued for a whole hour suspended upon the hangings.

Mr Symmer's attention was next directed to the force of cohesion between stockings of black and white silk, and he found that from ten ounces to nine pounds weight was necessary to separate the stockings, according to their weight, or according as the rough or smooth surfaces were in contact.

Mr Symmer likewise found that a Leyden jar could be charged by the stockings either positively or negatively, according as the wire from the neck of the jar was presented to the black or white stockings. When the electricity of the white stocking was thrown into the jar, and on that the electricity of the black one, or *vice versa*, the jar will not be electrified at all. With the electricity of two stockings he charged the jar to such a degree that the shock from it reached both his elbows; and by means of the electricity of four silk stockings he kindled spirits of wine in a tea-spoon which he held in his hand, and the shock was at the same time felt from the elbows to the breast. Independent of these curious experiments, Mr Symmer had the merit of having first maintained the theory of two distinct fluids, not independent of each other, as Dufay supposed them to be, but co-existent, and, by counteracting each other, producing all the phenomena of electricity. He conceived that when a body is said to be *positively electrified*, it is not simply that it is possessed of a larger share of electric matter than in a natural state; nor, when it is said to be *negatively electrified*, of a less; but that, in the former case, it is possessed of a larger portion of one of these active powers, and in the latter, of a larger portion of the other; while a body, in its natural state, remains unelectrified, from an equal balance of these two powers within it.

Contemporary with Symmer were Delaval, Wilson, Cigna, Kinnersley, and Wilcke. M. Delaval found that the sides of vessels that were perfect conductors, were non-conductors, and that animal and vegetable bodies lost their conducting power when reduced to ashes. Mr Wilson discovered that when two electrics are rubbed together, the harder of the two is generally electrified positively, and the other negatively, but always with opposite electricities. Cigna made many curious experiments by using silk ribbands in place of the silk stockings of Symmer. Kinnersley, the friend of Franklin, made some important experiments on the elongation and fusion of iron wires, when a strong charge was passed through them in a state of tension; and Wilcke brought to light many new phenomena respecting the spontaneous electricity produced by the melting of electric substances.

Pyro-electricity of minerals.

The pyro-electricity of minerals, or the faculty possessed by some minerals of becoming electric by heat, and of exhibiting negative and positive poles, now began to attract the notice of philosophers. There is reason to believe that the *lyncurium* of the ancients, which, according to Theophrastus, attracted light bodies, was the *tourmaline*, a Ceylon mineral, in which the Dutch had early recognised the same attractive property, whence it got the name of *Aschentrikker*, or attracter of ashes. In 1717 M. Lemery exhibited to the Academy of Sciences a stone from Ceylon which attracted light bodies; and Linnæus, in mentioning the experiments of Lemery, gives the stone the name of *Lapis Electricus*. The Duke de Noya had heard at Naples that Count Pichetti had seen at Constantinople a stone called *tourmaline*, which attracted and repelled light bodies; and in 1758 he purchased some of them in Holland, and, assisted by MM. Daubenton and Adanson, he made a series of experiments with them, which were published separately.

Labours of Æpinus.

This curious subject, however, had engaged the attention of M. Æpinus, a celebrated German philosopher, who published an account of them in 1756. Hitherto nothing had been said respecting the necessity of heat to excite the tourmaline; but it was shown by Æpinus that a temperature between 99½° and 212° of Fahrenheit was requisite for the development of its attractive powers. Mr Benjamin Wilson, Priestley, and Canton, continued the investigation; but it was reserved for the Abbé Haüy to throw much light on this curious branch of the science. He found that the electricity of the tourmaline decreased rapidly from the summits or poles towards the middle of the crystal, where it was imperceptible; and he discovered that if a tourmaline is broken into any number of fragments, when excited, each fragment has two opposite poles. Haüy discovered the same property in the Siberian and Brazilian topaz, borate of magnesia, mesotype, prehnite, sphene, and calamine. He also found that the polarity which minerals receive from heat has a relation to the secondary forms of their crystals, the tourmaline, for example, having its resinous pole at the summit of the crystal which has three faces, and its vitreous pole at the summit which has six faces. In the other pyro-electrical crystals above mentioned, Haüy has detected the same deviation from the rules of symmetry

History.

in their secondary crystals which occurs in tourmaline. Mr Brard discovered that pyro-electricity was a property of the axinite; and more recently Sir David Brewster has detected it, as we shall afterwards see, in a variety of other minerals.

In repeating and extending the experiments of Haüy, Sir David Brewster discovered that various artificial salts were pyro-electrical; and he mentions the tartrate of potash and soda, and the tartaric acid, as exhibiting this property in a very strong degree. He likewise made many experiments with the tourmaline when cut into thin slices, and reduced to the finest powder, in which state each atom preserved its pyro-electricity; and he has shown that *scolezite* and *mesolite*, even when deprived of their water of crystallization, and reduced to powder, preserve their property of becoming electrical by heat. When this white powder is heated and stirred about by any substance whatever, it collects in masses like new fallen snow, and adheres to the body with which it is stirred.

Experiments of Æpinus.

In addition to his experiments on the tourmaline, Æpinus made several on the electricity of melted sulphur; and, in conjunction with Wilcke, he investigated the subject of electric atmospheres, and discovered a beautiful method of charging a plate of air by suspending large wooden boards coated with tin, and having their surfaces near each other, and parallel. Æpinus, however, has been principally distinguished by his ingenious theory of electricity, which he has explained and illustrated in a separate work which appeared at St Petersburg in 1759. This theory is founded on the following principles. 1. The particles of the electric fluid repel each other with a force decreasing as the distance increases. 2. The particles of the electric fluid attract the particles of all bodies, and are attracted by them, with a force obeying the same law. 3. The electric fluid exists in the pores of bodies; and while it moves without any obstruction in non-electrics, such as metals, water, &c., it moves with extreme difficulty in electrics, such as glass, rosin, &c. 4. Electrical phenomena are produced, either by the transference of the fluid from a body containing more to another containing less of it, or from its attraction and repulsion when no transference takes place.

Electricity of fishes.

The electricity of fishes, like that of minerals, now began to excite very general attention. The ancients, as we have seen, were acquainted with the benumbing power of the torpedo, but it was not till 1676 that modern naturalists attended to this remarkable property. The Arabians had long before given this fish the name of *raad* or lightning; but Redi was the first who communicated the fact that the shock was conveyed to the fisherman by means of the line and rod which connected him with the fish. Lorenzini published engravings of its electrical organs; Reaumur described the electrical properties of the fish; Kæmpfer compared the effects which it produced to lightning; but Bancroft was the first person who distinctly suspected that the effects of the torpedo were electrical. In 1773 Mr Walsh and Dr Ingenhouz proved, by many curious experiments, that the shock of the torpedo was an electrical one; and Dr Hunter examined and described the anatomical structure of its electrical organs. Humboldt, Gay Lussac, and M. Geoffroy, pursued the subject with success; and Mr Cavendish constructed an artificial torpedo, by which he was able to produce artificially the actions of the living animal. The subject has been more recently investigated by Dr Todd, Sir Humphry Davy, and Dr John Davy.

The power of giving electric shocks has been discovered also in the *Gymnotus Electricus*, the *Silurus Electricus*, the *Trichiurus Indicus*, and the *Tetraodon Electricus*. The most interesting and the best known of these singular fishes is the *Gymnotus* or Surinam eel. Its electrical organs have been minutely described by Hunter and Geoffroy; Dr Williamson, Dr Gordon, and Mr Walsh have published interesting details of its electrical powers; and Humboldt has more recently given the most romantic account of the combats which are carried on in South America between the gymnoti and the wild horses in the vicinity of Calabozo.

Mr Cavendish, born 1731, died 1810.

Among the modern cultivators of electricity, our countryman, the late Mr Cavendish, is entitled to a distinguished place. Before he had any knowledge of the theory of Æpinus, he had composed and communicated to the Royal Society a theory of electrical phenomena nearly the same as that of the German philosopher. As Mr Cavendish, however, had carried the theory much farther, and considered it under a more accurate point of view, he did not hesitate to give his paper to the world.

Mr Cavendish made some accurate experiments on the relative conducting power of different substances. He found that the electric fluid experiences as much resistance in passing through a column of water one inch long, as it does in passing through an iron wire of the same diameter 400,000,000 inches long, and hence he concludes that rain or distilled water conducts 400,000,000 times more than iron wire. He found that the water, or a solution of one part of salt in one of water, conducts a hundred times better than fresh water; and that a saturated solution of sea-salt conducts seven hundred and twenty times better than fresh water. Mr Cavendish likewise determined by nice experiments that the quantity of electricity in coated glass of a certain area increased with the thinness of the glass; and that in different coated plates the quantity was as the area of the coated surface directly, and as the thickness of the glass inversely.

Chemical electricity.

Although electricity had been employed as a chemical agent in the oxidation and fusion of metals, yet it is to Mr Cavendish that we owe the first of those brilliant enquiries which have done so much for the advancement of modern chemistry. By means of the electric spark he succeeded in decomposing atmospheric air. By using different proportions of oxygen and hydrogen, and examining the product which they formed after explosion with the electric spark, he obtained a proportion when the product was pure water. He was equally successful in the more difficult experiment of exploding oxygen and nitrogen; but when he combined seven measures of oxygen with three measures of nitrogen, he obtained from their explosion *nitric acid*. As several foreigners had failed in repeating this interesting experiment, Mr Cavendish, aided by Mr Gilpin, exhibited it publicly before the leading members of the Royal Society on the 6th of December 1787.

The decomposition of water by the electric spark was first effected by MM. Paets, Troostwyk, and Deiman; and improved methods of doing it were discovered and used by Dr Pearson, Mr Cuthbertson, and Dr Wollaston.

Galvanism and Voltaic electricity.

As a chemical agent, however, electricity was now destined to transfer its supremacy to another science. The great discovery made by Galvani in 1790, that the contact of metals produced muscular contraction in frogs, and the invention of the Voltaic pile, in 1800, by M. Volta of Como, have led to the establishment of a new science, called *Galvanism* or *Voltaic Electricity*, which, though now proved to be identical with common electricity, requires to be treated in a separate article. The chemical effects of the Voltaic pile far transcended those of ordinary electricity, and enabled Sir Humphry Davy to decompose the earths

History.

and the alkalies, and thus to create a new epoch in the history of chemistry.

Coulomb, born 1736, died 1806.

Contemporary with Mr Cavendish was M. Coulomb, one of the most eminent experimental philosophers of the last century. Anxious to determine the law of electrical action, he invented for this purpose an instrument called a *torsion balance*, which has since his time been universally used in all delicate researches, and which is particularly applicable to the measurement of electrical and magnetical actions. Æpinus and Cavendish had considered the action of the electrical fluid as diminishing with the distance; but M. Coulomb proved, by a series of elaborate experiments, that it varied like gravity in the inverse ratio of the square of the distance. Our countryman Dr Robison had previously determined, without, however, having published his experiments, that in the mutual repulsion of two similarly electrified spheres, the law was slightly in excess of the inverse duplicate ratio of the distance, while in the attraction of oppositely electrified spheres the deviation from that ratio was in defect; and hence he justly concluded that the law of electrical action was similar to that of gravity.

Adopting the hypothesis of two fluids, Coulomb investigated experimentally and theoretically the distribution of electricity on the surface of bodies. He determined the law of its distribution between two conducting bodies in contact; he measured the density of the electricity in different points of two globes in contact; he ascertained the distribution of electricity among several globes (whether equal or unequal) placed in contact in a straight line; he measured the distribution of electricity on the surface of a cylinder, and its distribution between a globe and cylinder of different lengths but of the same diameter. His experiments on the dissipation of electricity possess also a high value. He found that the momentary dissipation was proportional to the degree of electricity at the time; and that when the electricity was moderate, its dissipation was not altered in bodies of different kinds or shapes. The temperature and pressure of the atmosphere did not produce any sensible change; but the dissipation was nearly proportional to the cube of the quantity of moisture in the air. In examining the dissipation which takes place along imperfectly insulating substances, he found that a thread of gum-lac was the most perfect of all insulators; that it insulated ten times better than a dry silk thread; and that a silk thread covered with fine sealing-wax insulated as powerfully as gum-lac when it had four times its length. He found also that the dissipation of electricity along insulators was chiefly owing to adhering moisture, but in some measure also to a slight conducting power.

Experiments of Laplace, Lavoisier, and Volta, 1781.

Towards the end of the last century a series of experiments was made by MM. Laplace, Lavoisier, and Volta, from which it appeared that electricity is developed when solid or fluid bodies pass into the gaseous state. The bodies which were to be evaporated or dissolved were placed upon an insulating stand, and made to communicate by a chain or wire with a Cavallo's electrometer, or with Volta's condenser, when it was suspected that the electricity increased gradually. When sulphuric acid diluted with three parts of water was poured upon iron filings, inflammable air was disengaged with a brisk effervescence; and at the end of a few minutes the condenser was so highly charged as to yield a strong spark of negative electricity. Similar results were obtained when charcoal was burnt on a chafing dish, or when fixed air or nitrous gas was generated from powdered chalk by means of the sulphuric and nitrous acids.

Volta.

M. Volta, who happened to be at Paris when these experiments were made, and who took an active part in them, had subsequently observed that the electricity produced by evaporation was always negative. He found that burning charcoal gives out negative electricity; and in other kinds of combustion he obtained distinct electrical indications.

Saussure.

In this state of the subject M. Saussure undertook a series of elaborate experiments on the electricity of evaporation and combustion. In his first trials he found that the electricity was sometimes positive and sometimes negative when water was evaporated from a heated crucible of iron; but he afterwards found it to be always positive both in an iron and a copper crucible. In a silver and in a porcelain crucible the electricity was negative. The evaporation of alcohol and of ether in a silver crucible also gave *negative* electricity. M. Saussure made many fruitless trials to obtain electricity from combustion, and he likewise failed in his attempts to procure it from evaporation without ebullition.

Many valuable additions were about this time made to electrical apparatus, as well as to the science itself, by Van Marum, Cavallo, Nicholson, Cuthbertson, Brooke, Bennet, Read, Morgan, and Henley; but our limits will not permit us to do any thing more than thus notice their labours.

Application of analysis to electricity.

The application of analysis to electrical phenomena may be dated from the commencement of the present century. Coulomb had considered only the distribution of electricity on the surface of spheres; but Laplace undertook to investigate its distribution on the surface of ellipsoids of revolution, and he showed that the thickness of the coating of fluid at the pole was to its thickness at the equator as the equatorial is to the polar diameter, or, what is the same thing, that the repulsive force of the fluid, or its tension at the pole, is to that at the equator as the polar is to the equatorial axis.

M. Biot.

M. Biot has extended this investigation to all spheroids differing little from a sphere, whatever may be the irregularity of their figure. He likewise determined analytically that the losses of electricity form a geometrical progression when the two surfaces of a jar or plate of coated glass are discharged by successive contacts; and he found that the same law regulates the discharge when a series of jars or plates are placed in communication with each other.

M. Poisson.

It is to M. Poisson, however, that we are mainly indebted for having brought the phenomena of electricity under the dominion of analysis, and placed it on the same level as the more exact sciences. By assuming the hypothesis of two fluids, he has deduced theorems for determining the distribution of the electric fluid on the surface of two conducting spheres when they are either placed in contact or at any given distance; and the truth of these theorems has been established by experiments performed by Coulomb long before the theorems themselves had been investigated.

Oersted's discovery of electro-magnetism, 1820.

The cultivation of the new science of Voltaic electricity had now withdrawn the attention of experimental philosophers from that of ordinary electricity. The splendour of its phenomena, as well as its association with chemical discovery, contributed to give it popularity and importance; but the discoveries of Galvani and Volta were destined, in their turn, to pass into the shade, and the intellectual enterprise of the natural philosophers of Europe was directed to new branches of electrical and magnetical science. Guided by theoretical anticipations, Professor H. C. Oersted of Copenhagen, in 1820, laid the foundations of the science of *Electro-magnetism*. He found that the electrical current of a galvanic trough, when made to pass through a platina wire, acted upon a compass needle placed below the wire; and upon repeating

History.

the experiment, he discovered the fundamental law, that *the magnetical effect of the Voltaic current had a circular motion round the current*, or round the *conductor*, or the wire through which the current passed. M. Ampere of Paris soon afterwards made the important discovery, that two wires conducting electrical currents, when suspended so as to be capable of motion, *attracted* each other when the currents moved in the *same direction*, and *repelled* each other when they moved in *opposite* directions; or, to express the fact more simply, *two points of electrical currents repel each other by their similar sides, and attract each other by their opposite sides;* so that, as Professor Oersted remarks, *an electric current contains a revolving action, exhibiting every appearance of polarity*.

Discoveries of Ampere.

Discoveries of Arago, Davy, and Seebeck.

In 1820 M. Arago, Sir H. Davy, and Dr Seebeck of Berlin, without being acquainted with each other's labours, discovered the power of the electric current to impart magnetism to iron and steel needles; but the most singular discovery on this branch of the subject was made by M. Savary, who found that small steel needles placed at different but very short distances from a wire conducting an electrical current, are magnetised in different directions. Needles in contact with the wire are magnetised in the usual or *positive* direction; while needles at the distance of 1·1 millimeter, or $\frac{1}{24}$th of an inch, are magnetised in an opposite direction, which he calls *negative*. At the distance of two inches from the wire there was a neutral line in which the needles were not magnetised at all. When the distance of the unmagnetised needle was increased from three to eight millimeters it again became positively magnetic, the maximum effect taking place at the distance of $5\frac{1}{2}$ millimeters. Between the distance of 8·6 and 21·4 millimeters the magnetism was a second time negative, the effect increasing from 8·6 to 14·6, and again reaching the vertical or zero point at 21·4. Beyond the distance of twenty-three millimeters the magnetism was again positive. With different conducting wires M. Savary found, that within certain limits the maximum intensity is produced at a greater distance from the wire, and the number of alternations of positive and negative direction is also greater in proportion, as the wire is shorter in proportion to the length of the helix. When needles are placed parallel to the axis of a helix of narrow windings, they all receive the same kind of magnetism; but when the electrical charge is increased from one jar to a battery of twenty-two superficial feet, six alternations, viz. three positive and three negative, are obtained. When Voltaic electricity is substituted for ordinary electricity, the alternations are destroyed by a continued current, but appear when the current is established only for an instant.

Discoveries of M. Savary.

Discoveries of Professor Erman.

These curious experiments were followed by those of Professor Erman of Berlin, who found that when an electrical discharge passes through the centre of a circular disc of steel, and in a line perpendicular to its surface, no apparent magnetism is developed; but when a slit is made in the plate, or a sector cut out of it, the side of the disc opposite to the slit, or the sectoral opening, exhibits the opposite magnetism. MM. Gay Lussac and Welther obtained the same result with a steel ring.

Discoveries of Dr Seebeck, 1822.

The discovery of thermo-electricity by Dr Seebeck in 1822 gave a new impulse to this branch of science. In studying the influence of heat in Galvanic arrangements, he was led to believe that magnetism might be developed in two metals forming a circuit when the equilibrium of heat in them was disturbed. He accordingly joined a semicircular piece of bismuth with a similar piece of copper, so as to form a circle by their union; and when one of the junctions was heated an electrical current was produced, which could show its existence only by the magnetic needle, and which exhibited all the magnetical properties of an electrical current.

Dr Faraday's discoveries.

In the same year in which Dr Seebeck made this remarkable discovery, the rotation of a magnetical needle round an electrical current, and of a body transmitting an electrical current round a magnet, were exhibited in a series of beautiful and highly ingenious experiments by Dr Faraday, whose subsequent discoveries place him at the head of the cultivators of this most interesting science.

Experiments of Arago and others.

These experiments were followed by those of Arago, Barlow, Seebeck, Herschel, and Babbage, in which a revolving plate of copper gives a rotatory motion to a magnetic needle conveniently suspended; but notwithstanding the ingenuity and talent with which this subject was treated by these eminent individuals, it is to Dr Faraday that we owe a complete analysis and explanation of this curious phenomenon.

Discovery of magneto-electricity by Dr Faraday.

This explanation was founded on the great discovery of the evolution of electricity from magnetism, by which Dr Faraday laid the foundation of the new science of magneto-electricity. By means of a series of simple and beautiful experiments with the celebrated magnets of Dr Gowin Knight, and with the powerful magnet of Professor Daniel, Dr Faraday obtained the most unequivocal and striking electrical effects, though the intensity of the electricity was very feeble, and its quantity small. He obtained a distinct though feeble spark; he succeeded in convulsing the limbs of a frog by means of a magnet; and he perceived also the sensation on the tongue and the flash before the eyes, but he could not effect chemical decomposition by magnetism. Besides obtaining these important results, Dr Faraday has clearly established the laws according to which a magnet developes magnetic currents. He applies these laws to the explanation of the reciprocal action of revolving magnets and metals, and he adduces unquestionable proofs of the production of electricity by terrestrial magnetism.

These important results have been more recently extended by Dr Faraday and others. M. Pixii observed attractions and repulsions in the electricity evolved by magneto-electric induction; and by an ingenious and powerful apparatus he obtained a great degree of divergence in the gold leaves of an electrometer. At the meeting of the British Association at Oxford in June 1832, Dr Faraday, by means of Mr Snow Harris's electrometer, subsequently described, succeeded in heating a wire by magneto-electric induction. By means of the magneto-electric apparatus of M. Pixii already referred to, he and M. Hachette decomposed water, and obtained the oxygen and hydrogen in separate tubes.

Identity of the various electricities established by Dr Faraday.

In the progress of his electrical researches, Dr Faraday found it necessary for their further prosecution to establish either the identity or the distinction of the electricities excited by different means; and in a paper of great value, he has established beyond a doubt the identity of common electricity, Voltaic electricity, magneto-electricity, thermo-electricity, and animal electricity. The phenomena exhibited in these five kinds of electricity do not differ in kind, but merely in degree; *and in this respect they vary in proportion to the variable circumstances of quantity and intensity, which can at pleasure be made to change in almost any one of the kinds of electricity, as much as it does between one kind and another.* Dr Faraday has given the following interesting table of the experimental effects common to the electricities derived from different sources.[1]

[1] The cross indicates that the effect at the top of this table is produced by the electricity mentioned in the column at the side.

Relation by measure of ordinary and voltaic electricity.

Dr Faraday was anxious to determine the relation by measure of ordinary and voltaic electricity; and after various excellent experiments, he obtained as an approximation, and judging from magnetical force only, "that two wires, one of platina and one of zinc, each one-eighteenth of an inch in diameter, placed five-sixteenths of an inch apart, and immersed to the depth of five-eighteenths of an inch in acid consisting of one drop of oil of vitriol, and four ounces distilled water at a temperature about 60°, and connected at the other extremities by a copper wire eighteen feet long and one-eighteenth of an inch thick (being the wire of the galvanometer coils), yield as much electricity in eight beats of my watch, or in $\frac{8}{150}$ths of a minute (or 3·2 seconds), as the electrical battery (of fifteen jars) charged by thirty turns of the large machine in excellent order. The same result was found to be true in the case of chemical force."

Dr Faraday's new law of electrical conduction.

In the course of his investigations relative to electro-chemical composition, Dr Faraday was led to observe the effects due to a very general law of electric conduction which had not formerly been recognised. He found that solid bodies assume the power of conducting electricity during liquefaction, and lose this conducting power during congelation. The voltaic electricity produced by a battery of fifteen troughs, or a hundred and fifty pairs of four-inch plates powerfully charged, was incapable of passing through a thin film of ice three-sixteenths of an inch thick; but when the ice was melted, the electricity passed in such quantities as to deflect the magnetic needle 70°. This insulation, however, exhibited by ice is not effective with electricity of exalted intensity. In making this experiment with other solid bodies, Dr Faraday chose those which, being solid, at common temperatures, were fusible, and of such a composition as, for other reasons connected with electro-chemical action, led to the conclusion that they would be able to replace water. When the electric current passed through the solid body employed, there was no chemical decomposition; but when the body was liquefied or fused, the decomposition took place. The bodies which Dr Faraday found to be subject to this law will be found in our section on Electrical Conduction. The degree of conducting power conferred upon bodies by liquidity is generally very great. In water it is the feeblest of all; and in the various oxides, chlorides, salts, &c. it is given in a much higher degree, some a hundred times greater, than in the case of pure water.

Faraday's theory of statical electricity.

In studying the phenomena of induction, Mr Faraday has been led to a beautiful theory of inductive action, which throws a new light upon every department of electricity. While Cavendish, Poisson, and other distinguished cultivators of the science have considered induction as a force excited at a distance, and in straight lines, he has been led to regard it as an *action of contiguous particles*, or particles near each other, consisting of a species of polarity in the particles of the *dielectric* or insulating medium through or across which the electric forces are acting. When an electrified body induces electricity in a conductor, it does it by *polarizing* all the intermediate particles of the dielectric, that is by exciting the opposite electricities in the particles near it, and by these particles producing the same effect from particle to particle, till it is transferred to the conductor. The particles which are thus polarized are not supposed to be material atoms of the dielectric, but merely points or centres of force pervading all space and penetrating all material bodies. When such contiguous particles communicate their forces slowly to one another, *insulation* or *coercion*, as it has been called, is produced; and when rapidly, conduction is the result. This polarization of dielectrics has been placed beyond a doubt by the experiments of Faraday and Matteucci in the case of solids and fluids, if not for air and the gases. By means of this fine theory, which has been confirmed by recent experiments, M. Mosotti has succeeded in explaining the law of electrical forces discovered by Coulomb.

Researches of M. Plana.

In an able memoir published at Turin in 1845, M. Plana has given the results of his researches on the distribution of the electric fluid on the surface of conductors. Without taking into consideration the cause of the retention of electricity on the surface of conductors, he has treated the problem of its distribution in three cases,—in the case where the spheres are in contact, in the case where they are separated by any interval, and in the case where the separation is very small compared with the distance of their centres. He has also given a more rigorous demonstration of certain principles, on the relations which exist between the thickness of the electric wire and the forces which emanate from it. From the simple fact, that free electricity distributes itself on the surface of conductors, he demonstrates that the repulsive force in the case of simple physical points is inversely as the square of the distance.

Researches of Cavendish.

The distribution of electricity on spherical conductors has been successfully pursued by English mathematicians. Our celebrated countryman Mr Cavendish had, so early as 1773, made great progress in the inquiry. He demonstrated the remarkable proposition, that unless the electrical force was in the inverse proportion of the square of the distance, the electricity would be distributed through the interior of a charged conductor; and consequently that this law must be true, as the electricity is confined to an infinitely thin film on its surface. We owe also to Cavendish an approximation to the true theory of the Leyden phial, and a determination of the effects produced by connecting conductors with fixed wires.

Researches of Mr Green.

It is by our countryman Mr Green, a self-taught mathematician, that the greatest advances have been made in the mathematical theory of electricity.[1] "His researches," as Professor William Thomson has observed, "have led to the elementary proposition which must constitute the legitimate foundation of every perfect mathematical structure that is to be made from the materials furnished in the experimental laws of Coulomb. Not only do they afford a natural and complete explanation of the beautiful quantitative experiments

[1] *Essay on the application of Mathematical Analysis to the Theories of Electricity and Magnetism*, Nottingham, 1828.

History.

which have been so interesting at all times to practical electricians, but they suggest to the mathematician the simplest and most powerful methods of dealing with problems which, if attacked by the mere force of analysis, must have remained for ever unsolved." One of the simplest applications of these theorems was to perfect the theory of the Leyden phial, a result which (if we except the peculiar action of the insulating solid medium since discovered by Mr Faraday) we owe to his genius. He has also shown how an infinite number of forms of conductors may be invented, so that the distribution of electricity in equilibrium on each may be expressible in finite algebraical terms,—an immense stride in the science, when we consider that the distribution of electricity on a single spherical conductor, an uninfluenced ellipsoidal conductor, and two spheres mutually influencing one another, were the only cases solved by Poisson; and, indeed, the only cases conceived to be solvable by good mathematical writers.

Researches of Prof. William Thomson.

The work of Mr Green, which contained these fine researches, though published in 1828, had escaped the notice not only of foreign, but even of British mathematicians; and it is a singular fact in the history of science, that all his general theorems were rediscovered by Professor William Thomson of Glasgow, MM. Charles and Sturm of Paris, and M. Gauss of Göttingen. Professor Thomson, however, pushed his researches much farther than his fellow-labourers. He pointed out in 1845 the consistency of Mr Faraday's experiments with the new theory; and, guided by an analogy between the uniform motion of heat and the distribution of electricity on conductors, or the attractive and repulsive forces excited by electrified bodies, he has shown how the peculiar electric polarization discovered by Mr Faraday in dielectrics, or solid insulators subjected to electric force, is to be taken into account in the theory of the Leyden phial, so as to supply the deficiency in Green's investigations.[1]

From the elementary propositions of Mr Green, Mr Thomson was led to the beautiful principle of what he calls *electrical images*, which is a new and admirable method of treating a great variety of problems in reference to the distribution of electricity on spherical conductors. "The effect," says Mr Thomson, "of a body electrified in any given manner upon an uninsulated sphere, is shown to be completely represented by what may be called *the image* of the *electrified body in the sphere;* and a simple geometrical construction is given by which this image may be described. When an electrified body is placed in the neighbourhood of two uninsulated spheres, an inductive effect is produced which may be represented by an infinite series of *successive images* in each sphere. An algebraic expression of this result leads to solutions, by means of converging series, of the various problems which occur with reference to the distribution of the induced electricity, and the attractions exerted by the two spheres. Or, when a single conductor, bounded by segments of two spherical surfaces cutting at an angle which is a submultiple of two right angles, is electrified by the influence of a charged body, the effect may be represented by a finite number of images disposed in a symmetrical manner in the circumference of a circle passing through the exciting body, and cutting the two spherical surfaces at right angles. The principle of electrical images in these two cases may be illustrated by a reference to the successive images of a candle placed between two parallel plane mirrors, and to the symmetrically arranged images which are seen in the kaleidoscope."[2]

Mr Armstrong's hydro-electric machine.

One of the most remarkable discoveries in electricity which has been made in our own day is that of the hydro-electric machine, which we owe to Mr Armstrong of Newcastle. On the 29th September 1840 William Paterson, who attended a steam-engine at Cramlington Colliery, 8 miles from Newcastle, happening to take hold with one hand of the lever of the safety valve of the boiler, while his other hand was in the steam which was issuing from a fissure, received an electric shock. The same effect was produced if he touched any part of the boiler, or any iron work connected with it. The engine-man also found that when one hand was immersed in the jet of steam he gave a shock to every person he touched with the other, whether the person was in contact with the boiler or merely stood on the brick-work which supports it, though the shock was greater when the person touched the boiler. Having heard of these remarkable facts, Mr Armstrong went to Cramlington Colliery and observed the phenomena, and having constructed a steam apparatus, he found that the place where the electricity was produced was that at which the steam was subjected to friction, and that when the boiler was of wrought iron the electricity was always *positive*, excepting when he made the steam pass to the discharging aperture through a considerable surface of polished brass. In this case the electricity became very feeble; but when the inside of the brass tube was moistened with dilute nitric acid, the steam from the iron boiler became for the first time *negatively* electrified. By an insulated brass discharging-rod, consisting of a metallic plate at one end and a brass ball at the other, he obtained from 60 to 70 powerful sparks in a minute, the plate being plunged in the issuing steam, and the ball brought into contact with the boiler. Mr Armstrong was thus led to construct a hydro-electric machine, which gives sparks 22 inches long, and so large, dense, and rapid that they frequently resembled a continuous flame. This machine, with a boiler $6\frac{1}{2}$ feet long by $3\frac{1}{2}$ feet wide, was constructed for the Polytechnic Institution, where it has long excited the admiration of the public.

Mr Faraday's explanation of the hydro-electric machine.

Mr Armstrong at the very commencement of his inquiry communicated his discovery to Mr Faraday, who, with his usual ability, investigated the theory of the machine. He found that the electricity was produced by the friction of the particles of water upon the discharging tube, and that it was not the electricity caused by evaporation. When tubes of glass, metal, or wood were used, the electricity of the steam was always negative, and that of the boiler positive, but when a quill tube or a tube of ivory was employed, "the boiler received scarcely any charge, and the stream of steam was also in a neutral state," showing that the electricity was not produced by evaporation. Mr Faraday also found that the electricity of the issuing current was *negative*, and that of the boiler *positive*, when oil or oil of turpentine was carried forward by the current of steam. When acetic acid was used in the steam globe, the electricity was neutralized.

Researches of Sir Snow Harris.

Among the able and active cultivators of electrical science, Sir Snow Harris deserves a prominent place. He was the first who introduced accurate quantitative measures into the investigation of the laws of statical electricity—the unit measure by which quantity is minutely estimated—and the hydro-electrometer and scale-beam balance by which its intensity and the laws of attractive forces at all distances are demonstrated. Of not less value is the thermo-electrometer, by which the heating effects of given quantities of electricity are measured and rendered comparable with the varying conditions of quantity and intensity. Besides these instruments, we owe to the same philosopher the discovery of a new reactive force, by which repulsion and other small physical forces are investigated and determined by means of his bifilar balance, founded upon the reactive force of two vertically suspended parallel threads when twined upon each

[1] See *Cambridge and Dublin Mathematical Journal*, Nov. 1845; and *Phil. Mag.*, July 1854, pp. 42–62.

Phenomena and Laws.

other at a given angle, and acted upon by a suspended weight. With the aid of these ingenious instruments he has carried on a variety of successful inquiries into the laws of electrical forces, and the laws and operations of electrical accumulation. In studying the laws of electrical discharge in the form of lightning, Sir Snow Harris was led to the invention of a permanent system of conductors for ships, so perfect that during the last twenty-five years in which they have been introduced into the British navy no instance has occurred of the least damage by lightning. Although the nation has thus gained many thousand pounds per annum, and hundreds of valuable lives been saved, Sir Snow Harris has received only the paltry reward of L.5000. Our limits will not permit us to enumerate the various individuals by whom the science of statical electricity has been advanced, either by their researches or their inventions. Among these we may mention the distinguished names of Peltier, Pouillet, Becquerel, Matteucci, Fusinieri, Grove, Wheatstone, Delarive, Melloni, and Dubois Remond.

PART I.

PHENOMENA AND LAWS OF ELECTRICITY.

Elementary Phenomena and Definitions.

Elementary phenomena and definitions.

1. If a smooth glass tube, or the glass of a watch, or a piece of sealing-wax, or amber, be rubbed upon the sleeve of a cloth coat, or, what is still better, if it be rubbed with a piece of dry flannel or woollen cloth, it will be found to have acquired from this friction a new physical property. This property will be exhibited by holding the body which has been newly rubbed above small shreds of paper, gold leaf, or any thin light substances placed upon the table. These bodies will be instantly *attracted* to it, some of them adhering to its surface, others falling back to the table, and others being thrown off from the body as if they were repelled from it.

The property which has thus been communicated by friction is called *electricity*, the body which acquires the property is called the *electric*, the attraction which it exercises over light bodies is called *electric attraction;* and when the attractive power is produced by friction, the body *rubbed*, or the *electric*, is said to be *excited* by friction, or *electrified* or *electrized*, and the body by which it is excited is called the *rubber*.

2. In order to study these phenomena with more precision, let a small ball B,[1] the size of a pea, made of cork, or the dry pith of elder, or, what is better still, of the finely porous pith of the sola tree from India, be suspended from a stand ACD by a dry silk thread AB, or a fibre of raw silk. Having rubbed a large glass tube with a piece of dry silk, present it to the ball B, and the ball will be instantly attracted to the tube, and will adhere to it. After they have continued in contact for a second or two, withdraw the glass tube, taking care not to toucn the ball with the finger. If the excited glass tube is now a second time brought near the ball, the ball will recede from it, or will be *repelled* by the tube. If, after touching the ball with the finger, so as to deprive it of its electricity, the above experiment is accurately repeated with a stick of *sealing-wax* in place of glass, the very same phenomena will be exhibited; the ball will, in the first instance, be *attracted*, and on the second application of the sealing-wax it will be *repelled*. Hence we draw two conclusions, *first*, that both *glass* and *sealing-wax* attract the ball B before they have communicated to it any of their own electricity; and, *second*, that both these electrics repel the ball after each of them has communicated to it some of their own electricity.

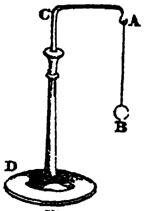

Fig. 1.

3. Let us now examine what takes place when the excited sealing-wax is presented to the ball after the ball has received electricity from the excited glass, and *vice versa*. For this purpose excite the glass tube, present it to the ball B, and after it has been a few seconds in contact, withdraw it. The ball has now received electricity from the glass tube. Let the sealing-wax be now excited and presented to the ball, the ball, in place of being *repelled*, will be *attracted* by the wax. Reverse this experiment, by first presenting the excited wax to the ball, and then the excited glass, and it will be in like manner found that the glass *repels* the ball. Hence it follows that

Excited glass *repels* a ball electrified by excited glass.
Excited wax *repels* a ball electrified by excited wax.
Excited glass *attracts* a ball electrified by excited wax.
Excited wax *attracts* a ball electrified by excited glass.

From which we conclude that there are two opposite electricities, namely, that produced by excited glass, to which the name of *vitreous* or *positive* electricity has been given, and that produced by excited wax, to which the name of *resinous* or *negative* electricity has been given.

4. If, when the pith ball B is electrified, either with excited glass or wax, we touch it with a rod of glass, its property of being subsequently attracted or repelled by the excited glass or wax will suffer no change; but if we touch it with a rod of metal it will lose the electricity which it had received, and will be attracted both by the excited glass or wax, as it was when they were first applied to it. Hence the rod of glass and the rod of metal possess different properties, the former being incapable, and the latter capable, of carrying off the electricity of the pith ball. The metal is therefore said to be a *conductor*, and the glass a *non-conductor*, of electricity.

In the few elementary experiments which we have now described, the electricity has been produced by *friction;* but the pith ball could have been electrified by a great variety of other methods, which will be explained in a subsequent part of this article. In all these cases the effects are precisely the same, whatever be the source from which the electricity is obtained; but as friction is the simplest means of generating electricity, and as machines and apparatus have been invented, by means of which it can be thus produced in great abundance, and accumulated in large quantities, we shall proceed to describe the phenomena and laws of electricity as produced by friction.

CHAP. I.—ON THE PHENOMENA OF ELECTRICITY PRODUCED BY FRICTION.

SECT. I.—*Description of the Electrical Machine for generating Electricity.*

Although the friction produced by the strength of the human arm is sufficient to produce abundance of electricity for ordinary experiments, yet the aid of mechanism has been found essential for carrying on electrical investigations, and producing powerful electrical effects. The various forms which have been given to the electrical machine will be described in the second part of this article, under the head of Electrical Apparatus, so that we shall chiefly confine our attention at present to a description of the plate-glass machine.

This machine, in its common form, is represented in Plate CCXXII., fig. 1, where AB is a circular disc of plate- Plate CCXXII., fig. 1.

[1] Light hollow metallic balls, or pith balls covered with gold or silver leaf, are preferable in certain experiments.

Phenomena and Laws.

glass from eighteen inches to two or more feet in diameter, and from two to three eighths of an inch thick. This disc is fixed perpendicular to a horizontal axis, supported by two uprights E, F, of a mahogany frame, and is capable of being turned round with any ordinary degree of velocity, by means of the handle or winch W. The rubbers by which this disc of glass is rubbed or excited are placed at the upper and lower end of the disc, as seen in the section, fig. 2. The two upper rubbers above A, viz. G, H, are suspended from the top of the frame, and are fixed by screws to two flat pieces of wood *m*, *m*, which can be pressed together or slackened by turning the screw *s* so that the rubbers G, H may be made to press with the requisite degree of force against the disc AB which revolves between them. The lower rubbers M, N below B, are supported upon the stand, and are similarly put together. The rubbers are generally flat cushions of silk or soft leather stuffed with hair.

Rubbers.

Prime conductor.

The prime conductor CD is a semicircle of hollow brass, supported on the upright E by means of the solid glass cylinder R. The two extremities of this conductor, one of which is seen below A, and the other above B, carry each a row of brass points, and the transverse piece of brass tube in which the points are inserted terminates in a varnished wooden ball.

Silk flaps.

From the upper rubbers an oil silk flap, embracing both surfaces of the plate, extends to a little above the row of points on the conductor; and from the lower rubbers a similar flap extends to a little below the other row of points. One of these flaps is seen in the figure, but the other is partially hid by the upright F.

Amalgam.

As it has been found that electricity is developed more copiously when the rubbers are covered with an amalgam of one part of tin and two of mercury, various compositions have been tried by philosophers.[1] The following amalgam, recommended by Singer, is equal in efficacy to any that has yet been proposed. Melt two ounces of zinc and one of tin, and pour into the crucible six ounces of mercury. Shake the whole together till it is cold, in an iron or thick wooden box; and when it has been reduced to a fine powder in a mortar, mix it with as much lard as will form it into a paste. The amalgam thus formed must then be thinly spread on the surface of each cushion; and when the disc of glass has been well cleaned from dust, and from black specks or lines, by means of a little spirits of wine, the mixture is ready for use.

When a very powerful excitation is required, it is usual to cover a piece of smooth leather, four or five inches broad, with the amalgam, and apply it with the hand to the revolving disc; and it has been found very useful to apply previously a rag with a little tallow, so as just to give a slight dimness to the glass.

Ronalds' cylinder machine.

Although the plate-glass machine is generally regarded as the best, yet, from its greater cheapness and facility of construction, the cylinder machine is most commonly used. We shall therefore describe at present one of those machines as improved by Mr F. Ronalds.. This machine is represented in fig. 3, where A is a cylinder of blue glass about a quarter of an inch thick, supported by the two mahogany uprights B, B, fixed to the box or case C, which forms the base of the machine. D D is a copper pipe which supports the semicylinder E, which is also hollow, and into which the pipe D opens. This semicylinder carries on its flat side the cushion or rubber, the surface of which is made concave to suit the convexity of the cylinder AA. A small spirit-lamp F, the burner of which consists only of a single cotton thread, is placed, as shown in the figure, immediately beneath the mouth of the copper pipe DD. The prime conductor G, which stands parallel to the cylinder, is a cylindrical tube of thin copper, rounded at both ends, and carrying at its middle a row of metallic points, which nearly touch the surface of the glass cylinder. The conductor G is supported by a hollow glass support H, opening into the hollow conductor G. Its lower end at H is fixed to the wooden case C by means of three screws, one of which is seen at *a* passing through a circular piece of hard boxwood, the inside of which, as well as that of the perforation in the case C, is lined with leather. The lower end of the glass tube H terminates, like that of D, within the case C, and a spirit-lamp is in like manner placed beneath it.

Fig. 3.

By these ingenious contrivances the rubber and the conductor[2] are kept warm and dry, and in damp weather, or in a close room, where the air is rendered moist by the breath of the audience, the machine will be found always effective and in working order. Mr Ronalds is of opinion that the excitation of the cylinder is promoted by the excitation of the amalgam by means of the heat. If similar means are not taken to heat the interior of the glass cylinder, the development of electricity may be promoted by holding a hot piece of cloth or flannel beneath the cylinder while it is in operation.

Ozone or the electrical odour.

In using an electrical machine a singular but not disagreeable odour is invariably felt, which increases with the number of sparks taken from the conductor or from electrical jars and batteries. The same smell is felt when lightning strikes terrestrial objects, and particularly objects in the interior of an apartment. The origin of this remarkable odour has been discovered by M. Schoenbein of Basle, the discoverer of gun cotton, and he has given the name of *ozone* to the substance which produces it. Ozone is highly odoriferous, and is nothing more than oxygen gas possessing a particular chemical activity which it receives from electricity. It has very remarkable properties as a chemical agent which are not possessed by pure oxygen, into which it is converted at a temperature of 300° Centigrade.

SECT. II.—*On the Phenomena of Electrical Attraction and Repulsion.*

Electrical attraction and repulsion.

If the electrical machine, when thus prepared, is put in motion, the two rows of points will collect the electricity which is generated by friction, and the brass conductor CD, fig. 1, will be filled with the electricity thus produced. By means of this electricity the following experiments may be readily performed.

Exp. 1. If we suspend a pith ball by a slender wire, and bring the ball near the conductor, it will be instantly attracted by, and adhere to, the conductor, as long as there is any electricity left. In this case the electricity imparted to the ball by the conductor is carried off by the conducting wire to the hand, and through the body to the earth.

If the pith ball is suspended by a dry silk thread, and held near the conductor, it will at first be attracted to it as formerly; but after it has received as much as it can take, it will then be repelled by the conductor, from the repulsive action of the two similar electricities, and it will not again approach the conductor, till either its own electricity or that of the conductor has been carried off by the contact of some conducting body. In either of these cases the pith ball will be again attracted by the conductor.

Exp. 2. Suspend a little brass ball by a silk thread, and bring the ball near the conductor, so as to receive electricity from it, and be repelled, as in experiment 1. Then with the other hand bring another brass ball near to the first, but on the side of it opposite to the conductor. The first ball will now be attracted to the conductor in conse-

[1] Mosaic gold and the deuto-sulphuret of tin is a good amalgam.

[2] It would be easy to improve this construction by introducing the heated air of other two spirit-lamps into each end of the cylinders.

Phenomena and Laws.

quence of having given out its electricity to the second ball; but having received a new charge of electricity, it will be repelled from the conductor and attracted to the hand or fixed ball. In this way it will oscillate like a pendulum between the conductor and the fixed ball. If in place of the fixed ball we substitute a bell, the ball will oscillate as before, and cause the bell to ring by its successive strokes.

Electrical bells. Plate CCXXII., fig. 4.

Exp. 3. The beautiful experiment of the *electrical bells* is exhibited in fig. 4, where AB is a solid glass rod surmounted by a brass ball A, and supported upon a wooden stand. Two arms of brass crossing at right angles are also supported by the glass rod, and, by means of wires or chains hanging from their extremities, are suspended four bells *b, b, b, b*. From the middle part of each of these cross arms is suspended a brass ball by silk threads, so that each ball when put in motion and made to oscillate in a plane passing through its own cross arm, may strike alternately the middle bell *b'* and the one adjacent to it. If the brass ball is now placed close beneath the brass knob of the prime conductor, or made to communicate with it, the electricity of the conductor will be transmitted through the brass arms to the balls, and the balls giving out their electricity to the bells, will strike them alternately, and cause them to ring, the electricity passing off through the central bell *b'* into the earth.

The experiment may be made more simply by suspending three bells, one from the middle, and one from each extremity of a brass rod, which is hung by its middle part from an electrified conductor. Two brass balls are hung by a silk thread between the central bell and the outer ones. The outer bells are supported by a wire or chain, and the central one by a silk thread. This central bell, however, must communicate with the ground by a chain. When the machine is put in motion, the electricity passes to the outer bells, and the insulated balls, being attracted and repelled, strike the outer bells and the inner one, by which last the electricity passes into the earth.

A still simpler form of the experiment consists in placing two small bells on separate glass stands, at a quarter of an inch distance, one of the bells communicating with the prime conductor, and the other with the ground. A brass ball is then suspended between them by a silk thread, and when the machine is wrought, the electricity will pass to the earth through the bells and the ball, the latter oscillating between them, and ringing them, as long as the current of electricity is kept up.

Exp. 4. Take a dozen of threads about a foot long, and having tied them together at both ends, hang them, by a loop attached to the upper knot, to the prime conductor. When the machine is wrought, the threads will separate from each other, swell out at the middle, and assume a form approaching to that of a sphere. If the threads are merely joined at each end, so that their extremities point to two poles, which may easily be done, they would swell out, and form, as it were, the meridians of a hollow globe. This pretty experiment we owe to Mr Wheler.

Exp. 5. Having fastened a piece of sealing-wax to a wire, and inserted the wire in the hole at the end of the prime conductor, soften the sealing-wax by the flame of a candle, and work the machine;—fine fibres of wax like those of wool will be thrown off, and may be received on paper. By gently heating the paper, the result of the experiment may be fixed. These fibres are thrown off by the repulsion of the electrified particles of wax, which becomes a conductor when melted. The same experiment might no doubt be made with melted sugar, rosin, and other substances.

Exp. 6. The experiment of the dancing figures is one of the finest illustrations of electrical attraction and repulsion. Take two circular discs of wood or pasteboard, E, F, like

Fig. 5.

those shown in fig. 5. Cover them with tinfoil, and having suspended the uppermost from the prime conductor (or from the end D of a metallic rod CD insulated by the glass stand AB, and whose other extremity C communicates by a chain with the prime conductor), place the other upon a stand G, so that, by means of the screw nut *n*, it can be raised or depressed. Place, upon the lower disc small painted figures cut out of paper, and as soon as the machine is wrought the figures will spring upon their feet, and execute the most extraordinary movements, sometimes dancing on their heads, sometimes hanging by the upper plate, and sometimes flying into each other's arms. If these figures are cut out of the pith of the sola tree, and if the arms and legs are made separate, and attached by threads to the body, the effect surpasses all description. The circular discs will answer equally well if made of metal.

Exp. 7. Suspend from the prime conductor a small metallic cup nearly full of water, and having placed in it the shorter end of a syphon made with a capillary glass tube, of such a bore that the water will with difficulty drop from it. When the water is electrified by working the machine, it will be discharged in a continuous stream from the larger arm of the syphon; and if the electricity is powerful, the current of water will divide itself into several branches. In like manner, if a condensed air fountain is electrified, the jet will subdivide itself into minute parts, and suffer great expansion; but the moment the machine stops it resumes its original form. In like manner, if a sponge filled with water discharges the fluid only by drops, it will, when electrified, let fall an abundant shower, which in the dark will be luminous.

Exp. 8. In a metallic cup place a piece of lighted camphor, and when the cup communicates with the electrified conductor, the camphor will throw off numerous ramifications, shooting forth its branches like a vegetable in growth.

An immense number of similar experiments may be made by placing pith balls under inverted tumblers, and thin balls of glass within metallic rings; and when the tumblers and the rings are electrified, the most varied movements are produced; and the effect is greatly heightened by the accompanying luminosity, which displays itself in the dark.

The theory of the phenomena which we have now described will be given in a subsequent section.

SECT. III.—*On the Phenomena of Positive and Negative Electricity.*

Positive and negative electricity.

We have already seen that there are two opposition electricities, which have received the name of *positive* or *vitreous*, and *negative* or *resinous* electricity, the former being generated by excited *glass*, and the latter by excited *wax*.

In order to examine the properties of these two kinds of electricity, take four stands like that shown in page 577, consisting of a vertical rod of glass fixed in a wooden base. From the top of each stand suspend a single pith ball by a slender wire, and place the four stands, which we shall call P, P' and N, N' at some distance from each other on a table. Electrify the pith balls on P, P' by excited glass, so as to make them *positively* electrical; and the pith balls on N, N' with excited wax, so as to make them *negatively* electrical. The following phenomena will then be observed. If the balls P, P' or N, N' are brought near each other, they will *repel* one another, but if P or P' is brought near to N or N', the balls will attract each other. Hence it follows,

Properties of positive and negative electricity.

That two SIMILARLY *electrified bodies P, P' or N, N'* REPEL *each other, while two* DISSIMILARLY *electrified bodies P, N or P', N'* ATTRACT *each other.*

If, in place of electrifying the balls with the glass and the sealing-wax, we had electrified them with the rubber with

Phenomena and Laws.

which they had been excited, we should have found that the rubber which excited the glass gave out *resinous* electricity, and the rubber which excited the wax *vitreous* electricity. Hence we learn,

That in electrical excitation positive and negative electricity are simultaneously produced.

In all electrical machines, therefore, where the plate or cylinder is made of glass, the conductor which takes the electricity from the glass will be charged with *positive* electricity; and as the rubber is negatively electrified, we may obtain negative electricity from it in the same abundance, by placing a conductor behind the rubber, and insulating them both by a glass stand. In the cylinder machine this is easily done, as shown in fig. 6, which represents a machine driven by a wheel and pulley, where E is the negative conductor placed at the back of the rubber R, and S the glass stand by which they are both supported and insulated.

Plate CCXXII., fig. 6.

Van Marum's machine. Plate CCXXIII., figs. 1-5.

In the plate-glass machine it is more difficult to unite a conductor to the rubbers. In Van Marum's beautiful electrical machine, shown in fig. 1–5 of Plate CCXXIII. and which will be more minutely described afterwards, the *positive* and *negative* electricity can be obtained only in succession; but Dr Hare, of the university of Pennsylvania, has removed this difficulty by the very ingenious contrivance shown in fig. 7, of making the plate revolve horizontally, and thus allowing the positive and negative conductors B, F to stand like arches in two vertical planes at right angles to each other.

Dr Hare's machine, Plate CCXXII., fig. 7.

The circumstances of surface and structure under which bodies yield the two opposite electricities by friction are still very imperfectly understood. Mr Canton found that the same body gave out opposite electricities when rubbed with different substances. *Polished glass*, for example, was always *positively* electrified when excited with flannel or silk; but always *negatively* electrified when excited by the back of a cat. But, what was still more strange, he found that *rough glass* acquired *negative* electricity when excited by flannel, and *positive* electricity when excited by dry oiled silk. Rough quartz has been found to exhibit the same difference.

A still more extraordinary and instructive anomaly was observed by Haüy, in exciting a mineral called *kyanite*. Some of the crystals he found to acquire positive electricity by friction, while others acquired negative electricity. Saussure had announced that they were negatively electrified by friction; and when Haüy obtained an opposite result in his first experiment, he was led to examine the subject more carefully, and to make his trials both with the natural faces and with those produced by cleavage. "I have," he remarks, "in my collection a crystal whose opposite faces have presented me with these opposite effects (*electricities*), and I can assign no other cause for this singular result than a certain alteration in the contexture of one of the surfaces." Hence Haüy has given the name of *disthene*, or *two powers*, to this mineral. The remarkable property which Haüy discovered in the individual crystal above referred to may have arisen from some composite structure which he did not recognise.

As the property of giving positive or negative electricity by friction has been used as a mineralogical character, we shall lay before our readers a general view of the experiments which have been made on the subject, which we have collected from a great variety of sources.

Names of the Excited Substances.	Nature of the Electricity produced.	Substances used for Excitation.
Smooth Glass	Positive	Every substance yet tried but the back of a cat and mercury.
	Negative	Back of a cat, and sometimes caoutchouc. (Nich. *Journ.* xxviii. p. 11.)
Rough Glass	Positive	Dry oiled silk, metals, wax, and resinous matters.
	Negative	Woollen cloth, human hand, back of a cat, wood, paper, quills.
Quartz, smooth	Positive	Flannel, &c.
Quartz, rough	Negative	Flannel, &c.
Topaz, smooth	Positive	Flannel, &c.
Topaz, rough	Negative	Flannel, &c.
Back of a living cat	Positive	Every substance yet used.
Hare skin	Positive	Human hand, silk, leather, metals, paper, baked wood, and loadstone.
	Negative	Other finer furs.
White Silk	Positive	Black silk, black cloth, metals.
	Negative	Human hand, weasel's skin, paper, hair.
Black silk	Positive	Sealing-wax.
	Negative	Hare's, weasel's, and ferret's skin, white silk, human hand, brass, silver, iron, loadstone.
Woollen cloth	Positive	Zinc, silver, bismuth, copper, lead, oligist iron.
	Negative	Platina, gold, tin, antimony, grey copper, grey cobalt, tellurium, &c.
Sealing-wax	Positive	Rough glass, white wax, sulphur, and all metals except iron, steel, plumbago, lead, and bismuth.
	Negative	Hare's, weasel's, and ferret's skin, human hand, leather, smooth glass, flannel, wood, paper, iron, steel, plumbago, lead, and bismuth.
Baked wood	Positive	Silk, paper, rough glass, wax, lead, sulphur, and the metals.
	Negative	Flannel, hare's skin, smooth glass, quills.
Sulphur	Positive	All metals but lead.
	Negative	Lead and all other substances.
Resinous bodies	Positive	All resinous substances.
	Negative	All bodies but resinous ones.

Electricity of minerals.

The most accurate and numerous observations on the development of electricity by friction were made by the Abbé Haüy in reference to the discovery of new characters of minerals. He rubbed the minerals on a woollen cloth, and when it was necessary to insulate them, he fixed them by wax to the end of a stick of gum-lac or Spanish wax. In this way he divided the mineral kingdom into four classes of bodies in reference to the electrical character of the minerals.

Class. I.—*Containing minerals which possess the insulating property,*[1] *and acquire vitreous electricity by friction.*

Boracite.	Carbonate of lime.
Topaz.	Carbonate of magnesia.
Axinite.	Arragonite.
Tourmaline.	Apatite.
Mesotype.	Fluate of lime.
Prehnite.	Gypsum.
Oxide of zinc.	Anhydrite.
Sphène.	Sulphate of barytes.

[1] That is, that they do not require to be insulated or placed upon a substance which does not conduct or carry off electricity, in order to exhibit their electricity.

Phenomena and Laws.

Sulphate of strontian.	Feldspar.
Carbonate of barytes.	Apophyllites.
Carbonate of strontian.	Actinote.
Sulphate of magnesia.	Tremolite.
Siliceous borate of lime.	Diopside.
Nitrate of potash.	Epidote.
Sulphate of potash.	Stilbite.
Muriate of soda.	Analcime.
Glauberite.	Nepheline.
Hyalin quartz.	Kyanite.
Zircon.	Mica.
Corundum.	Macle.
Cymophane.	Talc transp.
Spinelle.	Diamond.
Emerald.	Carbonate of lead.
Euclase.	Sulphate of lead.
Cordierite.	Tungstate of lead.
Garnet.	Carbonate of zinc.
Essonite.	Oxide of tin.
Idocrase.	

CLASS II.—*Containing minerals which possess the insulating property (excepting anthracite), and acquire resinous electricity by friction.*

Sulphur.	Amber.
Bitumen.	Mellite.
Retinasphaltum.	Anthracite.

CLASS III.—*Containing conducting substances which acquire, when they are insulated and rubbed, the one order vitreous electricity, and the other resinous electricity.*

Order 1. Substances which acquire vitreous electricity.

Pure silver.	Copper coin.
Native silver.	Pure zinc.
Silver coin.	Brass.
Pure lead.	Native bismuth.
Pure copper.	Native amalgam.
Native copper.	

Order 2. Substances which acquire resinous electricity.

Pure platina.	Sulphuret of lead.
Native platina.	Copper pyrites.
Palladium.	Grey copper.
Pure gold.	Sulphuret of copper.
Native gold.	Graphite.
Gold coin.	Common sulphuret of iron.
Pure nickel.	White sulphuret of iron.
Native iron.	Magnetic sulphuret of iron.
Hammered iron.	Sulphuret of tin.
Pure tin.	Sulphuret of bismuth.
Amalgam of tin and mercury.	Sulphuret of manganese.
Native arsenic.	Sulphuret of antimony.
Pure antimony.	Sulphuret of molybdena.
Native antimony.	Chromate of iron.
Tellurium of Naygag.	Oxide of iron.
Antimonial silver.	Jenite.
Arsenical nickel.	Black oxide of cobalt.
Arsenical iron.	Oxidulated uranium.
Oxidulated iron.	Wolfram.
Metalloidal oxide of manganese.	Tantalite.
	Yttro-tantalite.
Sulphuret of silver.	Black oxide of cerium.

CLASS IV.—*Containing Substances which acquire resinous electricity by friction. The insulating property is limited to the very transparent varieties.*

Ruby silver.	Arseniate of copper.
Sulphuret of mercury.	Dioptase.
Red copper ore.	Phosphate of copper.
Oligist iron ore.	Hydrate of copper.
Sulphuret of arsenic.	Sulphate of copper.
Titanite.	Phosphate of iron.
Anatase.	Arseniate of iron.
Muriate of mercury.	Sulphate of iron.
Chromate of lead.	Sulphuret of zinc.
Phosphate of lead.	Red cobalt.
Molybdate of lead.	Green oxide of uranium.
Green carbonate of copper.[1]	White oxide of antimony.
Blue carbonate of copper.	Red oxide of cerium.

As the causes which determine the production of positive or negative electricity by friction are wholly unknown, and require to be carefully investigated, we must warn the philosopher against the implicit adoption of all the preceding determinations. Different results have in many cases been obtained by different observers, and even by the same observer while using the same materials; and we could have greatly enlarged the first of the preceding tables had we inserted the opposite results of different observers. There are two points, however, which require to be attended to in such inquiries: *1st*, There is a tendency to the production of negative electricity in the substance which has the least extent of surface; and, *2dly*, there is a tendency to the production of an opposite electricity when the surface of the body is even minutely scratched.

Faraday's Experiments.

Besides the chemical nature of the bodies, the kind of electricity produced by friction depends on various physical circumstances in the two bodies. Polish, for example, tends to produce vitreous, and heat resinous electricity. Mr Faraday obtained interesting results by rubbing together the substances in the following table in pairs.

1. Calfskin and Bearskin.	9. White Silk.
2. Flannel.	10. The hand.
3. Ivory.	11. Wood.
4. Quill.	12. Lac.
5. Rock crystal.	13. Metals—Iron, copper, brass, tin, silver, platinum.
6. Flint Glass.	14. Sulphur.
7. Cotton.	
8. Linen, Canvas.	

If any one of these substances is rubbed against the substance *above* it, it becomes *negatively* electrified, and if against the substance *below* it, the electricity is *positive*. Mr Faraday, however, found many exceptions to this rule. One part of a cat's skin, for example, was very negative to another part, and even to rock crystal, and different pieces of flannel also differed much from each other; a change in the mode of rubbing, too, made a great difference. A feather struck lightly against a dry canvas becomes strongly negative, while the same feather drawn with a little pressure between the folds of the same canvas will be strongly positive. When a piece of flannel is halved, and the two pieces drawn across each other, the electricity of the two will be of a different kind irregularly; or the same piece will have both electricities in different parts; or, sometimes, both pieces will be negative, in which case Mr Faraday thinks that the air must have been rendered positive and then dissipated.

When we come to describe the hydro-electric machine, we shall find that water is positive when carried through tubes of wood and metal by a stream of steam, the tubes becoming positive; and Mr Faraday thinks it will probably be found to stand above all other substances, even cats' hair and oxalate of lime.

Mr Wilson had found that a stream of air directed against a tourmaline, or glass, or resin, electrified these substances positively; but Mr Faraday has shown that no electrical effect is produced unless the air is damp, or holds dry powders in suspension. In these cases, the electricity is produced by the friction of the particles of water in the one case, and the particles of powder in the other.

In order to account for the production of electricity by friction, Dr Wollaston ascribed it to an oxidation; but this cannot be the cause of it, as electricity is produced by friction in vacuo, as was shown long ago by Stephen Gray; and what is a still more decisive objection to this theory, Gay Lussac found that electricity could be developed by friction in dry carbonic acid.

SECT. IV.—*On Electrical Conduction.*

Electrical conduction.

It is obvious, from all the phenomena described in the preceding sections, that electricity is communicated from

[1] This salt has often the insulating property, and acquires vitreous electricity by friction.

Phenomena and Laws.

one body to another. The excited glass or wax communicate, as we have seen, their electricity to a pith ball; and the electricity of the machine is conveyed first to the prime conductor, and from that to the bells or other apparatus which have been already described. If we touch an electrified pith ball, or any other electrified body, with a rod of metal of any kind, the electricity of the pith ball will be instantly carried off; but if we touch it with glass or wax it will not be carried off. Hence metals are said to be *conductors*, and glass and wax *non-conductors*, of electricity.

Bodies vary greatly in the degree in which they conduct electricity; and many of them owe their conducting power to the water which they contain. The conducting power of any substance depends on the state of the atmosphere at the time with regard to humidity, and on the intensity of the electricity employed. The following tables of conductors and non-conductors have been collected from different authors. The bodies are placed in the order of their conducting or non-conducting power; but it is probable that this order would be greatly changed if the bodies were all submitted to a new and uniform examination.

List of Conductors.

All metals.	River water.
Silver.	Ice above − 13° Fahr.
Copper.	Snow.
Lead.	Living vegetables.
Gold.	Living animals.
Brass.	Flame.
Zinc.	Smoke.
Tin.	Steam.
Platina.	Soluble salts.
Palladium. }	Rarefied air.
Iron heated. }	Vapour of alcohol.
Iron cold. }	Vapour of ether.
Charcoal well burned.	Moist earths and rocks.

	Gun cotton.[2]

Insulators.

The most perfect *non-conductors* of electricity are also called *insulators*, from their power of insulating an electrified body, or preventing any of its electricity from escaping along its support. It is to Coulomb that we owe the useful discovery that *shell-lac* is the most perfect of all insulators; and hence it is of great value in electrical inquiries. Coulomb found that the electricity of a pith ball five or six lines in diameter could be completely insulated by a cylinder of sealing-wax or gum-lac about half a line in diameter, and eighteen or twenty lines long; that a very fine silk thread, penetrated and covered with melted wax so as to form a cylinder one-fourth of a line in diameter, had the same insulating power when its length was five or six inches; and that an equal degree of insulation could not be obtained by a fine thread of glass five or six inches long, or by a hair or a fibre of silk, unless the electricity insulated was very weak, or the air very dry. Coulomb found also that the density of electricity insulated by a fibre of gum-lac was ten times as great as that which could be insulated by a silk fibre of the same length and diameter; and he established the following general law, *that the densities of electricity insulated by different lengths of fine cylindrical fibres, such as those of gum-lac, hair, silk, &c., vary as the square root of the lengths of the fibre.*

Conduction of positive and negative electricity.

In examining whether or not positive and negative electricity were conveyed with equal facility by conducting bodies, M. Erman found that there were some bodies which completely obstructed the passage of one kind of electricity, while they afforded a ready passage to the other. As this result, however, was obtained by weak galvanic electricity, the question is still open to examination in reference to ordinary electricity.

Although some bodies are said to be perfect non-conductors, yet this is not strictly true. A strong electrical charge can be made to pass through a thin film of the worst conductor. Dr Ritchie found that electricity permeated thin balls of blown glass; and though in one case he found that a small invisible aperture had been made in the glass, yet in other experiments he could not by any known method detect the smallest perforation.

Influence of heat in promoting conduction.

It has been long known that imperfect conductors have their conducting power increased by heat; gases, charcoal, glass, ice, and resins when melted, are proofs of this. Dr Ritchie,[3] on the authority of some accurate experiments, is of opinion, that if the body be naturally a pretty good conductor, the ratio of its conducting power will not be so much increased by heat as in the case of a less perfect conductor. Marianini found this to be true with fluid conductors, and Dr Ritchie thinks that it is universally true.

Plate CCXXVII., figs. 1 & 2.

An interesting paper on this subject by Sir Snow Harris, will be found in the *Edinburgh Transactions* for 1832; in which the author describes a new electrometer, and measures the degree of heat excited in metallic bodies by voltaic electricity. The results of his inquiries are—"That for certain given small forces the differences in the conducting powers of the several metals vanish, each metal being equally efficient. 2d. That differences in conducting power become more apparent within a certain limit, as the

[1] Glass of soda is the best conductor, and glass of potash the worst. M. Mathiessen found a species of glass which was absolutely incapable of receiving any electric charge, and he found it to be a glass of soda almost entirely free of potash. The conducting power of glass increases with its temperature. M. Buff has found from very accurate experiments that the glass of tubes used for chemical experiments, which is a good insulator, had its insulating power increased by heat nearly as in the following table:

Temp. Cent.	Insulating power.	Temp. Cent.	Insulating power.
200°	2582	350°	12
250	158	400	8
300	17		

[2] When made in large quantities this substance preserves the form of the sheet of cotton-wool from which it is made. When it is well dried a cloud of sparks will be produced by drawing it through the hand.

Phenomena and Laws.

Influence of heat in promoting conduction.

force of the battery increases:" the exact proportions in which the differences increase with the increased power the author had not accurately ascertained. In reasoning on the several experimental results arrived at, our author traces the source of these phenomena to certain unknown relations subsisting between the causes of heat and electricity, and is led to adopt the principle advocated by Sir H. Davy, that the excitation of heat in the metal diminishes its conducting power. He found by several striking experiments that the electrometer became most sensibly affected by changes of temperature in the wire transmitting the charge, and that whether by the common means of heat or cold directly applied to it, or otherwise by means of an electrical current; so that it does not appear to be of any consequence how the heat is derived by which the conducting power is diminished. Hence it follows that the heat excited in a metallic body during the time of its conduction would tend to impede the transmission of the electrical current. In certain cases, therefore, of electricity of low tension, the heat excited in different metals may be so small as not to interfere with the transmission of the current, and they may all appear to conduct equally well in that particular case. With respect to currents differing in intensity, he found that when the force was very considerable, the best conductor became the most heated, from the circumstance of its permitting a larger quantity of electricity to pass through it. When the force of the battery became less, then the inferior conductor became the most heated; because it is now capable of transmitting the whole current.

There is however a contingency attendant on experiments of this kind, which, as observed by Sir Snow Harris in his inquiries into the Elementary Laws of Electricity,[1] demands very especial attention. The author has shown, in the course of these investigations, that rarefied air does not restrain the electrical discharge to the same extent as dense air. He found that a given accumulation on coated glass would strike through twice the distance in air of half the density; and, further, that an electrical accumulation was transmitted with much greater facility over a wire when the atmospheric pressure was removed from its surface; so much so, that an extremely fine steel wire became beautifully luminous in a closely exhausted receiver, in transmitting without fusion a powerful accumulation which in the atmosphere would dissipate the metal in red-hot balls. When an electrical discharge therefore is caused to pass over a heated surface in the atmosphere, as for example, that of iron heated to redness, we have to take into the account the necessarily rarefied state of the air in contact with the metal, and which may permit a free passage along its surface, thereby more than compensating for any diminished power of conduction in the metal itself. Unless therefore such experiments be conducted in a space devoid of air, or nearly so, they can not be well received in opposition to a large class of well established facts, and must be always more or less inconclusive.

A question arises here, bearing on the relations between heat and electricity, of no small interest to these branches of physical science. Is the source of heat material, and if a material element, is heat a conductor or insulator of ordinary electrical action? The following are some singularly interesting experiments relative to this question, by Sir Snow Harris, communicated to the Royal Society in 1834.[2] Having examined the laws of electrical discharge of high tension in air varying in density, and having fully shown that the resistance of the atmosphere to the passage of free electricity is not greater through one discharging distance than through another, and in no case greater than the existing atmospheric pressure; he proceeds to examine the influence of an atmosphere of variable density and temperature in arresting the progress of electrical discharge; and he finds, 1. That the quantity requisite to force a given interval, varies in a simple ratio of the density, so that when the density was only one-half as great, the discharge occurred with one-half the quantity accumulated. 2. That the distance through which a given accumulation could discharge was in a simple inverse ratio of the density. Thus, as already observed, in air of half the density the discharge from a given accumulation occurred at twice the distance. Having determined this, the author endeavours to find whether the influence of heat was such as to impair or augment the insulating power of the air, which he does by forcibly retaining a given volume of air within a glass receiver, and causing given electrical accumulations to discharge through it, under very considerable variations of its temperature, viz., from 50 to 300 degrees of Fahrenheit.

Apparatus used by Sir Snow Harris.

The manipulation and apparatus by which all these experiments were effected may be thus briefly explained:—Two smooth balls of brass of about an inch and a half in diameter were directly opposed to each other within a large glass receiver connected with an effective air-pump. These balls could be set at given measured distances between their nearest points, by means of a sliding brass rod passing through an air-tight collar and glass plate on the top of the receiver acted on by a micrometer screw and index. The air-pump was fitted with a long mercurial gage and a delicate Fahrenheit thermometer placed within the receiver. Given quantities of electricity, measured by the unit jar (Plate CCXXIX., fig. 17), were accumulated on coated glass, the thermo-electrometer (Plate CCXXVII., figs. 1 and 2) for measuring the effect of the discharge occasionally placed in the circuit, and discharges caused to pass between the brass balls within the receiver under a variety of different circumstances. The temperature of the air contained within the receiver was raised at pleasure, by means of an external metallic envelope and a lamp, so contrived as to be removed at pleasure without disturbing the fixed pieces, which, under the ordinary pressure of the atmosphere without, resisted the expansive power of the air contained within the receiver, when the volume was required to be the same under different temperatures, and at the density of the external air.

Plate CCXXVII., figs. 1 & 2.

As a preliminary experiment, a given quantity of electricity was accumulated and discharged between the brass balls within the receiver in air of constant temperature, but varying in density. By diminishing the density, the distance of discharge within the receiver could be extremely increased. The results of thirty successive experiments give an invariable effect on the wire of the thermo-electrometer, at whatever distance the discharge passed between the brass balls; showing that the resistance to the passing shock must have been in each case alike. In order to effect discharges between the balls in the receiver within the limit at which the accumulated electricity could force a passage, the battery was discharged externally to the receiver by a drop ball falling with force on a small plate of varnished glass resting on an opposed ball, in connection with the positive coating; thus impeding the discharge of the battery up to a given instant. The experiments being now arranged solely with reference to heat, an accumulated quantity was effected adequate to discharge over a certain distance between the balls in the receiver, in a volume of air of a noted temperature. This being determined, and the volume fixed by closing the stop-stock connected with the receiver, the temperature within was varied from 50° to 300° of Fahrenheit, but without in any way affecting the result. The discharge of the battery invariably occurred when the same quantity had accumulated, or very nearly. The experiments were sufficiently approximative to show that the heat had in no degree affected the restraining or insulating power of the air.

[1] *Phil. Trans.* for 1834, p. 230.

[2] On some Elementary Laws of Electricity, First Series.

Phenomena and Laws.

The heated air was now permitted to expand, by opening the stop-cock under the receiver, and allowing an escape through the long mercurial gage from beneath the surface of the mercury below. When full expansion had taken place, the cock was again closed. This done, the quantity of accumulated charge in the battery now requisite to pass between the balls in the receiver was again determined, which, although necessarily reduced, was found still constant through all succeeding depressions of the temperature, from 280° down to the temperature of the external air. When this was reached, the cock was again opened so as to allow the mercury to rise in the gage, by which the final density could be pretty well ascertained. The comparative quantitative accumulations were then found to be as the diminished density, or very nearly so.

The author describes several other forms of these experiments on the power of heated air to restrain electrical discharges, but the results were found the same. The insulating power of the air was found quite independent of the temperature, and to have reference only to the condition of density.

The author thinks that we may fairly conclude from these experiments—

1. That heated air is not, as frequently stated, a conductor of electricity; and that heat in no way facilitates electrical discharge through air, except by affecting its density.

2. Supposing the cause of heat to be a material element, it must necessarily be an electric or non-conductor; because the incorporation of a conducting with a non-conducting substance is always found to impair its insulating property—as for example in the case of air charged with free vapour; whereas in the intimate union of two non-conductors the insulating power is in no way impaired. Since, then, heat does not impair the insulating property of a given volume of air, heat, if a substance, should therefore be an electric, and have insulating properties.

The converse of this reasoning furnishes additional evidence of this. It is a well-known fact, as we shall hereafter find, that the excitation of heat in good conductors, such as the metals, greatly impairs their conductibility; a result invariably attendant on the mixture of a conducting with an insulating substance, and even evinced on amalgamating a good conducting metal with a metal low in the scale of conducting power.

Experiments of Delarive.

It appears from some recent experiments made by Professor Delarive of Geneva, that the degree of conductibility of bodies for electricity *depends on the quantity of electricity which traverses them.* Hence it follows, that, of two conducting bodies, that which is the most perfect for an electric current of a given intensity may be the worst conductor for either a stronger or a weaker current. The conducting powers of bodies, therefore, ought to be re-examined in reference to electric currents of different intensities; and when such experiments are made with accuracy, we may expect that they will lead to great improvements in our electrical apparatus.

Dr Faraday's new law of conduction.

Much light has been recently thrown on the conducting power of bodies by the researches of Dr Faraday, of which we have already given a general account in our history of electricity. He found that a great number of solid bodies which were incapable of conducting electricity of low tension, acquired by liquefaction or fusion the power of conducting it in a very high degree. The following is a list of the bodies which possessed this property:

Water.

Oxides. Potassa, protoxide of lead, glass of antimony, protoxide of antimony, oxide of bismuth.

Chlorides of potassium, sodium, barium, strontium, magnesium, manganese, zinc, copper (proto-), lead, tin (proto-), antimony, silver.

Iodides of potassium, zinc, and lead; protiodide of tin, periodide of mercury, fluoride of potassium, cyanide of potassium, sulpho-cyanide of potassium.

Salts. Chlorate of potassa; nitrates of potassa, soda, baryta, strontia, lead, copper, and silver; sulphates of soda and lead; proto-sulphate of mercury; phosphates of potassa, soda, lead, copper, phosphoric glass, or acid phosphate of lime; carbonates of potassa and soda, mingled and separate; borax, borate of lead, perborate of tin; chromate of potassa, bichromate of potassa; chromate of lead; acetate of potassa.

Sulphurets. Sulphuret of antimony, sulphuret of potassium made by reducing sulphate of potassa by hydrogen, ordinary sulphate of potassa.

Silicated potassa; chameleon mineral.

In those substances which soften before they liquefy, Dr Faraday found it highly interesting to watch the increase of conducting power as they approached to perfect fluidity. When borate of lead, for example, is heated by the lamp upon glass, it becomes as soft as treacle, without gaining the power of conduction; and it was only when brought to a fair red heat by the blowpipe that it conducted. When it was quite liquid, it conducted with extreme facility.

The following bodies were found by Dr Faraday to acquire no conducting power when they assumed the liquid state.

Sulphur.	Adipocire.
Phosphorus.	Stearine of cocoa-nut oil.
Iodide of sulphur.	Spermaceti.
Periodide of tin.	Camphor.
Orpiment.	Naphthaline.
Realgar.	Resin.
Glacial acetic acid.	Gum sandarach.
Mixed margaric and oleic acids.	Shell-lac.
	Perchloride of tin.
Artificial camphor.	Chloride of arsenic.
Cafeine.	Hydrated do.
Sugar.	

Boracic acid and green bottle glass raised to the highest heat by an oxyhydrogen flame acquired no conducting power. Flint glass conducted a little when so heated.

When a solid becomes fluid it loses almost wholly its power of conducting heat, and gains in a high degree that of conducting electricity, and *vice versa;* and hence Dr Faraday concludes that there is a natural dependence between the two classes of facts.

Dr Faraday concludes his very interesting researches on this subject with the following summary of conditions of conduction in bodies, which, though they apply chiefly to voltaic electricity, are yet true within certain limits for ordinary electricity.

Conditions of electrical conduction.

1. All bodies conduct electricity in the same manner, from metals to lac and gases, but in different degrees.

2. Conducting power is in some bodies powerfully increased by heat, and in others diminished, yet without our perceiving any accompanying essential electrical difference, either in the bodies or in the changes occasioned by the electricity conducted.

3. A number of bodies insulating electricity of low intensity when solid, conduct it very freely when fluid, and are then decomposed by it.

4. There are many fluid bodies which do not sensibly conduct electricity of this low intensity; there are some which conduct it and are not decomposed, nor is fluidity essential to decomposition.

5. There is but one body yet discovered (periodide of mercury) which, insulating a voltaic current when solid, and conducting it when fluid, is not decomposed in the latter case.

6. There is no strict electrical distinction of conductors which can as yet be drawn between bodies supposed to be elementary and those known to be compounds.

The experiments of Dr Faraday with ice, in which it

Phenomena and Laws.

appeared that electricity of exalted intensity passed through it, while it completely stopped voltaic electricity, confirms the observations of M. Delarive on the relation between the conducting power and the quantity of electricity which traverses the conductor; and the phenomena seem to indicate that the electric fluid or matter may consist, like solar light, of different parts possessing different powers of conductibility and other properties, which may facilitate or obstruct their passage through solid, fluid, or gaseous bodies. An electric current, composed of different currents, may have some of its component currents entirely stopped by some bodies, while other currents are transmitted with the greatest facility, in the same way as certain rays both of light and heat are entirely absorbed by coloured bodies, while other rays are copiously transmitted. Non-conductors, like black bodies, stop every electrical current. Perfect conductors, like colourless transparent bodies, may transmit every electrical current, or absorb a small portion of all of them in an equal degree; while there may be imperfect conductors, which, like coloured bodies, stop some currents and transmit others. If this should prove correct, two bodies which, when used separately, conduct electricity, would be insulators when joined so as to transmit the electricity in succession, in the same manner as two transparent coloured bodies which separately transmit light copiously are opaque when combined, the light which each transmits being absorbed by the other.

Absorption of electricity.

Distance to which electricity has been conducted;

We have already seen that electricity was conveyed through a distance of four miles. On the ground that these experiments were made imperfectly, and that an electric charge will prefer a short passage through air to a passage of twenty or thirty feet through thin wire, Mr Singers has expressed his conviction that the results of the experiments referred to are incorrect. We are unable, we confess, to appreciate the reasons on which this opinion is founded; but, even if they have any force, the original fact has been more than confirmed by Mr F. Ronalds, who erected at Hammersmith an electrical telegraph on which the inflections of the wire composed *one continuous length of more than* EIGHT *miles*. "When a Canton's pith-ball electrometer was connected with each extremity of this wire, and it was charged by a Leyden jar, both electrometers appeared to diverge suddenly at the same moment; and when the wire was discharged by being touched with the hand, both electrometers appeared to collapse as suddenly. When any person took a shock through the whole length of wire, and the shock was compelled to pass also through two insulated inflammable air pistols, one connected with each extremity of the wire, *the shock and the explosion seemed to occur simultaneously*. But when the shock was compelled to pass through the gas pistols, and any one closed his eyes, it was *impossible* to distinguish more than one explosion, although both pistols were discharged. When people did not look at the pistols, and when I sometimes charged only one highly, and sometimes both lowly, they could never guess, except by mere chance, whether one or both were fired. *Thus, then, three of the senses, namely, sight, feeling, and hearing, seemed to receive absolute conviction of the instantaneous transmission of electrical signs through my pistols, my* EIGHT *miles of wire, and my own proper person*."[1]

through telegraphic wires and submarine cable.

These results, interesting as they were some years ago, sink into insignificance compared with the extraordinary facts with which the operations of the electric telegraph have made us acquainted. The transmission of electricity through hundreds of miles of wire passing through the atmosphere, and through 300 miles of submarine wires stretching from Dover to Ostend, are facts familiar to everybody. Experiments have not yet been made to ascertain the distance to which a given electric force will pass through wires of different lengths and diameters, when insulated and uninsulated; but from the opportunities which we now possess from the extension of the telegraphic system, we may expect that very interesting results will ere long be obtained. The completion of the electric current, too, through immense distances in the ground and in water—as first noticed through distances of a few miles by Sir William Watson—is a remarkable fact which requires farther investigation in reference to Mr Lindsay's proposal of a transmarine telegraph.[2]

Velocity of electricity.

Various attempts have been made to measure or rather to estimate the velocity of electricity in passing along a conducting wire. Sir William Watson considered it to be less than any measurable portion of time in passing through a distance of 12,276 feet or 2¼ miles, or as he expressed it, that it passed instantaneously through such a length of wire. The first attempt to measure the velocity of electricity by any accurate method, was made by Mr Wheatstone, who, by an ingenious apparatus, concluded that it moved along a copper wire at the rate of 288,000 miles in a second. According to the experiments of MM. Fizeau and Gonelli, it moves through a similar wire at the rate of 112,680 miles per second, and through an iron wire at the rate of only 62,000 miles. Professor Mitchell of Cincinnati found its velocity to be only 28,500 miles in a second; and Professor Walker of the United States only 16,000 miles through an iron wire. Along the copper wire between Greenwich and Edinburgh, its velocity was only about 6500 miles per second; and along the copper wire (a great part of which was plunged in water), between Greenwich and Brussels, only 2300 miles in a second. Dr Faraday ascribes the enormous differences in these measures, to a certain extent, to the influence of the conducting bodies in contact with the wire; and he is of opinion that the velocity may vary more than the hundredth of its velocity according as the electricity passes through a wire immersed in water, or through one suspended at a great distance from the ground, or one carried along a solid conducting wall. These experiments on the electric telegraph wires confirm, in a remarkable degree, the sagacious anticipation of Dr Faraday, who announced, at the time of the publication of Wheatstone's experiments, that *the velocity of electricity in the same metallic* would vary much "with the tension or intensity of the first urging force, which tension is charge and induction. So if the two ends of the wire in Professor Wheatstone's experiment were immediately connected with two large insulated metallic surfaces exposed to the air, so that the primary act of induction, after making the contact for discharge, might be in part removed from the internal portion of the wire at the first instant, and disposed for the moment on its surface, jointly with the air and the surrounding conductors, then I venture to anticipate that the middle part would be more retarded than before; and if these two plates were the inner and the outer coating of a large jar or a Leyden battery, then the retardation of that spark would be still greater."[3]

Experiments of Faraday.

These interesting anticipations have been proved by a series of fine experiments made by Dr Faraday with the telegraphic lines of wire between London and Manchester. This wire, which is 1400 miles long, is buried in the ground, and consists of four wires, each 350 miles long. At the Manchester station the extremities of the first and second wire were united, and also the extremities of the third and fourth. At the London station a galvanometer was attached to the end of the first wire, the ends of the second and third wire were united by a second galvanometer, and at the end of the fourth wire was attached a third galvanometer commu-

Phenomena and Laws.

nicating with the ground. The first galvanometer was then put in connection with one of the poles of a pile, the other pole of which communicated with the ground. The needle of the first galvanometer immediately deviated, but that of the second did not move till after a sensible interval, and that of the third a little later still. About two seconds elapsed before the electric current was propagated from the first to the third galvanometer. Upon cutting off the communication between the first galvanometer and the pile, the needle of the first galvanometer immediately returned to zero, that of the second was not displaced till after a short time, and that of the third still later. By establishing or cutting off the communication between the first galvanometer and the pile, at intervals not very distant, we may in some degree project along the wire successive electric waves, so that the three galvanometers are traversed at the same instant with three different waves. Finally, if after cutting off the communication between the pile and the first galvanometer, we connect this galvanometer with the ground, the electricity with which the wire is charged will discharge itself simultaneously by its two extremities, so that the first and the third galvanometer are traversed by electric currents in opposite directions. With a telegraph wire suspended in the air, the three galvanometers deviate from and return to zero almost exactly at the same instant.

Dr Faraday on the velocity of electricity.

Mr Bain's telegraph.

Similar results were obtained by Dr Faraday by the beautiful experiment of using three of Bain's telegraphic apparatuses, in which messages are written chemically by lines or strokes of different lengths. When the circuit was interrupted, as before, at intervals not very distant, the apparatus nearest the pile traced a discontinuous line, composed of full and distinctly separated strokes, thus, — - — — produced during the intervals when there was a communication with the pile. The second and third apparatus, on the contrary, gave a line composed of full and distinct strokes united by very delicate ones, thus, ———————; which showed that the electricity took a certain time to escape from the wire. When the interruptions of the current are very near one another, the fine lines become equal to the full ones, and a continuous line ——————— is produced.

Sect. V.—*On the Electric Spark.*

Electric spark.

Since the discovery of electric light by Otto Guericke and Dr Wall, the subject has attracted the particular attention of philosophers. In exciting a glass tube, or in working an electrical machine in the dark, sparks and streams of light are distinctly visible; but the phenomenon is best seen when the knuckle or a brass ball is brought near to an electrified conductor. A bright light, called the *electric spark*, passes from the conductor to the knuckle or ball, and exhibits a great variety of phenomena, varying with the nature and intensity of the electricity, and with the form, magnitude, distance, and nature of the bodies between which it passes.

The electric spark is produced by the action of the positive electricity in the conductor, upon the neutral electricity in the knuckle or ball that receives the spark, the former decomposing the latter. When the attraction between the two electricities is sufficiently powerful to overcome the resistance of the air, the two fluids on the knuckle recombine with a noise, accompanied by a brilliant spark like the forked lightning in a thunderstorm. This mode of discharging the electricity of conductors is called the *disruptive discharge*, and the distance of the bodies between which it is made is called the *striking distance*.

Form of the spark.

Exp. 1. Having screwed into the prime conductor a brass ball about two inches in diameter, and projecting about three inches, electrify the conductor positively, and hold another ball near the first. Long ramified zigzag sparks will pass between the two balls, as shown in fig. 6, where *pos.* is the *positively* electrified ball, and *nat.* the one held in the hand in a natural state of electricity. If the ball on the conductor is very small, the spark will become a faint divided brush of light. If the ball on the conductor is electrified negatively, the spark will be as shown in fig. 7, clear, straight, and more luminous. If one of the balls is *positively*, and the other *negatively* electrified, the forms shown in fig. 6 and 7 will be combined, as in fig. 8. When, in this last experiment, the distance of the balls is not too great, the positive zigzag spark will strike the negative straight spark about one-third of the length of the latter from its point, the other two-thirds becoming very luminous. Sometimes the positive spark strikes the negative ball at a distance from the negative spark.

Plate CCXXIII., figs. 6, 7, 8.

Exp. 2. If two conductors P, M, fig. 9, three-fourths of an inch in diameter, and having spherical ends, are placed parallel to each other, at the distance of two inches, so as to have their ends pointing in different directions six or eight inches asunder; then, if P is positively electrified, its spark will strike the other conductor M in its natural state, as in fig. 9. If M is electrified negatively, and P connected with the earth, the conductor M will send the negative spark to P, as in fig. 10; and if the conductors have opposite electricities, the positive spark will appear at one end, and the negative at the other, as shown in fig. 11.

Fig. 9.

Fig. 10, 11.

Exp. 3. Upon the brass stem *bc*, fig. 12, having a fine point at *c*, place a brass ball A, about three inches radius, so that the point *c* can be protruded to any distance beyond the ball, or be drawn within it, as shown in the figure. In this last state the point produces no effect and the zigzag spark appears between the balls.

Fig. 12.

In proportion, however, as the point is protruded, its transmitting power is increased, and it may be made to have the same effect as any ball, from the smallest size to one three inches radius. When the point projects to a particular distance, it acts as if no ball were present.

Exp. 4. Hold an insulated sheet of paper at a small distance from a *positively* electrified conductor, and a beautiful star with distinct radiations will be thrown upon the paper. If the conductor is *negatively* electrical, a cone of rays, with its base on the paper and its apex on the conductor, will replace the star.

Exp. 5. If the point of a needle is presented to a positively electrified conductor in the dark, the point will be illuminated with a star; but if the conductor is *negative*, the needle will exhibit a pencil or brush of light.

The following experiment illustrates the effect of distance on the spark.

Exp. 6. Fix a sharp-pointed wire to the end of the prime conductor, and having electrified it positively, hold an uninsulated ball of metal very near the metallic point; a succession of small and *brilliantly white* sparks will pass between them. The white colour will tend to red as the distance of the ball and the point is increased, and at a certain distance the sharp explosions will cease, and a feeble violet light will diverge from the extremity of the point, covering with its base the nearest half of the sphere.

Influence of distance on the spark.

The influence of the form of the body upon the spark which it gives is considerable. Professor Hildebrand of Erlang found that an obtuse cone with an angle of 52° gave a much more luminous spark than one with an angle of 36°, and he found that the parabolic rounding of the summit, or slight inequalities of surface, are particularly advantageous in the production of a strong light. The influence of points on the spark has been already described.

Influence of form on the spark.

The nature of the body by which the spark is taken exercises also an influence upon its magnitude and its colour. Professor Hildebrand made some interesting experiments on this subject. The pieces of metal had a

Influence of substance on the spark.

Phenomena and Laws.

conical form, and of the same shape and size. When they were fixed in the same manner at the end of an insulated conductor, the sparks which they yielded differed much in extent. The following table exhibits the results of these experiments, the metals at the head giving the greatest sparks.

Regulus of antimony.	Sulphuret of copper.	Lead.
Gold.	Tin.	Steel.
Silver.	Zinc.	Tempered steel.
Brass.	Iron.	

When the spark is *white* by taking it with a metallic body, it will under the same circumstances be *violet* if taken with the finger. If the spark is taken with ice or water, or a green plant, its light will be red; and if it is taken with an imperfect conductor, such as wood, the light will be emitted in faint red streams.

Influence of the medium on the spark;

The medium through which the spark is transmitted exercises also a remarkable influence on its colour and form. A spark capable of passing through only half an inch in common air, will pervade six inches of the Torricellian vacuum. The apparatus used by Sir H. Davy for examining the influence of a vacuum, &c. is shown in fig. 13, where ABC is a bent glass tube, A the wire for communicating electricity, D the surface of quicksilver or fused tin for producing a vacuum, B the tube to be exhausted by the stop-cock C, after being filled by means of the same stop-cock when necessary with hydrogen, and EF the moveable tube connected with the air-pump. Sir H. Davy found, that in all cases when the mercurial vacuum was perfect, it was permeable to electricity, and rendered luminous either by the common spark or the charge of a Leyden jar. The intensity of these phenomena varied with the temperature. When the tube ABC was very hot, the electric light appeared on the vapour of the mercurial vacuum of a bright green colour, and of great density. As the temperature diminished it lost its vividness. At 20° below zero of Fahrenheit it was perceptible only in considerable darkness. When the minutest quantity of rare air was introduced into the mercurial vacuum, the colour of the electric light changed from *green* to *sea green*, and by increasing the quantity, to *blue* and *purple*. At a low temperature the vacuum became a much better conductor. A vacuum above fused tin exhibited nearly the same phenomena. At temperatures below zero the light was yellow, and of the palest phosphorescent kind, just visible in great darkness, and not increased by heat. When the vacuum was formed by pure olive oil, and by chloride of antimony, the electric light through the vapour of the chloride was more brilliant than that through the vapour of the oil; and in the last it was more brilliant than in the vapour of mercury at common temperatures. The light was of a *pure white* with the chloride, and of a *red* inclining to *purple* in the oil.

Plate CCXXIII, fig. 13.

and of temperature.

Colours of the spark.

Upon rarefying the air five hundred times in a glass vessel a foot long and eight inches in diameter, Mr Smeaton made the vessel revolve rapidly on a lathe, at the same time exciting it with the palm of his hand. A large quantity of lambent flame appeared under his hand, *variegated with all the colours of the rainbow*. Though the light was steady, every part of it was continually changing colours.

In carbonic acid gas the light of the spark is white and brilliant, and in hydrogen gas it is red and faint. When the sparks are made to pass through balls of wood or ivory they are of a *crimson* colour. They are *yellow* when taken over powdered charcoal, *green* over the surface of silvered leather, and purple from imperfect conductors.

Experiments on electrical light.

The following experiments on the spark and electrical light are both instructive and entertaining.

Exp. 1. Cover a metallic wire with silk, and form it into a close flat spiral of not more than twenty-four revolutions, with the different coils in contact. When a considerable electric charge (of about two square feet of coated surface) is passed through it, a vivid light resembling that of an artificial fire-work will be seen, even in daylight, originating in the centre of the spires. M. Nobili considers this light as electro-magnetic light, on account of its relation to the magnetic state of the spiral, and as similar to the aurora borealis.

Exp. 2. Take a bound book covered with rich gilding, and, holding it in one hand, bring it near the prime conductor. The spark will immediately shoot along the gilding in sparks or streams of green light, and will exhibit the pattern in the dark, and enable the observers to read the gilt title of the book.

Exp. 3. In the preceding experiment the letters themselves were covered with a metallic film; but if we construct an apparatus like that in fig. 14, on which the word LIGHT is left blank in a continuous line of narrow tinfoil pasted upon glass, and forming several parallel lines, and apply the ball B to an electrified prime conductor, the word LIGHT will be seen in the dark in luminous letters formed by the electric spark passing from one piece of tinfoil to the opposite one. Figures of all kinds may in a similar manner be delineated electrically.

Plate CCXXIII, fig. 14.

Exp. 4. Another beautiful experiment, called the *luminous spiral tubes*, is shown in fig. 15, where a number of round pieces of tinfoil are pasted spirally upon four glass tubes *a*, *b*, *c*, *d*, fixed on a board round a central rod of glass AB, supporting horizontally a wire *mn* with brass balls, and capable of turning round the pivot A. Electrify by sparks the wire at A, and pushing the wire *mn* gently round, the ball at the top of each tube will receive electricity from *a* or *b*, and a brilliant line of light will appear to surround each ball in succession, in consequence of the spark appearing between each of the small circles of tinfoil.

Luminous spirals, fig. 15.

Exp. 5. The *luminous jar* shown in fig. 16 is a still more beautiful experiment. In one which is now before us, fifty-five squares of tinfoil an inch square, and each perforated with a hole four-tenths of an inch in diameter, are pasted in five rows on the outside and inside of a glass jar AB, fig. 16, about five inches in diameter and eleven inches high. The diagonals of the square pieces are placed horizontal and vertical, and their points or angles are separated by about one-twelfth of an inch. The rows of the tinfoil squares are similarly placed on the inside of the jar, with this difference only, that their horizontal points nearly touch one another at the centres of the circular holes of the outer squares. The brass ball A communicates with the inside squares by a wire, and when it is charged by the prime conductor, a hundred and ten sparks will be seen at once in a horizontal, and a hundred and ten in a vertical direction, when the jar is discharged.

Luminous jar, fig. 16.

Exp. 6. Take a glass cylinder three inches wide and three feet long, so fitted up that a brass plate may be let down from the top of the cylinder, so as to stand at any distance from another brass plate fixed at the bottom of the cylinder. When the cylinder is exhausted of air in the usual manner, and the upper plate communicates with the prime conductor, and the lower one with the ground, a brilliant sheet of light will pass from the upper to the lower plate. If the distance of the plates is ten inches, and if the charge of a Leyden jar is made to pass from the one to the other, a continuous body of the most brilliant fire will pass between them.

The course taken by the electricity in the disruptive discharge is always in the line of least resistance, or that in which there is the smallest amount of insulating power; and if a number of bodies of different degrees of conducting power lie in its path, it will find its way through some and avoid others, as if it had the power of choosing the easiest and shortest line. The annexed drawing, taken from an experiment made by Sir W. Snow Harris, is an excel-

Phenomena and Laws.

lent illustration of this interesting property. In figure A, *a*, *b*, *c*, *d*, &c., are detached fragments of leaf gold laid down on a sheet of paper. A charge of about ten square feet of coated glass is then passed through this interrupted circuit from P to N, and the effect produced is shown in fig. B, where the shaded parts are the portions of the leaf gold burned up, and marking the path of the electricity, or the line of least resistance, P, *b*, *d*, *e*, *f*, *g*, *h*, *i*, N. The pieces *c* and *k* are left untouched, and also the white portions of the other pieces, while the portion *h* and N are wholly destroyed. This experiment finely illustrates the course taken by the lightning which strikes buildings and passes through the apartments of a house.

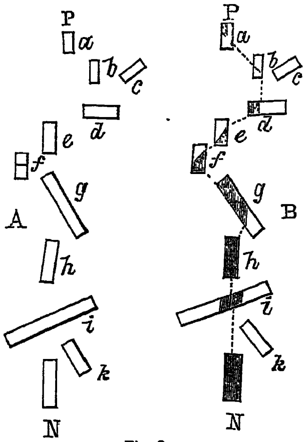

Fig. 2.

From ordinary electrical machines, sparks ten or twelve inches long have been obtained in rapid succession, by affixing a ball about two inches in diameter to the conductor, and projecting three or four inches from it, and then presenting to it a large ball connected with the earth or with the opposite conductor. When the discharge is made from a single jar, the striking distance is generally about an inch; but if we arrange a number of equal and similar jars, as shown in the annexed figure, where the course of the

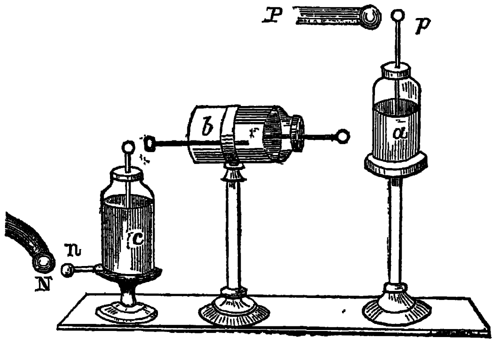

Fig. 3.

discharge is *P*, *p*, *a*, *b*, *c*, *n*, N, we obtain a long striking distance between the outer coating of the last jar and the knob of the first. Professor Dove of Berlin has shown that when such a succession of positive and negative surfaces is used the length of the spark increases with the square of the number of jars. If the jars are charged separately and equally, as suggested by Mr Baggs, and placed quickly as above directed, very near one another, but so as not to be in contact, a spark of great length and brilliancy will be produced.

Convective discharge.

When the electricity is discharged by pointed conductors, Dr Faraday has given it the name of the *convective* or *carrying discharge*, which consists in the motion of charged particles either of insulating or conducting matter from place to place.

Conductive discharge.

Another species of discharge, called the *conductive discharge* by Dr Faraday, takes place when the electricity is carried off by the intervening dielectric communicating their forces either rapidly as in the metals, or slowly as in spermaceti, air, glass, shell-lac, &c.[1]

A very pretty experiment has been made to show the short duration of the light of a spark. The experiment was, we believe, first made by Mr Wheatstone by painting three unequal sectors of a circular disc with the three prismatic colours, *yellow*, *red*, and *blue*. When it is made to revolve rapidly round its centre, the colours are mixed and form a grayish white tint. But if we darken the room and illuminate the revolving disc with an electric spark, the three colours will be distinctly seen. During the brief duration of the flash there was not time for the colours to make a combined impression on the retina and obliterate their individual action. This very interesting effect is not owing to the velocity of the electric light, but to its short duration, and may be produced by the flash of a copper cap or even of gunpowder. If we inclose a bright light, or even a candle, in a box having an aperture in one of its sides prolonged so that it can pass instantaneously before the light, and allow it to fall on the revolving disc, the same effect will be obtained.

This experiment is much more interesting when we use the revolving discs of the phenakistoscope, or when we place upon any one of them a few large and distinct letters. If a light of short duration is thrown upon the revolving discs when every figure or word is obliterated, the figures and words will be distinctly seen.

In like manner a current of fluid or of solid particles discharged with such a velocity as to appear a continuous stream, would if illuminated in the dark be exhibited in separate and distinct portions. The same effect is produced in daylight or any other light by viewing through revolving apertures a continuous stream of this kind, or the shoot flame of a coal fire, all of which derive their continuity from the duration of the impression made on the retina by the successive action of their different portions.

SECT. VI.—*On the Nature and Origin of Electrical Light.*

Nature of electrical light. Wollaston.

Dr Wollaston seems to have been the first person who made an accurate examination of electric light, and the following is all that he has published as the result of his experiments. "When the object viewed is a *blue* line of electric light, I have found the spectrum to be separated into several images; but the phenomena are somewhat different from the preceding (viz. the spectrum of the blue portion of the flame of a candle). It is, however, needless to describe minutely appearances which vary according to the brilliancy of the light, and which I cannot undertake to explain."[2] M. Biot, in speaking of electric light, remarks, "that if we look through a prism at the sparks which pass between two conductors oppositely electrified, we shall find all the colours which compose common light."[3]

Biot.

Fraunhofer.

M. Fraunhofer examined the electric spark in a more philosophical manner. In order to obtain a continuous line of electrical light, he brought to within half an inch of each other two conductors, and united them by a very fine glass thread. One of the two was connected with an electrical machine, and the other communicated with the ground. In this manner the light appeared to pass continuously along the fibre of glass, which consequently formed a fine and brilliant line of light. When this luminous line was expanded by refraction, Fraunhofer saw that, in relation to the lines of its spectrum, electric light was very different both from the light of the sun and from that of a lamp. In this spectrum he met with several lines partly very clear, and one of which in the green space seemed very brilliant compared with other parts of the spectrum. He saw in the orange another line not quite so bright, which appeared to be of the same colour as that in lamp-light spectra; but in measuring its angle of refraction, he found that its light was much more strongly refracted,

[1] Faraday's *Electrical Researches*, vol. i. p. 418.

[2] *Phil. Trans.*, 1802.

[3] *Traité de Physique*, tom. ii., p. 459.

Phenomena and Laws.

and nearly as much as the yellow rays of lamp light. In the red rays towards the extremity of the spectrum, he saw a line of very little brightness, and yet its light had the same degree of refrangibility as the clear line of lamp light. In the rest of the spectrum he saw other four lines sufficiently bright.[1] In a subsequent paper read at Munich in 1823, Fraunhofer observes, that, by means of the large electrical machine in the cabinet of the Academy of Munich, he obtained a spectrum of electric light, in which he recognised a great number of light lines, and that he had determined the relative places of the lightest lines, and the ratios of their intensities. What these positions and ratios were we have no means of knowing, as we believe that this distinguished philosopher has not given them to the public.

Brewster.

The nature of electric light has been more recently examined by Sir David Brewster. He had long ago shown that the light of electricity was refracted singly and doubly, and polarized exactly like all other light; but his recent observations were made, like those of Fraunhofer, on the dark and luminous lines which appear in the spectrum formed from it by a prism. Fraunhofer examined the electric light produced in the manner he has described. In this *species* of electric light Sir David Brewster observed the lines described by Fraunhofer, and also its remarkable difference from that of the sun and a lamp in relation to the fixed lines of the spectrum. This difference he found to arise from the fact that certain *colorific* rays which exist in solar light do not exist in electrical light, though, in some parts of the spectrum, other rays of equal refrangibility are visible. The extreme red space, for example, is wanting, and, generally speaking, much of the red and yellow light. Hence the light of the electric spectrum is *green* at a line or point of a given refrangibility, where it is *yellow* in the solar spectrum. These facts confirm in a remarkable manner the discovery that the spectrum consists of three superimposed spectra of blue, yellow, and red light, of equal lengths,[2] and receive from that discovery a complete explanation.

Sir David Brewster examined electric light of various colours, and produced under different circumstances, and he found it to differ in its composition in a very remarkable manner, each variety of electric light varying in the number, intensity, and position of its bright and defective rays. One species of electric light is as different from another as the coloured lights produced in the flame of alcohol in which different saline substances have been dissolved. It would require almost the lifetime of an individual to examine and make drawings of this class of phenomena while the light passes from a violet, through blue, green, yellow, and red, up to white light. The bright lines which occur in the green space have a most singular appearance. They shine, in reference to the rest, with the metallic brilliancy of silver; and each successive spark, obtained under nearly the same circumstances, will often present to us these lines under different intensities and characters.

Origin of electrical light.

It has been the general opinion of philosophers that the electric spark was the electric fluid itself, or, as Biot expresses it, "a modification of electricity itself, which had the faculty of becoming light at a certain degree of accumulation." This eminent writer, however, considered this opinion as erroneous, and has devoted a whole chapter to prove that electric light has the same origin as the light disengaged from air by mechanical pressure, "*and that it is purely the effect of the compression produced on the air by the explosion of electricity.*" In order to establish this

Theory of M. Biot.

theory, M. Biot has stated, on the authority of several experiments, "that the intensity of electric light depends always on the ratio which exists between the quantity of electricity transmitted and the resistance of the medium; and he has shown, by an experiment with Kinnersley's air thermometer, "that at each spark the air of the cylinder, driven by the repulsive force, presses on the surface of mercury, which rises suddenly in the small tube, and falls back again immediately after the explosion." "This indication," he adds, "proves the separation produced between the particles of the mass of air where the electricity passes; and from what we know of its extreme velocity, it is certain that the particles exposed immediately to its shock ought in the first moment to sustain individually all the effect of the compression. They ought, then, from this cause alone to disengage light as when they are subjected to any other mechanical pressure. *Thus one part at least* of the electric light is *necessarily* due to this cause; and this being the case, there is no experiment which can lead us to conjecture that it is not all due to this cause."[3]

These arguments, whatever may be their weight, carry no conviction to our mind. When we possess two series of accurate experiments, by which it is proved that light produced by mechanical pressure in air and gases, of different bulks, and of different degrees of temperature, rarefaction, and condensation, has the same colour, the same composition, and the same general character, as the light produced by electricity in passing through air and gases under the very same circumstances, we shall regard this theory as deserving of consideration.

M. Biot, anticipating the objection that electrical light is produced in the best vacuum, replies, that a vacuum such as we can produce is filled with vapours and gas, and that the barometric one is filled with mercurial vapour. Still, however, the light produced is not produced by air, and it should be shown that mechanical pressure is capable of eliciting light in such a vacuum; at all events, the light ought to bear some proportion to the degree of rarefaction, whereas Sir H. Davy obtained a bright light in the best vacuum with mercury, and the same light in the best vacuum with melted tin.

Anticipating another objection from the fact that the electric spark, when intense, passes through water, M. Biot gives a double reply, 1*st*, that the water itself is probably compressible, and therefore, we presume, gives out light during its compression; and, 2*dly*, that water always contains in combination a certain quantity of air, which may also contribute to the result. It would be desirable, therefore, to ascertain if water, and water with much air, give out light by mechanical compression.

In explaining the fact that electrical light is *violet* when the electricity is *feeble*, and of a *brilliant whiteness* when it is produced by a violent discharge, M. Biot remarks that "this variation of tints discloses still further the origin of the light; for we observe it in substances which burn according as the combustion is slow or rapid; that is to say, according as the oxygen of the air which this combustion absorbs is more or less rapidly condensed. The light which sulphur disengages when it begins to inflame is as *violet* as that of feeble electricity, but that of sulphur in vigorous combustion is *white*." The views upon which this argument is founded are themselves hypothetical. It is by no means made out that the colour passes from *violet* to *white* as the intensity of combustion increases; and, in the very case of *sulphur* referred to by M. Biot, Sir John Herschel has proved, that when it is inflamed in a white hot crucible, it gives out neither *blue*, *green*, nor *red* rays, but solely *homogeneous yellow light*, of a very definite refrangibility, and which contains few of the elements of *white* light.

Sir H. Davy's theory.

A more philosophical view of the probable origin of electrical light has been hinted at by Sir Humphry Davy, in

[1] Fraunhofer, *Bestimmung*, &c., 1814–15, p. 29.

[2] *Edin. Trans.*, vol. xii.

[3] *Traité de Physique*, tom. ii., p. 463.

Phenomena and Laws.

his paper of 1822, already quoted. "The circumstance," says he, "that the intensity of the electrical light in the mercurial vacuum diminishes as it is cooled to a certain point, when the vapour must be of infinitely small density, and is then stationary, seems strongly opposed to the idea that it (electrical light) is owing to any permanent vapour emitted constantly by the mercury. The results with tin must be regarded as more equivocal; because, as this substance cannot be boiled in vacuo, it may be always suspected to have emitted a small quantity of the rare air or gas to which it has been exposed; yet, supposing this circumstance, such gas must be at least as highly expanded as the vapour from cooled mercury, and can hardly be supposed capable of affording the *dense* light which the passage of the charged Leyden phial through the vacuum produces.

"When the intense heat produced by electricity is considered, and the strong attractive powers of differently electrified surfaces, and the rapidity of the changes of state, it does not seem at all improbable that the superficial particles of bodies, which, when detached by the repulsive power of heat, form vapour, may be likewise detached by electrical powers, and that they may produce luminous appearances in a vacuum, free from all other matter, by the annihilation of their opposite electrical state.

"In common cases of electrical action, the quantity of the heat generated by the annihilation of the different states depends upon the nature of the matter on which it acts; and in cases where electrical sparks are taken in fluids, vapour or gas is always generated; and in elastic fluids, the intensity of the light is always greater the denser the medium."[1]

Discoveries of Dr Fusinieri.

About the same time that Sir H. Davy was occupied with these researches, Dr Fusinieri was engaged in those beautiful experiments on electric light which have added so greatly to our knowledge of its nature and origin. The results of these experiments, which seem to have been commenced in 1821, were published in successive years. In 1825 there appeared in the Journal of Pavia a most interesting communication, of which the following is a brief abstract, relative to the transport of ponderable matter in the electrical discharges of ordinary machines; and, in 1831, another of equal importance on the transport of ponderable substances by lightning.

Dr Fusinieri has proved that the electric spark which issues from a *brass* conductor, and traverses air, contains brass in the state of fusion, and incandescent molecules of zinc.

When the spark issues from a globule of *silver*, it contains in its passage through air silver in fusion, and incandescent molecules of the same metal.

If the spark which issues from silver traverses a plate of copper, the silver which it contains passes also through the copper in perforating it, and in traversing even a space of several centimeters, if the passage is oblique from the one surface to the other.

In this passage a portion of the transported silver is detained in the aperture which is made in the copper, and another portion follows the current, and penetrates the ball which receives the electric spark.

When the electric spark issues from a ball of *gold*, and passes into air, it contains gold in a state of fusion, and also incandescent molecules of gold.

If the spark from *gold* traverses a plate of *silver*, the gold contained in the spark traverses the plate in piercing it; and in traversing a space of several centimeters in the silver, if the direction of the passage is oblique, a part of the transported gold remains in the silver, and spreads itself over the two surfaces of the plate, and another part accompanies the electric current, and penetrates the ball which receives the spark. The gold spread over the polished surface of the silver appears in the form of a thin circular stratum upon the surface where it enters, and upon the surface where it leaves the plate. The very same result takes place if the spark passes from brass to silver.

These strata or metallic spots are so exceedingly thin, that after a certain time they are volatilized and disappear.

Dr Fusinieri also found that in each passage of the spark there was an opposite and reciprocal transport of the two metals. In a spark from silver to copper, part of the copper is transported to the silver, as well as the silver to the copper; and the same reciprocal transfer takes place in a spark from gold to silver.

Accompanying this reciprocal transport, there are two strong and opposite percussions produced by the transported metal, one at the point where it is detached, the other at the point where it enters the other metal. These two percussions show themselves, by two opposite cavities which contain the same metal, in such a state as to indicate fusion. Here the transported metal exerts two pressures in opposite directions.

In passing from one metal to another, the electric current leaves the first metal in the second, and takes with it a small quantity of the second.

The electric spark which issues from a metal into air contains a group of molecules, the most central of which are in a state of simple fusion, and the exterior ones are in a state of greater or less combustion, from their contact with oxygen, according as the metal is more or less oxidable; and the matter thus contained in the spark is endowed with a force of spontaneous expansion.[2]

From these highly interesting facts Dr Fusinieri draws the following important conclusions respecting the nature and origin of electric light. 1. The electric spark is not formed by a pure fluid, or by any imponderable fluid. 2. The heat and light of the spark proceed from the ignition and combustion of the particles of ponderable matter. 3. The presence of air produces on the spark two distinct effects, the one to hinder its free expansion in space, the other, by supplying oxygen, to promote the combustion of the exterior molecules of the group, while the central molecules are luminous from ignition and fusion alone. 4. In gases without oxygen, the material molecules which compose the spark ought to be simply in a state of incandescence and fusion, without any combustion of the exterior particles of the group, in the same manner as this takes place for the central parts of the spark in common air. 5. In gases deprived of oxygen, as well as in a vacuum, the molecules which compose the spark ought to be incandescent; that is, in a state which fits them to emit light and heat; a phenomenon of the same kind as those inflammations which chemical experiments prove to take place even without the aid of oxygen, in so great a number of other combinations, or even without there being any new combinations, by the sole effect of division of parts.

In a later memoir on the transport of ponderable substances by lightning, published in the *Ann. delle Scienze del Regno Lomb. Veneto* for 1831, Dr Fusinieri has shown, by a series of laborious and beautiful observations, that lightning leaves in houses and on trees traces of ferruginous and sulphureous substances which it contains; and he infers that iron exists in the clouds, having been attracted[3] from the earth, and principally from mountains, where the mines

[1] *Phil. Trans.*, 1822, pp. 72, 73.

[2] Dr Fusinieri likewise found that the electric spark obtained between the two poles of the voltaic pile, terminated either by metals or charcoal, contains also particles of these substances extremely divided, and in a state of combustion.

[3] The iron may be carried off by the lightning which issues from the ground in cases where the clouds are negatively electrified.

Phenomena and Laws.

are more abundant, and where storms generally begin to form. Hence, as Dr Fusinieri supposes, we may connect this fact with meteoric stones, and with the magnetic currents which surround the globe.

That the electric spark *is a flame*, and consists, like all other flames, of incandescent molecules in a state of minute subdivision, will, we think, be now admitted by every philosopher; and it cannot fail to be observed how singularly this result harmonizes with the varied composition of electric light of different kinds and colours, as ascertained by Sir David Brewster by means of prismatic analysis;—and from the comparison which he is making between the composition of electric light consisting of different ponderable substances, and that of flames in which the same ponderable substances exist in a state of incandescence, there is reason to expect that these two widely separated classes of phenomena may be strictly identified.

Sect. VII.—*On the Law of Electrical Attraction and Repulsion, and the Attraction of Spheres and Planes.*

Law of electrical attraction and repulsion.

It is obvious, from the simplest experiments, that the force of electrical attraction and repulsion diminishes with the distance. In the theories of Æpinus and Cavendish nothing more than this simple fact has been assumed. Newton had supposed that the forces of electricity and magnetism decreased with the cube, or some higher power, of the distance. Lord Stanhope inferred, from reasonings not very conclusive, that the law was the same as that of gravity; and Dr Robison, so early as 1769, ascertained, from more than a hundred experiments, that the repulsive force diminished according to a power of the distance whose exponent was 2·06, or very nearly as the square of the distance.

Coulomb's torsion balance.

The accurate determination, however, of the law of electrical attraction and repulsion was left to Coulomb. The apparatus which he employed for this purpose, and which is known by the name of the *torsion balance*, is represented in Plate CCXXIV., fig. 1, where ABCD is a glass cylinder, which is covered with a plate of glass AB thirteen inches in diameter. This plate is perforated with two holes *e* and *a*, the former being intended to receive a tube of glass *e*G two feet high, carrying on its upper end a torsion micrometer, consisting of a graduated circle MN, an index M, and a pair of pincers, opened and shut by a ring, for holding a slender silver wire GH, whose lower end H is also grasped by a similar pair of pincers made of copper, and about a line in diameter. Through a hole in these copper pincers there passes a horizontal needle *cd*. This needle consists of a silk thread or a straw covered with sealing-wax, but the end of it, at *d*, about eighteen lines long, is a cylinder of gum-lac. It is terminated at *c* by a ball of the pith of elder about two or three lines in diameter, and at *d* by a vertical plane of paper covered with turpentine. A circular band of paper EF, divided into 360°, is pasted round the cylinder on a level with the needle, and at the hole *a* there is introduced a small cylinder *ab*, the lower end of which, made of gum-lac, carries another ball *b* of the pith of elder. The instrument is adjusted when a line passing through the centre of the silver wire GH at P passes also through the centres of the balls *b* and *c*, and points to the zero of the graduated circle EF.

Plate CCXXIV., fig. 1.

Law of the repulsive force. Fig. 2.

Having fixed a brass pin BC, fig 2, with a large head B, into a handle of sealing-wax AC, and having electrified the ball B, Coulomb communicated its electricity to the balls *b*, *c*. They accordingly repelled each other, and the needle *cd* turned round through a certain arch. By turning, however, the micrometer button in the direction NP, he twisted the wire GH, and caused it to return to its first position, and point to the zero of the scale. When this is done, the force of torsion has been made to balance the repulsive force of the two balls *b*, *c*; so that, by comparing the forces of torsion which balanced the repulsive forces at different distances of the balls, he obtained measures of the repulsive force at these distances. When the distances were 36°, 18°, and $18\frac{1}{2}$°, he found the angle of torsion, or the force of torsion, which is proportional to the angle, to be 36°, 144°, and $575\frac{1}{2}$; that is, at *half* the distance the force is *four* times greater, and at a *fourth* of the distance the force is nearly *eight* times as great. Hence he concluded that *the repulsive force of two small globes charged either with positive or negative electricity is inversely as the squares of the distances of the centres of the globes.*

Law of the attractive force.

In applying the same method to determine the law of the attractive force which takes place between two oppositely electrified bodies, M. Coulomb met with a difficulty, arising from the attractive force increasing in a greater ratio than the force of torsion. From this cause it was difficult to prevent the balls from coming into contact, and a delay was created, during which part of the electricity had escaped. By providing against this difficulty, he obtained results which led to the conclusion *that the attractive force of two small globes, one electrified positively and the other negatively, was in the inverse ratio of the squares of the distances of their centres.*

In order, however, to confirm this result by an entirely different method, he employed the apparatus shown in fig. 3, where BC is a vertical stand of wood, carrying a horizontal arm of wood AB, divided into inches, upon which there slides another piece of wood ED, to which is suspended, by a fibre of silk *fe*, a horizontal needle of gum-lac *cd*, fifteen lines long, carrying at one end, and perpendicular to the needle, a circle of gilt paper *d*, seven lines in diameter, and at the other end a ball *c* of gum-lac. A globe of copper a foot in diameter, or a globe of paper covered with tinfoil, resting on four insulating cylinders of glass, coated with sealing-wax, is then placed upon a stand, so that it can be raised or depressed, and fixed in any position, its horizontal diameter passing through *dc*. Fig. 3.

This apparatus is adjusted by placing the globe so that, when the moveable piece E is at *zero* of the scale on BA, the centre of the circle *d* may just touch the globe. When this is done, place the piece E at three inches on the scale, so that the distance of *d* from the globe will be three inches, and then the distance of *d* from the centre of the globe will be nine inches. Let the globe be now electrified by the spark of a Leyden jar; then, if a conductor is made to touch the plate *d*, the globe will communicate to it the opposite electricity upon removing the conductor, and the globe and the plate will attract one another. Cause the needle *cd* to oscillate through an arch of about 20° or 30° from the line where the force of torsion is nothing, and observe the time in which a given number of oscillations, suppose fifteen, is performed. Repeat the very same experiment when the piece E is placed at twelve and eighteen inches on the scale; that is, when the distances of the centres of the attracting bodies are eighteen and twenty-four inches. In doing this, Coulomb obtained the following results:

Distances of centres.	Number of oscillations.	Time in which they were performed.
9	15	20
18	15	40
24	15	60

As the oscillations in the preceding experiments are produced by the attraction of the globe and plate *d*, in the same manner as the oscillations of a pendulum are produced by the force of gravity; then, since the time in which a given number of oscillations is performed is inversely as the square root of the attractive force, and if we assume that the attractive force is inversely as the squares of the distances, or 9, 18, 24, or 3, 6, 8, then it will follow that the time of oscillation is proportional to

Phenomena and Laws.

these distances. These times will consequently be 20″, 41″, and 54″, if the attractive force is inversely as the square of the distance; but by experiment the times were 20″, 40″, and 60″. The difference is, therefore, almost nothing at 18 inches of distance, but it is nearly $\frac{1}{10}$th at 24 inches. Coulomb has applied a correction to the number 54″, in consequence of the loss of electricity by the two bodies during the four minutes which the experiment occupied. He found by experiment that the action was diminished $\frac{1}{40}$th of the whole per minute, and consequently $\frac{1}{10}$th of the whole in four minutes. Hence, $\sqrt{10} : \sqrt{9} = 60'' : 57''$, a result which now differs only $\frac{1}{20}$th from 60″, the time determined by experiment. Hence it follows, that by both methods of observation, the law of action is the same for attractive as it is for repulsive forces.

We are not aware that these experiments of Coulomb have been repeated and confirmed by other philosophers. Experiments with the torsion balance and contact plane are very difficult and precarious, and it is almost impossible to estimate with accuracy the loss of electricity in the two charged conductors during the performance of the experiment.

Experiments of Sir Snow Harris.

Under these circumstances, Sir Snow Harris of Plymouth has resumed the subject, and, by new methods of observation and instruments of great accuracy, he has confirmed the law given by Coulcomb, both in the case of simply electrified conductors, and in bodies upon which given quantities of electricity have been accumulated. A more particular account of these instruments, and of the method of applying them, will be given in a subsequent part of this article.

The law of the attractive force is easily obtained when the opposed surfaces are parallel planes or rings; but in the case of spherical conductors and bodies of other forms, the conditions become more complicated. Considering the distribution of the electricity on the spheres to be uniform, and the whole force exerted to be as the number of attracting points directly, and as the squares of the distances between the respective points inversely, Sir Snow Harris has shown that *the forces between two spheres will be inversely as the distances between their nearest points multiplied into the distances between their centres.*

Harris's experiments on the attractions of spheres and planes.

In order to submit this result to the test of experiment, he used two spheres whose radius was an inch, and obtained by means of his electrical balance the following results:

Distance of Centres of Spheres.	Distance of nearest Points by experiment.	Calculated Distance of the Points in each Sphere in which the Force may be supposed to be collected.	Force in Grains.
2·2	0·2	0·664	12·0
2·5	0·5	1·117	4·25
2·8	0·8	1·496	2·25
3·0	1·0	1·732	1·75

These results confirm the law deduced from theory, and Sir Snow Harris has established its truth more completely by extending it to several new cases, the most important of which, with the deductions, are as follows:

1. Two spheres at the distances in column 1, exert the same force as two circular planes of equal areas at the distances in column 3.

2. The attractive force of two opposed conductors is not influenced by the form or disposition of the unopposed portions. The attractive force, for example, is the same, whether the opposed bodies are merely circular planes, or planes backed by hemispheres or cones. Two hemispheres also attract each other with the same force as the spheres of which they are hemispheres.

3. The force between two opposed bodies is directly as the number of attracting points, the distance being the same. Thus two circular planes of unequal diameter do not attract each other with a greater force than that of two similar areas, each equal to the lesser. In like manner, the attractive force between a ring and a circular area of the same diameter is equal to that exerted between two similar rings, each equal to the former.

4. The attractive force between a spherical segment and an opposed plane of the same curvature, is equal to that of two similar segments on each other.

Sect. VIII.—*On the Dissipation of Electricity by the Contact of Air, and by Imperfect Insulation.*

Dissipation of electricity by air.

If we place an electrified body upon a mass of gum-lac, which is the worst of all conductors, or the best insulator of electricity, we shall find that, in a certain time, the whole of its electricity has disappeared. In like manner, if we suspend the same body under the same circumstances by a long fibre, or very small cylinder of gum-lac, we shall also find that in this last case the electricity will wholly disappear in a certain time; but the time in this last case will be much longer than in the first case. If we perform the same experiments in rarefied, moist, or hot air, we shall find that the electricity disappears faster than in condensed, dry, and cold air.

In all these cases the electricity is said to be *dissipated;* and it becomes an interesting as well as a most useful inquiry to determine the separate influence of these different causes in carrying off the electricity of electrified bodies.

The only observations which we possess on this subject we owe to the ingenuity and industry of M. Coulomb.

By means of the torsion balance he determined, in four days—two in May, one in June, and the last in July—the ratio of the electric force lost per minute to the total mean electrical force of the body, the electrical density varying in the five or six experiments which were made in each day. The following were the results:—

May 28. Ratio of the Force Lost.	May 29. Ratio of the Force Lost.	June 22. Ratio of the Force Lost.	July 2. Ratio of the Force Lost.
$\frac{1}{40}$	$\frac{1}{56}$	$\frac{1}{13\frac{1}{2}}$	$\frac{1}{14}$
$\frac{1}{38}$	$\frac{1}{61}$	$\frac{1}{11}$	$\frac{1}{19}$
$\frac{1}{42}$	$\frac{1}{54}$	$\frac{1}{13}$	$\frac{1}{30}$
$\frac{1}{42}$	$\frac{1}{58}$	$\frac{1}{13\frac{1}{2}}$	$\frac{1}{19}$
	$\frac{1}{54}$		
Mean, $\frac{1}{40\frac{1}{2}}$	$\frac{1}{56\frac{3}{4}}$	$\frac{1}{12\frac{3}{4}}$	$\frac{1}{20\frac{1}{2}}$

Hence, in reference to the state of the atmosphere on the days of observation, we have

	Mean Ratio of Force Lost per Minute.	Barometer Inches.	Thermometer of Reaumur.	Hygrometer of Saussure.
May 28	$\frac{1}{40\frac{1}{2}}$	28·3	15½°	75°
May 29	$\frac{1}{56\frac{3}{4}}$	28·4	15½	69
June 22	$\frac{1}{12\frac{3}{4}}$	27·11	15¾	87
July 2	$\frac{1}{20\frac{1}{2}}$	28·2	15¾	80

Phenomena and Laws.

By examining the results for each day in the first of the preceding tables, it will appear that the ratio of the electric force to the whole force is a constant quantity during the same day, or when the air has the same degree of moisture. Hence it follows,

1st, *That the loss of electricity is proportional, in the same state of the air, to the electrical density;* from which it follows, as Coulomb has shown,

2d, *That the ratio of the force lost in a minute to the total force, is double of the ratio of the loss of intensity of each body to the total density.*

From a great number of experiments made with balls of different magnitudes, and when the quantity of electricity, as well as the electrical density of each ball, were very different, he found,

3d, *That the ratio of the dissipation of the electric force during a minute, to the total force, is uniformly a constant quantity.*

By using a globe a foot in diameter, cylinders of all lengths and magnitudes, circles of paper and of metal, &c., he found,

4th, *That when the air was dry, and the degree of electricity not great, the ratio of the decrease of the electrical density to the density itself is always a constant quantity, whatever be the form or the magnitude of the electrified body.*

By using *pith balls*, and balls of *copper* and *sealing-wax*, he found,

5th, *That the law of dissipation is not influenced by the nature of the body.*

It appears, from the second of the preceding tables, that the dissipation increases with the degree of moisture, as indicated by Saussure's hygrometer; and, by comparing the observations, he concluded,

6th, *That the diminution of the repulsive force, or, what is the same, of the electric density, is proportional to the cube of the weight of the quantity of water dissolved in a given quantity of air.* He found also,

7th, *That the dissipation of electricity increases with the temperature.*

In the course of these valuable researches Coulomb ascertained that there was no dissipation along the fibre which supported the electrified bodies which he employed; and he found also that there were other causes of dissipation, which produced effects of a considerable amount, and which yet remain to be discovered.

Effect in a vacuum.

But though electricity is thus retained on the surface of bodies by the bad conducting power of air, it is not, as might have been expected, entirely dissipated in a vacuum. M. Becquerel has proved that in a vacuum so perfect that where the atmospheric pressure is only the 25th of an inch, a body preserved its electricity for ten days; and he has more recently shown in his Treatise on Electro-Chemistry by means of a gold-leaf electroscope, that if an electrified body is placed in a perfect vacuum, at a distance from objects that could act upon it electrically by influence, such a body will preserve a certain quantity of electricity for an indefinite time.

Dissipation by imperfect insulation.

Having thus determined the laws of dissipation by the contact of air, Coulomb proceeded to inquire into the causes of dissipation along imperfectly insulating bodies. The experiments which he performed for this purpose were made on the same days with those made on the dissipation by air, so that he was able to determine by calculation the portion which was lost by aërial contact, and the portion lost by imperfect insulation.

When a highly electrified ball was suspended by a silk fibre, the dissipation of its electricity was much more rapid than it should have been by the contact of the air, and therefore a part of it was owing to the imperfect insulating power of the silk thread. But when the intensity of the electricity was diminished to a certain degree, the silk fibre was as good an insulator as the gum-lac. A cylinder of gum-lac eighteen lines long did not cease to insulate perfectly till the degree of electricity was nearly *triple* of that which is insulated by the silk fibre.

Coulomb likewise found, that when a silk thread, or hair, or any fine cylindrical electric, began to insulate perfectly, the electrical density of the body which was insulated was proportional to the square root of the length of the support; that is, if a silk fibre *one* foot long insulates perfectly when the electrical density is D, it will require a fibre *four* feet long to insulate perfectly when the electrical density is 2 D, or double.

M. Coulomb's experiments seem to have been made only with one kind of electricity. M. Biot, however, found that the dissipation was nearly the same, whether the insulated body was electrified negatively or positively.

Sect. IX.—*On the Distribution of Electricity.*

Distribution of electricity.

When any body is electrified by presenting it to the prime conductor, the electricity, though it enter at one part of the body, is obviously distributed over the whole of it, as every part of the body gives distinct indications of its new state. It becomes an interesting inquiry, therefore, to ascertain by what powers the electricity is thus distributed over the body; to determine whether it is distributed throughout the substance of the body, or only on its surface; and to discover the laws of its local distribution, whether it exists on single bodies, on two or more equal or unequal bodies placed in contact, and on bodies of different forms.

These various topics have been treated by Coulomb with that ingenuity and sagacity which distinguish all his labours; and his torsion balance is the principal apparatus which was found necessary.

In order to determine whether electricity was distributed over conductors by a repulsive force between the particles of the electric fluid, or by some affinity or electric attraction for one body in preference to another, he found, by using a pith ball and a ball of copper, that the pith ball received exactly one-half of the electricity of the ball of copper, and that the ball of copper had no more affinity or electric attraction for the electric matter than the pith ball. This experiment was varied by using a disc or circle of iron ten lines in diameter, and a paper disc of the same size. In this case also he found that the electricity was equally distributed between the two discs; and he obtained the same result by using various other substances, and performing the experiments with a large torsion balance, with globes of five or six inches diameter.

In all experiments of this kind, the two balls must be allowed to remain a short time in contact, as several seconds elapse before an imperfectly insulating ball is capable of acquiring from the other half of its electricity. When the experiment is made with circular discs, the surface of the one must be placed symmetrically on the surface of the other.

Superficial distribution of electricity.

In order to determine whether the electricity pervaded the whole substance of the conductor, or was distributed on its surface, Coulomb provided an electrometer, consisting of a small circle of tinsel, suspended by a fibre of gum-lac, which, when suspended in a cylinder of glass, is so extremely sensible that a force equal to the *sixty thousandth* part of a grain was sufficient to repel the ball of the needle through an arch of more than ninety degrees.

The conductor whose electrical state he proposed to examine was a solid cylinder of wood four inches in diameter, and pierced with several holes four lines wide and four deep. This cylinder was then supported upon an insulating stand, and electrified by sparks from a leaden jar. He

Phenomena and Laws.

then took a small circle of gilt paper called the *proof plane*,[1] one and a half line in diameter, and about the eighteenth part of a line in thickness, and he insulated it at the extremity of a cylinder of gum-lac a line in diameter.

Having electrified the tinsel of his electrometer, he brought the proof plane into contact with the surface of the electrified wooden cylinder, and upon presenting the circle to the electrometer it repelled the tinsel with great force. The proof plane was then introduced into one of the holes of the cylinder, so as to come in contact with the bottom of the hole, and rest upon it. When it was taken out, without touching the sides of the hole, and presented to the electrometer, it gave no indications of electricity. In the first case, the proof plane carried off electricity from the part of the surface which it touched; but in the second case it carried off none, so that their was no electric matter in the interior of the cylinder, even at the depth of four lines.

Experiments by Biot; Plate CCXXIV., fig. 4.

These curious results, thus established by accurate observation, may be proved by two very pretty experiments, which have been given by Biot. Let S, fig. 4, be a spheroid of conducting matter, suspended by a perfectly insulating fibre A of gum-lac. Form two cups B, C, made of gilt paper or tinfoil, or any other conducting material, so as to fit exactly the spheroid when united, and fix to each of them an insulating handle L, L of gum-lac. Electrify the spheroid S, and holding a cup in each hand by the handles L, L, apply them, as in the figure, to the surface of the spheroid. Upon withdrawing the cups, it will be found that they have abstracted from the spheroid S all its electricity, and that so completely, that it will not affect the most delicate electrometer, while the cups will be found to possess the same quantity of electricity which originally existed in the spheroid.

Fig. 5.

The other experiment of M. Biot is shown in fig. 5, where A B is an insulated cylinder, moveable round a horizontal axis, and which may be turned by the winch H, composed of several rods of glass. Around the cylinder there is wrapped a metallic ribband CD, whose extremity D terminates in a semicircle, and is attached to a silk cord F. This apparatus is made to communicate with an electroscope E, composed of two linen threads carrying two-pith balls. When the metallic ribband is electrified, the balls and the threads will diverge. Upon unrolling the metallic ribband, by pulling the silk thread F, the pith balls at E collapse, and indicate a diminution of the electrical repulsion; and if the ribband be sufficiently long, compared with the electric charge given to the apparatus, the separation of the balls may become quite insensible; but they will again diverge, and indicate an increase of electrical intensity, if we again roll up the ribband upon the cylinder.

by Faraday.

Dr Faraday has demonstrated the superficial distribution of electricity by some elegant experiments. Having made a cylinder of metallic gauze, or a trellis of iron wire with meshes not very wide, he places it on a horizontal disc of metal resting on a pillar of glass. When the interior surface of the cylinder is electrified, the electricity passes to its exterior surface notwithstanding its easy communication with the inner surface. If the cylinder is so powerfully electrified as to yield vivid sparks, a mouse or any other animal placed within it will experience no shock.

The same truth is finely demonstrated by another experiment of Dr Faraday. By means of a ring of wire AB, he forms a conical muslin bag ACB, and supports it upon a glass stand BD. When the bag is electrified, its interior surface is found by the proof plane to be entirely free of electricity; but if by means of the insulated silk thread S′ C, we pull it outside in, it will be found that the electricity has passed to the outside of the cone. In like manner, if by means of the thread C S we pull it back to its first position, we shall find that the electricity has again passed into the outer surface of the bag.

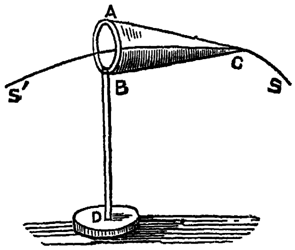

Fig. 4.

Method of measuring the distribution of electricity.

Having thus ascertained that electricity occupies the surfaces of conductors, the next point to determine is the law of its distribution in bodies of different forms, that is, to ascertain its intensity, or the electrical density, at different points of the surface.

Plate CCXXIV., fig. 6.

The following was the method used by Coulomb for this purpose: In the balance with which he made his first experiments he suspended his needle by a fine silver wire. He then took a cylinder of gum-lac, and having bent it as shown at *ced*, he attached to it a circle of gilt paper *d*, five or six lines in diameter, and the eighteenth part of a line thick. Having electrified the body whose electrical density was to be ascertained, he electrified the disc, carried by the needle by means of an insulated pin as formerly, and then touched the circle *d* with any part of the body where he wished to ascertain the electrical density. This circle was then placed in the balance, and the quantity of its electricity measured. Hence, as the quantity which the circle acquires by its tangential contact with the body is either the same as that of the point which it touches, or proportional to it, it became easy to ascertain the electrical density of different points of conductors, by touching those points with the circle *d*, and subsequently measuring its electricity. During the time, however, which elapses between different observations, a part of the electricity will be dissipated, so that an error is necessarily introduced in comparing the electrical density of any two points *a* and *b*. In order to correct this error, he proceeds thus: Having measured the electricity in *a*, he then, after an interval, suppose of three minutes, measures the electricity in *b*. He then re-measures the electricity in *a* three minutes after he measured the electricity of *b*, and the mean of these two measures for *a* will be the electrical density of *a* at the time when that of *b* was measured.

Distribution of electricity on a globe; and on the surface of a cylinder.

By the method now described Coulomb measured the distribution of electricity on a conducting sphere, and he found that the electrical density was the same on every part of it.

In a similar manner Coulomb found that the electrical density on the middle of a cylinder is to that of its extremity as 1·00 is to 2·30; that the density of the middle was to that of a point two inches from the extremity, as 1·00 to 1·25; and that the density in the middle was to that of a point situated in the hemisphere which terminated the cylinder, and one inch from its extremity, as 1·00 to 1·80. Hence it appears that the electricity is very much condensed upon the two last inches at the extremity of the cylinder, and that it varies very slightly from the middle to within two inches of the extremity.

Relative electrical densities of two globes in contact.

From various experiments, conducted in a way analogous to that already described, Coulomb obtained the following results relative to the manner in which the electrical fluid distributes itself between two globes A, B, of different diameters, after they have been placed in contact, and se-

[1] The employment of the proof plane, shown in Plate XXII., fig. 6, as used by Coulomb, has been objected to by Sir Snow Harris. M. Delarive agrees with Sir Snow that in bodies of an irregular form it may not give correct results, and proposes to use a simple electroscope with a very light ball, and having the same electricity as the body to be examined. The degree of repulsion which it experi nces at different points will be the measure of their electricity.—*Treatise on Electricity*, vol. i., p. 81.

Phenomena and Laws.

parated, so that the electricity is distributed uniformly over their surfaces.

Ratio of the Radii of the Globes. A B	Ratio of the Surfaces of the Globes. A B	Ratio of Electrical Densities. A B
1 to 1	1 to 1	1 to 1
1 ... 2	1 ... 4	1·08 ... 1
1 ... 4	1 ... 16	1·30 ... 1
1 ... 8	1 ... 64	1·65 ... 1
1 ... Infinity.	1 ... Infinity.	2·00 ... 1

In order to explain this table, we shall take the case of two globes $6\frac{1}{4}$ inches and 24 inches, which were actually used by Coulomb. The small globe of $6\frac{1}{4}$ inches having been electrified, it was touched with the other globe of 24 inches, and when they were separated, so that the electricity of each was uniformly diffused over their surfaces, it was found that the *quantity* of electricity possessed by the large globe was to that possessed by the small one as 11·1 to 1; but as the surfaces of the two globes are as 14·8 to 1, a greater ratio than the other, it follows that the two globes are not charged with electricity in a ratio as great as that of their surfaces; that is, a given area on the small globe contains a greater quantity of electricity, or has a greater electrical density, than the same area in the large globe. The electrical densities in the third column are therefore found by dividing the ratio of their surfaces by the ratio of the quantities of fluid which they contain, and the quotients will be the ratio of the densities given in the third column. Thus, in the present case, $14·8 \div 11·1 = 1·3333$, the electrical density of the small globe $6\frac{1}{4}$ inches in diameter, that of the large one of 24 inches being 1.

Such is the electrical state of two electrified globes when placed at a distance. It now becomes a curious point to ascertain how the electricity is distributed when one or more equal or unequal globes are in contact. When two equal globes are in contact, the thickness of the stratum of electricity, if it varies in thickness, or the electrical density if it is equally thick, is nothing at the point of contact, but increases from the point of contact equally in different azimuths to the opposite point of the globes, where it is a maximum. This law of increase varies with the ratio of the diameters of the globe.

Two equal globes.

In the case of two equal globes, the electrical densities at different distances from the point of contact were as follows:—

Distances from the Point of Contact.	Ratio of Electrical Densities.
0°	0
20	0
30	1
60	3·72
90	4·78
180	5·03

Two unequal globes.

When two unequal globes are in contact, the one being *twice* the size of the other, the density of the small globe was almost nothing at 30°. From 60° to 90° it increased in the ratio of 10 to 17, and from 90° to 180° in the ratio of 75 to 100.

When the one globe was *four* times the size of the other, the density of the *small one* was nothing up to 30°, from 30° to 45° it rose to 1, at 90° it was 4, and at 180° it was 5·72. The density of the *large globe* was nothing to the fourth or fifth degree from contact. From this point it increased rapidly, and from 30° to 180° it was almost uniform.

If we separate the two unequal globes, a curious phenomenon takes place. At a certain distance, which is not great, the point of the little globe which was in contact with the larger globe, and which had no electricity, now shows *negative* electricity till they are farther separated. At a certain distance the electricity becomes again nothing, and at a greater distance the same point becomes *positive*.

When the large globe is eleven inches in diameter, and the small one eight, and both positively electrified, the point of the large globe which touched the small one is always positively electrified, whatever be the distance of the two. The similar point of the small globe, however, will be negatively electrified till the distance of the two is *one* inch, at which distance the electricity becomes nothing, and beyond it it becomes positive. If the small globe is only four inches in diameter, the same phenomena take place, but at the distance of two inches and five lines.

Several equal globes.

When *six* equal globes, two inches in diameter, were placed in one line in contact, and electrified, and then examined by the torsion balance, Coulomb found that the electrical density of the *first* was to that of the second as 148 to 100, and that of the *first* to that of the *third* as 156 to 100. When twelve similar globes were similarly placed, the density of the *first* was to that of the *second* as 150 to 100, and that of the *first* to that of the *sixth* as 170 to 100. When twenty-four similar globes were similarly placed, the electric density of the *first* was to that of the *second* as 156 to 100, and to that of the *twelfth* as 175 to 100. At equal distances from the extremities of the row the electric densities were equal, and the density always least in the middle.

A globe and a cylinder.

The last series of Coulomb's experiments which we shall notice at present, are the higly important ones relative to the distribution of electricity between a globe and cylinder. When the globe was *eight* inches in diameter, and the cylinder thirty inches long, he obtained the following results:—

Diameter of Cylinder.	Mean Electric Density of the Globe to that of the Cylinder.
24 lines	1 to 1·30
12	1 ... 2·00
2	1 ... 9·00

Hence the electrical densities of different cylinders are in the inverse ratio of the power $\frac{4}{5}$ths of their diameter, which approaches very much to unity when the diameter of the globe is very much greater than that of the cylinder.

Different globes and same cylinder.

When the globes are different, and the cylinders remain the same, the electric density of the cylinders will vary as the diameters of the globes, if their diameters are much greater than that of the cylinder. Hence, calling D the mean electric density of the globe, d that of the cylinder, R the radius of the globe, and r that of the cylinder, we have $d = \frac{mDR}{r^{\frac{4}{5}}}$ or $d = \frac{mDR}{r}$, when R is much greater than r. Coulomb found the constant co-efficient m to be $\frac{9}{48}$.

Sect. X.—*On the Action of Points, and on Electrical Rotations.*

Action of points.

The influence of points in silently drawing off electricity from a conductor has already been mentioned, and also their influence in discharging electricity from any conducting body in which they are fixed. Both these effects are distinctly seen if a person insulates himself by standing on a stool with glass feet, placed near an electrified prime conductor. If he takes in his hand a rod of metal with a ball at one end and a sharp point at the other, and holds the point at a certain distance from the conductor, he will be able to electrify himself in consequence of drawing the electricity from the conductor, whereas if he holds the ball at the same distance, he will receive no electricity at all. On the contrary, if he connect himself with the prime conductor by a chain till he is charged with electricity, and then throws aside the chain, he will not be able to discharge the electricity quickly from his body by holding out the ball, whereas if he holds out the rod with the point, the electri-

Phenomena and Laws.

city will be rapidly discharged from it, and will be seen streaming out from it in the dark.

Action of points explained.

The experiments contained in the preceding section afford a beautiful and satisfactory explanation of the action of points. We have already seen that the electricity communicated to a cylinder is so distributed that the electrical density of the extremity is 2·30, while that at the middle is 1; and that when the electrical density of a globe is 1, that of a cylinder two lines in diameter and thirty inches long is 9. But we may consider points as cylinders of small diameter and great length, and, following the result now mentioned, we shall find that the electrical density at the rounded extremity of a cylinder two lines in diameter will be $9 \times 2{\cdot}3 = 20{\cdot}7$, while that of the globe which the cylinder touches is only one. In order to make this plain, we have represented in fig. 7 a cylinder or rod AB, in which the ordinates of the curve M*c*N represent the electrical density at different points of the cylinder, or the thickness of the stratum of electricity at these points. The ordinate *cd* being 1, the ordinates AM and BN will be 2·3. But it may be shown, from the law of repulsion, that the re-action of the electric fluid upon the adjacent air varies as the square of the thicknesses of the electric strata, or as the squares of the electric densities. Hence the squares of the ordinates *cd*, AM, or 1, and $2{\cdot}30 \times 2{\cdot}30 = 5{\cdot}27$, will represent the re-action at *d* and A; that is, the electric fluid will have five times the tendency to escape at A, from what it has at *d*.

Plate CCXXIV., fig. 7.

Fig. 8.

When the point A is connected with a ball B, as in fig. 8, the tendency of the electric fluid to escape at A will be seen from the ordinates of the curve BM, the ordinate at A being very great. We have already seen that the ordinate AM, or the electrical density at A, is 20·7 times as great as the electrical density at B. Hence $20{\cdot}7 \times 20{\cdot}7 = 428{\cdot}49$ will represent the tendency of the electricity to escape from A, the tendency to escape from B being only one. But this tendency to escape is resisted by the air: and as the amount of resistance varies with the density, moisture, and temperature of the air, there will obviously be some degree of electrical density which will overcome that resistance. This result experience completely confirms, for even in the common state of the air a very great quantity of electricity is not necessary to make its way from a pointed conductor.

This tendency of points to discharge their electricity against the resisting air, enables us to perform some beautiful electrical experiments, in which a motion of rotation is effected.

Electrical rotation, fig. 9.

Exp. 1. If one, two, or any other number of wires are placed, as in fig. 9, so as to have beneath their centre of gravity, A, a hollow cup, which rests on the top of an insulated stand AB; and if the points *m*, *o*, *n*, *p* of these wires are made short, and are turned in the same tangential direction; then, if we connect them with the prime conductor by a chain C, so as to electrify them, the electricity will issue from each point; and as it will be resisted by the air against which it presses, the arms will turn round in a direction opposite to that in which the electric fluid is discharged, in the very same manner as the rotatory motion is effected in Barker's mill. In the dark a stream of light will exhibit the discharge of the electricity, and when the velocity of rotation becomes sufficiently great, the four streams will form a beautiful circle of light.

Electrical orrery, fig. 10.

Exp. 2. The *Electrical Orrery*, as it is called, is founded on the same principle. A spherical ball of metal S, fig. 10, representing the sun, has its inner concave surface supported on a pivot on the top of an insulated stand CD. From the ball S extends a wire SE, the turned-up extremity of which supports upon a pivot another ball E, which represents the earth, having a wire passing through it, and carrying at one end a small ball M, representing the moon, while the other end is bent into a sharp point *m*. A sharp point H is also fixed to the arm EF. If these balls are electrified as in the last experiment, by a chain A connecting them with the prime conductor, the discharge of electricity from the point H will give a rotatory motion to the arm CE and the earth E, while the electrical discharge from the point *m* will give a rotatory motion to the moon M round the earth E. In this manner the moon revolves round the earth, while the earth and moon are together carried round the sun.

Electrical bells.

Exp. 3. By the same principle a chime of bells may be rung in a more elegant manner than that which is exhibited in fig. 4, Plate CCXXII. Five cross arms of wire are made to revolve upon the pivot A of an insulated stand AB, as shown in fig. 11, and each wire has its extremity pointed and turned in the same direction. To one of these arms C, which is purposely made longer than the rest, is suspended a glass ball or clapper *b*, by a silk thread *ab*, and immediately behind it a rod CD. Eight bells are placed upon the stand, and if a chain connects the point A with the prime conductor, the discharge of the electricity from the points will move the cross arms round, and cause the clapper *b* to ring the bells during its revolutions.

Fig. 11.

Electrical inclined plane, fig. 12.

Exp. 4. The electrical inclined plane, shown in fig. 12, acts upon the same principle. Two straight parallel wires, MO, NP, are stretched upon the insulating stands M, N, O, P, fixed on a base of wood. Across these wires is placed a wire *ab*, having another wire *cd* at right angles to it, terminated by two bent points lying in a plane passing through *cd*, and at right angles to *ab*. When the apparatus is electrified by a chain, the electricity is discharged at the points *a*, *b* in a vertical plane, the wires revolve, and the wire *cd* rolls up the inclined plane, in opposition to the force of gravity.

Sect. XI.—*Explanation of the Phenomena of Electrical Attraction and Repulsion.*

Electrical attraction and repulsion.

In order to explain the phenomena of attraction and repulsion which have been already described, we must avail ourselves of several principles which have been either previously deduced from experiment, or which may be readily proved.

1. The electric fluid has a tendency to escape from all electrified bodies, whether conductors or non-conductors, in consequence of the mutual repulsion of its particles.

2. The electric fluid is prevented from escaping from bodies so rapidly as it would otherwise do, by the pressure of the air with which they are surrounded, and which is itself a bad conductor of electricity.

3. If the pressure of the air is increased, the escape of the electricity is diminished; and if the pressure of the air is diminished, the escape of the electricity is increased.

4. In *conductors* the electric fluid passes with the utmost facility and rapidity among the material particles, and does not seem to be in any way acted upon by them.

5. In *non-conductors* the electric fluid escapes from them, and moves among their material particles with difficulty; so that there is some force by which the electric fluid adheres to or is detained by the material particles of non-conducting bodies.

With the aid of these principles, we are now able to explain the three different cases of electrical attraction and repulsion.

Plate CCXXIV., fig. 13.

1. *When the two bodies are non-conductors.* Let A be a fixed electrified non-conducting body, and B another of the same kind capable of moving. The particles of the electric fluid in A will repel each other; but this repulsive force cannot produce any motion on the centre of gravity of the ball, as their united tendency is to produce rest. The same is true of the repulsive force of the electric fluid

Phenomena and Laws.

in B. Let us suppose that A and B are both electrified *positively*, or both *negatively*, then the repulsion between the electric fluid in A and that in B will cause B to recede from A, because the electric fluid in B adhering as it were to the particles of B, cannot recede from A without taking the body along with it. In like manner, if A is *positive* and B *negative*, or *vice versa*, the attraction of the positive electric fluid for the negative electric fluid will cause the electric fluid in the moveable body B to approach to that in A, and by its bringing the material particles along with it, will produce the phenomena of attraction.

Hence it follows that the attractions and repulsions of non-conducting bodies are produced by the attractions and repulsions of the electric fluid, which, from its adhesion to their matter, causes them to partake in its motion.

Figs. 14 & 15.

2. *When the one body is a non-conductor, and the other a conductor.* Let A, fig. 14 and 15, be a fixed and *non-conducting* body, and B a moveable and conducting body. When these two spheres are separate, the electric fluid is distributed on the surface of each in a stratum or thin shell of equal thickness; but when they are brought near each other, the fluid is distributed as in fig. 14, when A and B are *oppositely* electrified, and as in fig. 15, when they are *similarly* electrified; the space between the dark circles and the dotted outlines representing the section of the stratum of electrified fluid upon each sphere. The arrangement of the fluid in fig. 14 is produced by the attraction of the fluid in A for the fluid in B, and *vice versa*, producing an accumulation of it on each sphere on the sides nearest one another; and the arrangement of the fluid in fig. 15 is produced by the repulsion of the two opposite fluids, producing an abstraction of the fluid from the sides nearest one another, and an accumulation of it on the sides farthest from each other. But since the non-conducting sphere A is fixed, the adhesion of its fluid to its material particles cannot produce any motion; and since there is no adhesion between the fluid in the conductor B and its material particles, these particles, or the body which they compose, cannot move along with the fluid. The accumulated fluid, however, at the points O, O, figs. 14 and 15, tends to escape from the spheres in virtue of the mutual repulsion of its own particles; but it is restrained by the pressure of the air, which re-acts upon it. But the pressure of the air is an uniform force on every part of the sphere; and as the force with which the electric fluid resists this uniform pressure is greatest at the sides O, O, the ball B, in fig. 14, will recede in virtue of this force from A; and the ball B, in fig. 15, will from the same cause approach to A. The *attraction*, therefore, of the two *opposite* fluids in fig. 14 produces, through the agency of the atmosphere, a *repulsion* of the moveable sphere; and the *repulsion* of the *similar* electric fluids in fig. 15 produces, through the same agency, an *attraction* of the moveable to the fixed sphere.

Hence it follows that the attractions and repulsions of two bodies, one a conductor and the other a non-conductor, are merely apparent, and are produced solely through the agency of the atmosphere.

3. *When the two bodies are conductors.* In this case the phenomena will be nearly the same as in the last; for, by making A a conductor, we have only removed the adhesion between its fluid and the particles of which the body is composed, a force which was not brought into play in case 2, owing to A being fixed.

In the preceding observations we have taken no notice of the decomposition of the natural electricities of the two bodies, as the reader is not yet prepared for this consideration. We have supposed one of the spheres to be fixed and the other moveable, merely to simplify our illustrations; but it is obvious that the same effects would have been produced, but only with different degrees of intensity, if the two spheres had been moveable.

Phenomena and Laws.

In order to show that apparent attractions and repulsions may be produced by the mere resistance of the air, and without any mutual action between the particles of the two bodies which are attracted and repelled, M. Biot has employed a very happy illustration, on which we have ventured to make a slight improvement. Let B, fig. 16, be a glass globe filled with water, and suspended by a string A. Make a hole in two opposite points of it C and D, from which the water can flow, and having closed them with wax, fill the globe with water. With a burning mirror MN, whose focus is at C, condense the sun's rays RR, and melt the plug of wax at C. The water will instantly rush out, and the globe B will move away from M as if it had been repelled by the mirror. Repeat the same experiment by placing the mirror at M′N′, and throwing the sun's rays upon the opposite plug D by reflexion from the plain mirror *mn*. The plug D being melted, the water will flow out at D, and the globe B will approach to M, N, the mirror having appeared to repel the globe in the first case, and to attract it in the second, though the motion in both cases arises neither from attractive nor repulsive forces, but merely from an unbalanced pressure at D when the water flowed out at C, and an unbalanced pressure at C when the water was discharged at D.

Sect. XII.—*On Electrical Induction, or the Decomposition of the Combined Electricities by Actions at a distance.*

Electrical induction.

In the preceding sections we have considered the phenomena of electricity as produced by friction, and as communicated or transmitted by conductors to other bodies. But it has been found that electricity may be developed in bodies by the mere influence of an electrified body placed at a distance, and we shall now proceed to investigate the laws which regulate this interesting class of phenomena.

Plate CCXXV., fig. 1.

Let AB be a cylindrical conductor supported horizontally upon an insulating stand S, and having hemispherical ends at A and B. Suspend from the points A, B, C, D, E, F, similar pairs of pith balls attached to wires or linen threads, and, having insulated it carefully by the stand S, touch it with the finger in order to see that it contains no free electricity. Let an electrified sphere M be now brought near it, so that A, B, M are in the same straight line, and that no spark can pass from M to B. When this has been done, it will be observed that the pith balls diverge as in the figure, the divergency being a maximum at A and B, and equal at these points, becoming less at C and D, where it is also equal, and still less at E and F, where the equality of divergence still exists. Between E and F there will be found some *neutral point* where the pith balls exhibit no divergence, and this point will shift its position according to the distance of the electrified body M. If we now suspend an unelectrified pith ball by a silk thread, and bring it near to different parts of the cylindrical conductor, we shall find that it is attracted to it in all places except the *neutral point* between E and F.

This *neutral point* is never found in the exact middle of the cylinder between E and F. Its position varies with the distance of the body M, and with the intensity of its charge. In every case, however, it is nearer to the extremity B next the sphere M, than the distant extremity A.

From these experiments we are led to the important and curious result, that an *unelectrified body may be electrified by the influence of an electrified body acting upon it at a distance.* The electricity is in this case said to be *induced*, and the phenomenon is called *electrical induction.*

If we now electrify the pith ball which was suspended by a silken thread, and bring it near to the cylinder AB, we shall find that it is *attracted* by one half of the cylinder

Phenomena and Laws.

from A, for example, to the neutral point between E and F, and *repelled* by the other half from B to the same neutral point.

From this experiment we infer that *the electricity on one half of the cylinder, from one extremity to the neutral point, is* POSITIVE, *while the electricity in the other half is* NEGATIVE.

Bring the electrified pith ball near the electrified body M, and it will be found that, if it was formerly repelled from B, it will be attracted by M, and *vice versa;* so that we conclude that *the electricity induced upon the half of the cylinder nearest the electrified body is always opposite to that of the electrified body.*

If we now measure the electricity of the body M, both before and after the preceding experiments, and make allowance for the dissipation of it through the agency of the adjacent air, we shall find that no part of its electricity has been communicated to the cylinder AB; and if, while the cylinder AB is electrified by the inductive influence of M, we either remove M to a distance, or discharge its electricity by touching it with the finger, the electricity of the cylinder AB will instantly disappear. In like manner, AB will recover its electrical state the moment that M is brought near it.

Hence it follows that *the positive and negative electricities developed in a conducting body by the presence of an electrified body are not communicated to it by that body, but have existed in a state of combination in the substance of the conductor, and have only been separated from their state of combination by the action of the electrified body.*

As the intensity of the *positive* electricity, as well as its quantity, is the same in one half of the conductor as that of the *negative* electricity is in the other half, and as there is no remaining or *free* electricity in the cylinder AB when the body M is withdrawn, it follows that the union or recombination of the two electricities has neutralized or saturated each other. But as the two united electricities have not been destroyed by their union, they exist in a new state, which is called the *natural electricity* of bodies. The electricity, therefore, which thus naturally resides in conductors, consists of equal quantities of *positive* and *negative* electricity, which neutralize each other's action, and are consequently incapable of producing any of the phenomena of *free* electricity, or of a portion of positive or negative electricity existing in a separate state.

With these explanations, we are now able to understand how the cylinder AB is electrified by the influence of the electrified body M. We have clearly proved, by direct experiment, that bodies similarly electrified repel each other, while bodies oppositely electrified attract each other; and we have shown in Section X. that this repulsion and attraction does not take place between the material particles of the bodies, but between their electricities, or the electric fluids which they respectively contain. Hence we may enunciate the law in the following manner:—*Similar electricities repel each other, and dissimilar electricities attract each other.* Now when the sphere M, which we shall suppose to be electrified *positively*, is brought near the cylinder AB, in which the electricity exists in its natural or combined state, it will repel all the *positive* electricity, and attract all the *negative* electricity, overcoming the tendency which each has to diffuse itself in virtue of the mutual repulsion of its own particles, and the tendency which the two opposite electricities have to recombine by their mutual attraction. Hence all the *negative* electricity will be *attracted* to and occupy the half FB of the cylinder, and all the *positive* electricity will be *repelled*, and occupy the remoter half EA. If M is *negatively* electrified, the opposite effects will be produced. Let the body M be now withdrawn, the repulsive and attractive forces which it exercised upon the natural electricity of AB will cease, and the two electricities, separated by its action, will recombine by their mutual attraction, as well as by the mutual repulsion of the particles of each, and the cylinder AB will be restored to its natural state of electricity.

Electrical attraction explained.

The principle of electrical induction which we have now illustrated enables us to give a satisfactory explanation of the phenomena of attraction which have been described in Section II. It was there shown that electrified bodies attracted light and unelectrified bodies that were brought near them; but it will now appear that these apparently unelectrified bodies were first electrified by induction, and, in consequence of the decomposition of their natural electricities, were attracted by the excited body. Thus, if M (Plate CCXXV., fig. 1) is an electrified body placed in a perfect vacuum, and AB a small light body suspended near M, and capable of moving towards it, then AB will be so electrified by the influence of M, that the electricity of the same name as that of M will be accumulated in the half FB of the cylinder, and the other electricity in the half EA. But the electricity of M attracts that of BF more powerfully than it repels that of EA, and consequently the light body AB will be attracted to M in consequence of the previous decomposition of its native electricity. If this decomposition cannot be effected by M, or if it takes place with difficulty, the body AB will not be attracted, or will be attracted less readily.

Plate CCXXV., fig. 1.

Biot's experiment.

M. Biot has illustrated this position by the following simple experiment. Suspend by fine silk threads two small balls of equal dimensions, one of them being made of pure gum-lac, and the other of gum-lac either gilt on its surface or covered with a thin plate of tinfoil. When these two balls are placed beside each other, and at a small distance, bring near them an electrified tube of glass or sealing-wax, and it will be seen that the gilt ball will be more strongly and easily attracted than the other. The uncoated ball of lac will not begin to be attracted till after a certain time, when the decomposition of its natural electricity has been effected; and thus its electrical state will continue after the removal of the electrified body. The first ball, though gilt, acquires also in this manner a permanent electricity, because the gum of which it is composed is impregnated with the electricity developed at its surface, and both of them are in this respect assisted by the contact of the air, which, under the influence of the electrified body, tends especially to carry off from them the one of the two electricities, which is repelled by this body, while it has less effect upon the other, whose proper repulsive force is concealed by attraction. Hence, says M. Biot,[1] we observe in general, that insulated bodies which have for some time been under the influence of an electrified body, end in having an excess of electricity of a kind opposite to its own, and the effects of which are seen when they are withdrawn from the influence of that body.

In examining the action of M upon AB, fig. 1, we supposed that no change took place in the electrical condition of M; but this is not the case, for the body AB, as soon as its natural electricity has been decomposed, begins to re-act upon M, through the agency of its separated electricities. These separated electricities not only tend by their attractive and repulsive forces to change the distribution of the free electricity which exists in M, but also to decompose its natural electricity, and thus to increase its free electricity by one of the two separated electricities. When this change has been effected upon the electrical state of M, its action upon AB will also change. It will decompose a new quantity of the natural electricity of AB, and distribute the positive and the negative electricities of which it is composed in the halves AE, BF; and these new portions will again re-act upon M, till a permanent equilibrium is effected

[1] *Traité de Physique*, tom. ii., pp. 283–4.

Phenomena and Laws.

among all the attractive and repulsive forces which are thus brought into play.

Supposing such an equilibrium to be established between the two bodies M and AB, we shall proceed to examine the phenomena which are produced by the introduction of a third body. For this purpose let AB represent the conducting cylinder, and M the electrified body, as in fig. 2. Let an insulated conducting body O, in its *natural state* of electricity, be now brought near AB, so as to touch it, and let us suppose that the electricity of M is *positive*, and consequently that the electricity in the half BE is *negative*, and that in AE *positive*. If we now remove the body O, and examine its electrical state, we shall find that it has acquired *positive* electricity, and we shall observe that the divergency of the pith balls at A has diminished, while their divergency at B has increased. If we again remove the cylinder AB from the influence of M, or remove M from it, we shall find that AB is charged with *negative* electricity. Previous to the contact of O with A, the *positive* electricity in AE repels the *negative* electricity in M, and attracts the *negative* electricity in BE. Hence it contributes by both these actions to weaken the attraction of the *positive* electricity in M for the *negative* electricity in BE, and its repulsion for the positive electricity in AE. But when, by the contact of the third conductor O with the end A of AB, we withdraw a portion of the positive electricity in AE, we at the same time increase the attraction between M and BE, and the repulsion between M and AE, by diminishing the force by which that attraction and repulsion were weakened. Hence the increased action of M will decompose an additional portion of the natural electricity of AB, drawing the *negative* part of it to EB, and repelling the *positive* part of it to AE. The electricity, therefore, which is accumulated at B or in EB is greater than that accumulated at A or in EA, because the third conductor O has taken away a part of the positive electricity in AE. Hence, when we remove AB from the influence of M, so as to allow its separated electricities to re-combine, there is an excess of negative electricity, with which of course AB will be found charged. It is therefore obvious that the divergency of the balls should be greater at B than at A, as was found to be the case from the excess of *negative* electricity which existed at B while the cylinder was under the influence of M.

Plate CCXXV., fig. 2.

In the experiment, as above described, the third conductor O was insulated, and could therefore carry off only a portion of the positive electricity in AE, corresponding to its size: but if we use a conductor which communicates with the ground, the whole of the free electricity in AE will escape; the pith balls at A will exhibit no divergency, while those at B will diverge still more than they did formerly; and this divergency will suffer no diminution by again touching the end A with the insulated conductor. If the conductor AB is now removed out of the influence of M, the divergency of the balls at B will be still further augmented. The cause of these phenomena is very obvious. When all the positive electricity in AE has escaped into the earth, it no longer counteracts the action of M upon BE, so that this action is augmented; and the consequence of this is, that M decomposes a fresh portion of the natural electricity of AB, the positive part of which passes off, by the mutual repulsion of its own particles, into the earth, while the resinous part is collected in BF, and increases the divergency of the balls at B. Hence, when AB is removed from the influence of M, the excess of *negative* electricity will be greater than previously, and the divergency of the balls at B will increase conformably with observation. The very same phenomena will be observed if the body M is charged with *negative* electricity, and may be described in the very same words by changing only the terms *positive* for *negative* and *negative* for *positive*.

The subject of electrical induction, on which Coulomb had thrown so much light, has been recently studied by M. Mohr, a German philosopher. Having insulated a cylinder AB, Plate CCXXV. fig. 1, 65 centimeters in length, he placed a positively electrified body M at the distance of 1 centimeter from the extremity B. In this case the *neutral* point was found at the distance only of 1 centimeter from B, so that the negative electricity occupied only 1 centimeter in length of the surface of the cylinder, while the *positive* electricity occupied 64 centimeters. By *increasing* the distance of M from B, or by diminishing the charge of M, the space occupied by the *negative* electricity would have been *increased*, and that occupied by the *positive* diminished, the former, however, being always inferior to the latter.

In making experiments of this kind, great care must be taken to prevent any of the electricity of the charged sphere M passing into the insulated conductor, either by the moisture of the intervening air, or the shortness of the intervening space.

If we connect AB with the earth, after removing it from the sphere M, it will be found charged with an excess of the electricity opposite to that of M.

In all these experiments on induction, the charged sphere M, the inducing body, suffers no loss of electricity from having exercised its inductive action.

CHAP. II.—ON THE ELECTRICITY PRODUCED BY HEAT, PRESSURE, AND SEPARATION OF PARTS.

In the preceding chapter we have given a general and popular view of the phenomena of electricity, and we have explained the remarkable phenomena of electrical induction. In our experiments and observations on these subjects we have made use of the electricity which is generated by the friction of tubes of glass or sticks of sealing-wax, or which is obtained from the common electrical machine. But electricity can be obtained from various other sources, and its properties are the same, from whatever source it is obtained, provided it is used in the same quantities and of the same intensity.

As there is no part of the science more interesting to the general reader than that which relates to the different modes in which electricity can be obtained from organized and unorganized bodies, we shall enter fully into this branch of the subject, and shall treat, in successive chapters, of the electricity produced by heat and pressure, by change of form and separation of parts, by animal bodies, and by the elements of our atmosphere.

SECT. I.—*On Pyro-electricity, or the Electricity produced in Minerals by Heat.*

Pyro-electricity.

In our history of the science we have already given a general view of the progress of discovery in this interesting branch of electricity. We shall now, therefore, proceed to describe the phenomena which are developed by heat in various minerals and artificial salts.

1. *On the Pyro-electricity of Tourmaline.*

Tourmaline.

The tourmaline is a very common mineral, which crystallizes in long slender prisms. Its primitive form is an obtuse rhomb, the axis of which coincides with the axis of the prism. It has also one negative axis of double refraction, which is coincident with the axis of the rhomb; and it possesses some remarkable properties in reference to the absorption of common and polarized light, which will be described in another article. This mineral acquires *vitreous* electricity by friction; and when two tourmalines are rubbed

Phenomena and Laws.

together, the one acquires *vitreous* and the other *resinous* electricity.

In order to observe the electricity which heat developes in certain minerals, we have found it convenient to use the thin internal membrane of the *Arundo Phragmites*, which was cut with a sharp instrument into the smallest pieces, or, what is still better, the thin transparent scales which cover the buds of several plants of the genus *Pinus*, and which are pushed off at the expansion of the bud in spring. These minute fragments are well dried, and the pyro-electricity of any mineral is determined by its power of lifting one or more of these light bodies after the mineral has been exposed to heat. When we wish, however, to determine the kind of electricity which is developed in any pole of a mineral, we must employ a small instrument, called an electroscope, such as that used by Haüy, which is shown in Plate CCXXV., fig. 3, where AB is a needle of silver or brass, terminated on one side by a globule B of the same metal, and on the opposite side by a small bar or narrow plate G of transparent Iceland spar, fixed to A by wax or any other means. This needle carries at its middle point D a cup of rock-crystal (garnet is preferable), by which it rests on a steel pivot at the upper end of the piece of wire D, fixed in a cylinder E of gum-lac or sealing-wax. A small weight G is made to move along the arm BD to balance the needle in a horizontal position. In order to prepare this little instrument for observation, take the lever by the end B, with the right hand, and with two of the fingers of the left hand press two of the opposite faces of the crystal G, and then place the lever upon its pivot D. Haüy calls this apparatus a *vitreous* or *positive* electroscope.

Haüy's vitreous electroscope. Plate CCXXV., fig. 3.

The *resinous* or *negative electroscope*, which is shown in Plate CCXXV. fig. 4, differs from the preceding only in having a simple needle of silver or copper AB, with two globules A, B at its extremities, and having a cup C of the same metal. In order to prepare this electroscope for use, a stick of sealing-wax is rubbed with a piece of woollen cloth, and then made to touch one of the globules of the needle, which is immediately repelled.

Haüy's resinous electroscope, fig. 4.

In order to determine the kind of electricity generated in any pole of a crystal by heat, we have only to apply it to either of these electroscopes. If it attracts the globule of the vitreous electroscope, or repels that of the resinous one, its electricity will be resinous; and if it repels the globule of the vitreous one, and attracts that of the resinous one, the electricity will be vitreous.

Haüy's general apparatus, fig. 5.

Haüy used another apparatus in his experiments with tourmaline, which he considers preferable to all others. A rectangular plate of metal *hk*, bent up at right angles at its two ends *h*, *k*, is balanced on a steel needle *ab* by a cup of agate *x*, which is confined by a circle of silver and two screws *s*, *z*. Towards the extremities of the lower surface of the plate *hk* are fixed two silver wires *pi*, *uy*, having a slightly oblique direction, and terminated by two silver globules *i*, *y*. The use of these little balls is to lower the centre of gravity of the apparatus, so that the plate *hk* may always remain supported during its revolution on the pivot. Let us now suppose that we wish to determine the two kinds of electricity which exist in the poles of a tourmaline. Take one of the Spanish crystals, which is the best for the purpose, both from their thinness and their strength, and having heated it either at the fire or at the flame of a spirit-lamp, by holding it in a pair of iron pincers with a wooden handle, place it at *mn*, as shown in fig. 5, in the two notches made on purpose in the bent-up pieces *h*, *k*; and having held near its poles in succession a stick of excited sealing-wax, that pole, *v*, will be the *vitreous* one which is attracted by the wax, and the other, *r*, the resinous one which will be repelled by it.

After measuring the intensity of the electricity in different points of the tourmaline, Haüy found that the electricity was distributed nearly in the same manner as in a cylindrical conductor electrified by induction. The *vitreous* electricity was a maximum near one extremity of the crystal, and gradually diminished towards the middle of the crystal, where it disappeared. Here the *resinous* electricity appeared very faintly, and gradually increased towards the other end of the crystal, near which it was a maximum.

If tourmaline, when rendered electrical by heat, is broken in pieces, each piece will have a vitreous and a resinous pole, whether it is broken from the vitreous or the resinous end, the extremity of the fragment always possessing the same kind of electricity as that of the pole to which it was nearest when it formed part of the crystal.

Influence of heat.

It had been early noticed that the tourmaline became electrical only at a particular temperature, and that its electricity disappeared at temperatures above and below that particular degree of heat. If we heat the tourmaline beyond this temperature, and allow it gradually to cool, it will soon arrive at that temperature (between 30° and 80° of Reaumur, 99° and 212° of Fahr. according to Æpinus) at which it exhibits its electrical properties. As the temperature falls, its electricity becomes progressively feebler, and finally disappears. Haüy, however, found that other changes take place as the cooling of the mineral increases. At a certain degree of coldness its electricity re-appeared, and gradually increased till it reached its maximum, when it again disappeared gradually. But, what was very interesting, the electricity was not the same as before; the pole which was formerly *vitreous* was now *resinous!* [1] It is extremely probable that the same changes would continue to take place both above and below the temperatures at which these two opposite states were produced. Haüy caused the foci of two burning-glasses to fall upon the poles of a tourmaline, and he observed that, after each pole had acquired its electricity, it then ceased to act, and finally exhibited an electricity of an opposite kind.

Haüy has ingeniously explained the phenomenon of each fragment of a tourmaline having two different poles, like the crystal to which it belonged, by supposing that every integrant particle of a tourmaline is itself a little tourmaline with its two poles. "Hence it follows," says he, "that in the entire tourmaline there will be a series of poles alternately vitreous and resinous; and such are the quantities of free fluid which appertain to these different poles, that in all the half of the tourmaline yet unbroken, which manifests the vitreous electricity, the vitreous poles of the integrant molecules are superior in force to the resinous poles in contact with them; while the contrary obtains in the half which manifests the resinous electricity; whence it follows that the tourmaline is in the same state (speaking generally) as if each of its halves were only solicited by quantities of vitreous or resinous fluid equal to the differences between the fluids of the neighbouring poles. Now, if the stone be cut at any place whatever, as the section can only take place between two molecules, the part detached will necessarily commence with a pole of one kind, and terminate with a pole of a contrary nature."

Experiments of Sievright and Æpinus.

Mr Sievright of Meggetland fitted up a tourmaline so as to bring the action of its two poles very near each other. It resembles the letter D with an opening in its round part, the straight line representing the tourmaline, and the two bent portions are pieces of silver wire rising out of two silver cups, one of which embraces each pole of the tourmaline. If a pith ball, or a ball of sola, is suspended between the two ends of the silver wires, it will vibrate in a beautiful manner, in virtue of their opposite actions. Æpinus, it appears, fitted up the tourmaline in a manner somewhat re-

[1] This inversion of the poles was discovered by Mr Canton.

Phenomena and Laws.

sembling that which has been described. Sir Humphry Davy has stated the curious fact, which we believe has never been verified by any subsequent observer, that "when the stone is of considerable size, flashes of light may be seen along its surface."[1]

On the Pyro-electricity of thin Plates of Tourmaline.

Pyro-electricity of thin plates of tourmaline.

The electricity exhibited by ordinary crystals of tourmaline is very feeble; and though two good tourmalines, when floated in water upon corks, will approach and recede from each other when they are excited by a suitable temperature, yet these tourmalines are not capable of lifting one another, or of adhering to an unelectrified body, by decomposing the natural electricity of the part of it with which they are brought in contact.

A method of increasing the electrical action of tourmaline, and of enabling one large piece to lift another, and even to adhere to other bodies, has been used by Sir David Brewster. He cut thin slices out of a large crystal of tourmaline so that they had parallel faces perpendicular to the axis of the original crystal, as represented in fig. 6, where VVVV is the vitreous face of the plate, corresponding to the vitreous pole of the crystal; and RRRR the resinous face; each of these faces being perpendicular to the edge VR of the prism, and consequently to the axis of the crystal. When the two faces of the plates thus formed are ground flat and well polished, one plate will readily lift another. If we place one of these plates upon a piece of flat plate glass, placed horizontally upon a table, the tourmaline will slip off the glass if the latter is slightly inclined to the horizon. But if the glass has been previously heated, the tourmaline plate will adhere to it; and by inverting the glass, the tourmaline will adhere to it even in that position, supporting its own weight by its attraction for the glass. The intensity of the electricity may be easily measured at different temperatures, by ascertaining the angle of inclination at which the weight of the tourmaline overcomes its adhesive force. The plate which exhibits this powerful action obviously consists of an infinite number of minute crystals of tourmaline, with vitreous and resinous poles; and as the point of maximum intensity is situated near the extremity of each crystal, all the vitreous poles will be situated in a plane near the vitreous surface VVVV, while all the resinous poles will be situated near the resinous surface RRRR. If a rectangular plate of the same size, like VVRR, fig. 7, is cut out of a crystal, so that its surfaces are parallel to the axis of the prism, it will adhere to the heated glass plate with much less force than in the preceding case. These plates of excited tourmaline adhere to all metallic bodies, to wax, and to all minerals that have been tried.[2]

Plate CCXXV., fig. 6.

If there was no mistake in the experiment by Sir H. Davy, described in a former paragraph, respecting the appearance of a flash of light in a mounted tourmaline, it will doubtless be best verified by mounting several plates of equal thickness, cut out of a broad tourmaline, placing them all in the same plane, and combining their effects in two wires. A powerful little pyro-electrical battery might thus be made, from which both a shock and a flash might be obtained.

Having found that the electricity of plates of tourmaline was more powerful than crystals of it, Sir David Brewster conceived the idea of examining its pyro-electricity, when its fragments were infinitely small, or when it was reduced to the finest powder or dust. The analogy of magnetic bodies led to the notion that the pyro-electricity would disappear, while the results obtained with short prisms in the form of plates strengthened the opposite opinion, that the pyro-electricity might even be increased by this process. I therefore "pounded, he says, a portion of a large opaque tourmaline in a steel mortar till it was reduced to the finest dust. I then placed the powder upon a plate of glass, from which it slipped off by inclining the glass, like all other hard powders, without exhibiting any symptoms of cohesion, either with the glass or with its own particles. When the glass was heated to the proper temperature, the powder stuck to the glass; and when stirred with any dry substance, it collected in masses, and adhered powerfully to the substances with which it was stirred. This viscidity, as it were, or disposition to form clotted masses, diminished with the heat, and at the ordinary temperature of the atmosphere it recovered its usual want of coherence."[3]

M. Becquerel made some interesting experiments on the pyro-electricity of the tourmaline. He found that when the crystal was of a certain length it became electrical both by heating and cooling; and that crystals of a greater length ceased to become electrical by heating. When the length of the crystal was eight centimeters, or three inches and one ninth of an inch long, they ceased to exhibit electricity either by heating or cooling. M. Becquerel remarks, that if this law is inversely true, that is, for very small lengths, *the atoms of the tourmaline ought to acquire a considerable electrical polarity by the smallest changes of temperature.*[4]

2. *On the Pyro-electricity of the Borate of Magnesia.*

Borate of magnesia.

The electricity developed in boracite by heat is considerably less than that of the tourmaline. In 1791 the Abbé Haüy discovered the pyro-electricity of this mineral; but he found it extremely difficult to determine the vitreous and resinous poles. He naturally expected to find two opposite poles, as in the tourmaline; but a succession of attractions and repulsions which took place very rapidly perplexed him extremely. Considering, however, that the boracite was a cubical crystal with three axes, and the tourmaline a rhombohedral one with only one axis, he conceived that the former crystal has a vitreous pole at the one end of each axis, and a resinous pole at the other end. This conjecture he verified by experiment; and the poles were found to be so placed that each alternate pole possessed the opposite electricity; the experiments, however, which are necessary to establish this result require to be made with great care, particularly in reference to the repulsive actions, which take place only within a very limited space; so that, in order to obtain the repulsion of one of the resinous poles on a body which is itself in a resinous state of electricity, we must direct this body exactly to the repulsive point, otherwise it will be attracted towards the neighbouring points, which are in their natural state, or nearly so.

It is a curious fact, in reference to the preceding results, that the boracite has been found by Sir David Brewster to possess distinct double refraction; and consequently it cannot, as he concludes, have the cube for its primitive form, or three axes of crystallization. He infers that its primitive form is a rhombohedron of ninety degrees, the form which separates the obtuse and acute rhombohedrons; and hence it is a most remarkable circumstance that its electrical poles should be arranged in the manner described by Haüy.

3. *On the Pyro-electricity of the Topaz.*

Topaz.

The pyro-electricity of the Brazilian topaz was discovered in by Mr Canton in 1760. The Abbé Haüy detected the same property in the topaz of Siberia, and found that the poles resided in the two opposite summits of the secondary form of the crystal. Haüy at first thought that the Saxon topazes did not possess pyro-electricity, although they often preserved excited electricity for more than half

Phenomena and Laws.

an hour when the weather was favourable. He afterwards found, however, that they became electrical by heat if previously insulated. Sir David Brewster found pyro-electricity in the greenish-blue topazes of Aberdeenshire.

A pyro-electric rotation of a very extraordinary kind was observed by Sir David Brewster in a specimen of topaz. It presented itself when he was studying the very interesting collection of crystals in the cavity AB. This cavity is filled with the dense fluid which is frequently found in topazes,

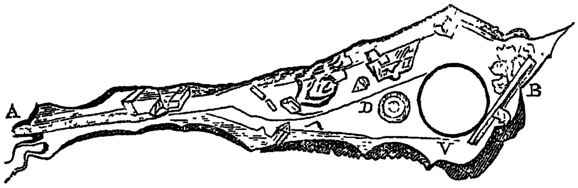

Fig. 5.

in contradistinction to the highly expansible one which often accompanies it. The circle at V represents a vacuity in the fluid, which diminishes so perceptibly by the expansion of the fluid when heated, that there is reason to believe that it would disappear by an increased degree of heat, like the vacuities in the expansible fluid. The fear, however, of bursting so rare and interesting a cavity, prevented the experiment from being made. The cavity AB contains a great number of crystals of different forms, not one of which melts with heat like some of those in other cavities, and almost all of them possess double refraction. When this cavity was first placed under the microscope there were five small crystals lying between D and the vacuity V—one a flat prism, a second a hexagonal plate, a third an amorphous crystal, and a fourth and fifth two irregular halves of a hexagon. *Upon the first application of heat one or two of these crystals leapt from their places, and darted to the opposite side of the cavity.* In a few seconds the others quitted their places one after another, *performing the most rapid and extraordinary rotations;* one crystal joined another, and at last four of them thus united revolved with such rapidity, that their respective shapes were completely effaced. They afterwards separated on the withdrawal of the heat, and took the position which their gravity assigned them. On another occasion a long flat prism performed the same rotation round its middle point; and, on showing the phenomenon to different persons, the experiment was so often repeated that the small crystals have been driven between the inclined edges of the cavity so that they cannot be extricated. A fine octahedral crystal, however, truncated in its edges and angles, was afterwards conducted into the middle at D, where it performed its rotations as indicated by the concentric circle at the right hand of D. In subsequently applying a high degree of heat the cavity burst, and scattered its microscopic contents.[1]

Haüy observed that the Siberian topazes often preserve their pyro-electricity during several hours, and sometimes from *twenty* to *twenty-four* hours.

Among some topazes which Haüy received from M. Langsdorf, there was one which exhibited resinous electricity at both of its poles, and indications of vitreous electricity in the middle of the crystal. This effect was probably owing to one or more strata of cavities containing fluids, which may have interrupted the distribution of the electricity in the same manner as a fissure.

4. *On the Pyro-electricity of Mesotype.*

Mesotype. Haüy discovered that some crystals only of this mineral were electrical by heat; but as he was not able to obtain complete crystals he detached from its support one about five and a half lines long, and found the pyramidal summit to be resinously electrified. *Mem. Instit.*, tom. i., p. 54–55. In the first edition of his Mineralogy, however (vol. iii., p. 168), he states that the pyramidal summit exhibits *vitreous* electricity by heat, and the fractured end *resinous* electricity; but in the *second* edition of his mineralogy he has omitted altogether that passage, and said nothing whatever on the subject.

The mesotype of Haüy's first edition included the Auvergne mesotype, the apophyllite, the scolezite, and the nadelstein; and therefore it is difficult to say to which of these minerals his observations are applicable.

Sir David Brewster found distinct pyro-electricity in the mesotype of Auvergne.

5. *Pyro-electricity of the Scolezite.*

Scolezite. The scolezite is a compound crystal, in which the faces of composition are parallel to the axis of the prism. Sir David Brewster found it to possess pyro-electricity, the pyramidal summit having vitreous, and the fractured end resinous electricity.

6. *Pyro-electricity of Mesolite.*

Mesolite. The mesolite, which has been separated from the scolezite both by distinct chemical and optical characters, is distinguished still further by its being composed of four simple crystals, whose faces of composition are parallel to the axis of the prism, whereas the scolezite consists of two prisms separated by a thin film or vein. Sir David Brewster likewise observed the pyro-electricity of this mineral, and found that its crystallized summit possessed vitreous electricity, and its fractured end resinous electricity, when heated.

7. *On the Pyro-electricity of the Powders of Scolezite and Mesolite when deprived of their Water of Crystallization.*

Powders of Scolezite and Mesolite. In the experiments above recited on the powder of tourmaline, the mineral had suffered no other change by trituration than that of being reduced to minute fragments. It became interesting therefore to compare the pyro-electricity of such a powder with that of the powder of a pyro-electrical mineral on which an essential chemical change had been induced. With this view Sir David Brewster reduced to powder the crystals of scolezite and mesolite, and by the application of heat drove off their water of crystallization, which is doubtless an essential ingredient in every mineral species. When the powder was exposed to a proper heat on a plate of glass, it adhered to it like the powder of tourmaline; and when stirred about by any substance whatever, it collected in masses like new-fallen snow, and adhered strongly to the body which was used to displace it. "This fact," says Sir David Brewster, "is a very instructive one, and could scarcely have been anticipated. As several minerals differ only in the quantity of their water of crystallization, the powder which was thus pyro-electrical could not be considered either as scolezite or mesolite, but as another substance not recognised in mineralogy. The pyro-electrical property, therefore, developed by the powder, cannot be regarded as a property of the minerals of which the powder formed a part, but merely as a property of some of their ingredients. In which of the ingredients, or in what combination of them, the pyro-electricity resides, may be easily determined by further experiments.

8. *Pyro-electricity of Axinite.*

Axinite. In his *Manual of the Mineralogist and the Geological Traveller*, M. Braard has stated that some crystals of this mineral become electric by heat. Haüy has confirmed this observation, but no accurate experiments on the position and electricity of its poles have been made.

[1] See *Edinburgh Transactions*, 1845, vol. xvi., part i., p. 19; or *Phil. Mag.*, Dec. 1847, vol. xxxi., p. 497.

Phenomena and Laws.

9. *Pyro-electricity of Calamine.*

Calamine. So early as 1785 M. Haüy discovered the pyro-electricity of this mineral, which being an oxide of zinc, is the more remarkable, as it is the only metallic body in which this property is very distinctly developed. Haüy found that every crystallized specimen which he tried was pyro-electrical, and that it acquired this property also by cooling. His first observations on the return of the electric action were made on the crystals of oxide of zinc from Limbourg, near Aix-la-Chapelle; and a portion of the acicular variety from the Brisgau. In the winter of 1819 he placed a crystal on a window where the temperature was 11 degrees Cent. below zero, and having left it there a few seconds he found that it acted very sensibly on a magnetic needle not insulated. He next placed it in a room whose temperature was four degrees above zero, and he observed that its polar action progressively diminished and disappeared. He then brought it within a yard of a fire, and had the satisfaction of observing its polarity return, the pole which was formerly vitreous being now resinous.

10. *Pyro-electricity of Sphene.*

Sphene. Haüy has found that some crystals of this mineral possess pyro-electricity, but he has not determined the position or nature of its poles.

11. *Pyro-electricity of Prehnite.*

Prehnite. This mineral crystallizes in right rhomboidal prisms. Haüy found it to be pyro-electrical, and that its poles are in a direction corresponding with the smaller diagonal of the crystal.

12. *Pyro-electricity of other Minerals.*

Other minerals. The property of becoming electrical by heat has been found by Sir David Brewster to exist in a great number of minerals; and he has given the following list of those in which he succeeded in detecting it:

Calcareous spar.	Yellow orpiment.
Beryl yellow.	Analcime.
Sulphate of barytes.	Amethyst.
Sulphate of strontites.	Quartz, Dauphiny.
Carbonate of lead.	Idocrase.
Diopside.	Mellite?
Fluor spar red.	Sulphur native.
Fluor spar blue.	Garnet.
Diamond.	Dichroite.

13. *Pyro-electricity of artificial Crystals.*

Artificial crystals. In examining the physical properties of artificial crystals, Sir David Brewster found that several of them, when well dried, were electrical when heated. The following is the list of those in which he detected this property.[1]

Tartrate of potash and soda.	Sulphate of magnesia.
Tartaric acid.	Prussiate of potash.
Oxalate of ammonia.	Sugar.
Oxymuriate of potash.	Acetate of lead.
Sulphate of magnesia and soda.	Carbonate of potash.
Sulphate of ammonia.	Citric acid.
Sulphate of iron.	Oxymuriate of mercury.

Oxalate of lime. Dr Faraday[2] has more recently discovered a remarkable degree of pyro-electricity in oxalate of lime. Having obtained some of this salt by precipitation, and dried it, when well washed, in a Wedgewood's basin, at a temperature of about 300° Fahr. till it was so dry as not to dim a cold plate of glass held over it, Dr Faraday remarked that, when it was stirred with a platina spatula, it became in a few moments so strongly electrical that it could not be collected together, but flew about the dish whenever it was moved from its sides into the sand-bath. This phenomenon took place whether the salt was placed in glass, porcelain or metallic basins, or stirred with glass, porcelain, or metallic rods. When the particles were well excited and shaken on the top of a gold-leaf electrometer, the leaves diverged two or three inches. The same phenomena took place when it was cooled out of the contact of air. When it was excited in a silver capsule, and left out of contact with the air, the powder continued electrical for a great length of time, proving its very bad conducting power, in which it probably surpasses all other bodies. Dr Faraday remarks, that oxalate of lime stands at the head of all other bodies yet tried, in its power of becoming positively electrical by heat.

14. *On the connection between the Pyro-electricity of Minerals and their Secondary Forms.*

It is well known that the opposite and corresponding sides of crystals are similar in the number, disposition, and figure of their faces. Haüy, however, found that pyro-electrical crystals deviate from this symmetry, so that there are certain supernumerary planes at one pole which are not seen at the other. This is true of tourmaline, boracite, topaz, and axinite, and may possibly be found to be a general fact among pyro-electrical crystals, though we do not expect that it will. In the crystals above mentioned, the vitreous electricity resides in that pole where the supernumerary planes are found, and the resinous electricity in the other.

This deviation from symmetry as existing in the tourmaline is shown in fig. 8, where A is the vitreous pole at the summit of a pyramid with *five planes*, and B the resinous pole at the summit of a pyramid with *three planes*. Plate CCXXV., fig. 8.

The deviation from symmetry in the boracite is more remarkable. The resinous pole at *s*, fig. 9, is marked with one plane, while the vitreous one has the same plane *s* with other three planes *rrr*, fig. 10. Plate CCXXV., fig. 9; fig. 10.

From the preceding facts, Haüy is of opinion that, during the formation of these crystals, the two electrical fluids have influenced, in an opposite manner, the laws by which the crystallization was regulated.

SECT. II.—*On the Influence of Heat upon the Electric Fluid in Metallic Bodies.*

The experiments which have been made on this subject we owe chiefly to M. Becquerel, of whose labours we shall endeavour to give a brief account. It had been long ago shown by M. Desaignes that metallic bodies are capable of electric excitation by heating and cooling. By raising the temperature o. one end of a plate of silver, while the other retained the temperature of the surrounding air, he succeeded in producing contractions in a frog, by making the nerve communicate with one end of the plate, and the muscle with the other end. Other philosophers had observed the influence of heat, and they believed that it increased the repulsive force of each of the two fluids. In proof of this they sealed hermetically at a lamp a tube of glass which had been previously electrified interiorly, and by raising its temperature it gave very distinct signs of electricity. M. Becquerel, however, has remarked, that the glass, becoming a better conductor when heated, allowed a portion of the fluid accumulated in the interior of the tube to pass; so that the experiment does not prove that the electrical power of the tube was increased. In order to determine if any does take place, M. Becquerel made the following experiment. Influence of heat.

Let AB, fig. 11, be a Leyden jar, on the surface of which is fixed a conductor RS. The jar is closed by a cork *gg*, through which there passes a rod *bb*, fixed at its upper end Fig. 11.

[1] *Edinburgh Journal of Science*, October 1824, p. 212.

[2] *Id.*, October 1825; and *Quarterly Journal*, No. xxxviii., p. 338.

Phenomena and Laws.

to a small glass receiver *abc*, and carrying at its opposite end a mass of metal P. When the jar has been electrified interiorly, it is placed in another vessel filled with ice, so that the conducting rod RS is without it. The cork *gg* and the metal P having been taken out, and the mass P heated and replaced as in the figure, the iron P will gradually heat the interior of the bottle without sensibly altering the temperature of its outer surface, which is surrounded with ice. If we then present the button S to an electroscope, there will be perceived an indication of free electricity, and consequently the heat has not increased the action of the electric fluid in the interior of the jar; for if it had done so, the electricity of the exterior surface would have been decomposed, and the rod RS would have communicated to the electroscope the repelled electricity.

But though heat exerts no action on the free fluid, this is far from being true with the natural fluid. When a metallic wire, which we may call mm', or a series of metallic molecules m, m', m'', &c., connected together by the force of aggregation, is connected by one of its ends with a heated body, such as a piece of red-hot glass, the moment that the heat enters it this extremity becomes positively electrical, while the negative electricity is driven to the adjacent molecules; but m' receiving the heat of m, m'' that of m, &c., the second molecule, which is heated at the expense of the first, takes from this last its positive electricity, and gives to it negative electricity, and so on for all the other molecules. Hence there will arise a series of decompositions and recompositions of the natural fluids while the elevation of temperature lasts.

M. Becquerel's next experiment was to place on the upper plate of Bohnenberger's gold-leaf electroscope (taking care to avoid the contact of metals) a platinum wire whose other end is coiled into a spiral. This outer end is brought to a red heat by a spirit-lamp, which is soon withdrawn, and the spiral is then touched with a band of wet paper. After having made the lower plate communicate with the common reservoir. the small band of paper is found to have carried away positive electricity, and negative electricity remains free on the surface of the metal. If we repeat the experiment in an inverse manner, that is, if we hold between the fingers the platinum wire by the end opposite to that of the spiral, and make this last communicate when it is red hot with a band of wet paper, we shall find that the band carries away positive electricity. This result, which takes place also with gold and silver, does not depend on the electricity which is disengaged during the combustion of the alcohol, since the experiment did not commence till the lamp was withdrawn. Nor can it be ascribed to the presence of water in the band of paper, nor to the alteration of the latter by the effect of heat, two causes which are capable of producing electricity, since the same result is obtained when we carry away the positive electricity of the metal by a tube of glass brought to the same temperature as the metal.

In order to make the experiment in this way, take a glass tube of a very small diameter, and whose length is little more than half an inch, and fix to one of its ends a platinum wire one fiftieth of an inch in diameter, soldering it with a lamp. A wire of the same metal, but of a very small diameter, is fixed at the other end of the glass tube, and the largest platina wire is then put in communication with one of the plates of the condenser, avoiding the contact of metals, and the free end of the other wire is held between the fingers. A red heat is then communicated to the end of the small tube to which this last wire is fixed. As its temperature is much higher than that of the other, which is larger and more distant from the focus of heat, and as the tube becomes at the same time a conductor of electricity, the natural electricity of each wire is decomposed. According to the disposition of the apparatus, we shall have the difference of the effects, which will be to the advantage of the small wire, whose end in contact with the tube possesses the highest temperature. In order to obtain this result, it is not necessary to use a heat so high as that of a red heat. By this process we avoid every foreign cause which is capable of modifying the result.

Iron and copper give similar results; but the electric effect produced by oxidation is in this case combined with that of difference of temperature. M. Becquerel has proved that the oxidation is not the sole cause of the electricity obtained with oxidable metals; and he concludes that heat exerts over the natural electric fluid of all metals a similar action, which probably varies in intensity in different metals, according to their nature. With bismuth, tin, and antimony, the effects are scarcely sensible.

The following is Becquerel's theory of the preceding phenomenon. It is an incontestable fact that all bodies contain between their molecules a neutral electric fluid; and M. Becquerel thinks that a rise of temperature establishes round two contiguous molecules an accumulation of opposite electricities, the quantity of which is proportional to this temperature, but whose recomposition is effected without there having been an apparent separation of the two electricities. It is therefore an electrical effect of motion. When the molecules are separated, each of them takes the excess of electricity relative to the portion of electricity which surrounds it.

The influence of heat on the natural electricity of metals may be shown by means of the lamp without flame, in the two following experiments given by Becquerel. Let AB, fig. 12, be a copper lamp filled with alcohol, *cc* a tube, and *dd* a cork through which there passes a glass tube EF, covered with a varnish of gum-lac. A cotton wick passes through this tube, one end of it going into the alcohol, while to the other end there is fitted a platina spiral *g*, which becomes incandescent throughout as soon as its temperature is sufficiently raised. By means of this construction the platina spiral communicates with the interior of the lamp only by means of the vapour of alcohol and the wick. If we now place this apparatus on the upper plate of an excellent electroscope, whose lower plate communicates with the ground, and touch the spiral with an ordinary platina wire, it is evident that we carry off the negative electricity which the spiral takes during the combustion of the alcohol, and also the negative electricity furnished by the end of the wire which has the lowest temperature. In this case the spiral will be found to have become positively electrical. If we touch the spiral with a band of wet paper, a contrary result will be obtained; the spiral will become negatively electrical, because the incandescent metal transmits positive electricity to the wet paper, which is no doubt stronger than the negative electricity acquired by the spiral during combustion.

Plate CCXXV., fig. 12.

Sect. III.—*On the Electricity produced by Pressure.*

Experiments of M. Haüy.

The electricity produced by pressure seems to have been first observed by Æpinus. The Abbé Haüy subsequently studied it in Iceland spar, which seems to be more susceptible of this species of excitation than any other mineral. If we take into one hand a rhomb of this mineral, holding it by two of its opposite edges, and at the same time lightly touch two of its parallel faces by two fingers of the other hand, and then bring it near to the small needle of the electroscope, it will exhibit *vitreous* electricity. If the two opposite planes, in place of being touched, are pressed between the fingers, a still greater degree of electricity will be developed.

M. Haüy has observed this property of becoming positively electrical by pressure in topaz, especially the variety which is colourless, euclase, arragonite, fluor-spar, and car-

Phenomena and Laws.

bonate of lead, all of them substances which are capable of being mechanically cleaved into smooth laminæ. The experiments are always most successful with pure and transparent specimens. Sulphate of lime and sulphate of barytes do not evolve electricity by pressure.

In all the minerals above named which furnish positive electricity by pressure, positive electricity is also produced by friction; and in those substances which develop resinous electricity by pressure, such as a properly shaped piece of elastic bitumen, resinous electricity is also produced by friction. Hence it has been inferred, that in pressing minerals friction is produced, and that the preceding phenomena are only those of excitation by friction.

Experiments of M. Libes.

M. Libes, however, has stated a fact which appears to be hostile to this explanation of the phenomena. He took a metallic disc insulated by a glass handle, and having pressed it on the surface of varnished silk, either when single or several times folded, the *disc* acquired *resinous* and the *silk vitreous* electricity, and the quantity of electricity increased with the pressure. In order to ascertain if friction was a remote cause of these effects, he set the disc lightly down upon the silk, and rubbing it backwards and forwards so as to produce the effects of friction, the *disc became vitreously and the silk resinously electrified,* a result the very opposite to that which was produced by pressure.

Experiments of M. Becquerel.

This curious subject has been recently examined with much attention and success by M. Becquerel. Having constructed an apparatus for compressing two bodies with a given quantity of pressure, and also an electrical balance of Coulomb, whose platinum torsion wire is sufficiently fine to compare very small electric forces, M. Becquerel sought to determine the phenomena which took place when two bodies were placed under the action of a given pressure and then quickly separated. He found that the excess of electricity acquired by each body was proportional to the pressure as long as it was not great enough to disorganize the body; but if the two bodies are exposed to a certain pressure, and if this pressure is reduced to one half without changing the contact, the effect of the pressure lost subsists during a time which depends on the degree of conducting power, so that if we immediately withdraw the bodies from compression, each of them will carry off an excess of the opposite electricity greater than that due to the remaining pressure. In place, however, of separating the bodies when the pressure has been diminished, let the pressure taken away be restored, and let this mode of action be several times repeated, the following results will be obtained:

Let a very thin disc of cork be pressed against a plate of Iceland spar with a weight of four kilogrammes; without changing the contact, let this pressure be reduced to one half, and after a minute let the bodies be separated. The tension or intensity of the electricity of each disc is represented by 170. When the separation took place during the whole pressure of four kilogrammes, the intensity would have been 250; and during a pressure of two kilogrammes it would have been 125, or one half. Hence it appears, that in the first case the effect produced by the pressure which was lost still subsisted in part, for it would only have been 125 for two kilogrammes, in place of 170, as given by experiment.

In place of separating the bodies when the pressure has been reduced from four to two kilogrammes, let the pressure of two kilogrammes which was removed be restored, and let us repeat several times the alternate action of simple and double pressures; it will then be found that the disc of each never possesses a greater electrical intensity than 250 relative to the strongest pressure. From these results M. Becquerel draws the following conclusions: first, that the electricity developed by pressure is proportional to the pressure; and, second, that when the molecules have been compressed, the effect of the pressure lost will subsist for some time, even though the contact has not ceased to subsist. This is not the case with conducting bodies, seeing that the two electricities disengaged instantly recombine whenever the pressure ceases.

The following are some of the numerical results obtained by M. Becquerel:

Cork pressed against	Pressures.	Intensity of Electricity.
Iceland spar	1	1·5
	2	3·4
	3	5 6
	4	6
Polished crystals of sulphate of barytes	1	1·05
	2	2·1
	3	3·1
	4	4·2
	6	6·3
Polished quartz	4	3·9
Sulphate of lime	4	1 9

When two insulated discs, one of cork and the other of caoutchouc, are pressed against each other, the cork after pressure is negatively electrical, and the caoutchouc positively electrical. When the cork is pressed against the skin of an orange, the cork is positive and the skin negative.

When cork is pressed against Iceland spar, sulphate of lime, fluor spar, sulphate of barytes, the cork is negative and the minerals positive; but when cork is pressed against kyanite, retinasphaltum, pit-coal, amber, zinc, silver, &c., the cork is positive, and the minerals or metals negative.

When insulated cork is pressed against any part of the animal body free from moisture, the cork receives an excess of negative electricity. The hair and down of animals produce nearly as much electricity by pressure as Iceland spar, but of the opposite kind. Cork pressed lightly against inspissated oil of turpentine is negatively electrified.

When two discs of the same substances, such as skin or amadou, are pressed against each other, the one becomes negative and the other positive.

The electricity thus developed by pressure is lasting. Haüy found it to continue eleven days with Iceland spar. Sulphate of barytes of Royat parts with it instantly unless well insulated; but a well insulated crystal retains it half an hour. The duration of the electricity seems to be inversely as the conducting power. Becquerel supposes the internal surface of the body to be, like the Leyden jar, charged with the opposite electricity; so that dissipation is prevented by the action of the two electricities.

In these phenomena the electricity never appears till the bodies are separated.

When the temperature of any body is raised, it has the greater tendency to acquire negative electricity by friction. In like manner, by heating Iceland spar, it may be made to give *negative* electricity by pressure against cork. If we cut a piece of well-dried cork into two pieces by a very sharp knife, and press the cut surfaces against each other, no electricity is developed; but if one of the pieces is heated slightly near the flame of a candle, and the pressure applied, each surface will, when separated, exhibit opposite electricities. The same is true of two pieces of Iceland spar.

Sect. IV.—*On the Electricity produced by Cleavage and Separation of Parts.*

Electricity by separation of parts.

It has been long known that electricity is produced during the violent disruption of a body, or by tearing it asunder, or by separating a laminated body, or by breaking a body across, or by crushing it, or even by cutting it into portions.

Phenomena and Laws.

Mr Bennet observed that when an unannealed glass tear, or Prince Rupert's drop, was put upon a book, it electrified the book negatively. Mr Wilson noticed that if a piece of wood, when dry and warm, is rent asunder, one of the separated surfaces becomes vitreously and the other resinously electrified. When a stick of sealing-wax is broken across, one of the surfaces of fracture is vitreously and the other resinously electrified.

Flash from Rupert's drops.

The electricity developed by the bursting of a Prince Rupert's or unannealed glass drop was found by Sir David Brewster to be accompanied with a flash of light. "These drops," says he, "have three different cleavages, one like the lines of a melon diverging from the apex of the drop, another concentric with the surface of the drop, and another oblique to the axis. Having laid one of these drops upon a table in a dark room, and covered it with a plate of thick glass to prevent any of the fragments from reaching the eye, the drop was burst by breaking off a part of its tail, and the whole of it appeared luminous, so that at the instant of the fracture a quantity of faint light, of the same shape and size of the drop itself, was distinctly visible. The drop which gave this singular result was made of flint glass, and was the largest that he had ever seen. Every other flint glass drop produced a distinct electrical light; but in none of them except the large one could he see the luminous shape of the drop. The same light appeared when they were burst under water. The small glass drops made of bottle-glass never exhibited any light at the moment of bursting; but it was almost always visible, in small sparks, in bottle-glass drops of a larger size." The same author observed also a bright electric light when the water-proof cloth manufactured by Charles Mackintosh, Esq., was separated by tearing it into its two component pieces, which are united by a thin film of caoutchouc. He found also that the same light was produced by tearing quickly cotton and other cloths, and by separating the films of mica. The same effects are produced by breaking barley-sugar or sugar-candy.

When the plates of mica, or the laminæ of sulphate of lime, are quickly separated, each of the two plates, when separated, carry off an excess of the opposite electricities, the one being vitreously and the other resinously electrified. If these two plates are again placed together in the position which they occupied previous to their separation, and a slight pressure used to make them adhere, M. Becquerel found that the same phenomena took place as at the instant of their first separation, that is, each plate took the same kind of electricity. This property continued only a few moments, perhaps till the molecules had taken their ordinary state of equilibrium, which is aided by increasing their temperature. The effects above described he found to be more distinct in proportion as the crystal was more heated previous to the cleavage.

Cleavage.

The electrical phenomena produced by cleavage, and by tearing asunder and crushing bodies, differ in degree only from those produced by pressure, as in every case of a separation of parts there must be an approximation of the molecules in one direction. If we press, for example, a piece of caoutchouc in one direction, or draw it out in an opposite direction till it breaks, the effect of both these mechanical actions is an approximation of the molecules in the same direction. Hence the electrical phenomena are nearly the same. The light produced by the collision of hard bodies, or by the separation of the parts of bodies, is no doubt produced by the rapid recombination of the two electricities when developed at the points of pressure.

Cleavage of topazes.

A very curious phenomenon was observed by Sir David Brewster during his numerous experiments on the cleavage of topazes, in which there were cavities containing very highly expansible fluids. His practice was to make the cleavage plane pass through a fluid cavity, and thus to open the cavity and allow its contents to be seen and examined. When this was done, the most expansible of the two fluids flowed from the cavity upon the polished and electrified face of cleavage, and continued to expand and contract itself alternately, now collecting itself into a drop, and then expanding itself into a flat disc. These motions continued till the fluid evaporated; and the effect was no doubt owing to the electricity produced by evaporation, as well as to that produced by cleavage.[1]

Wood shavings.

The experiments of Mr Wilson on the electricity of wood shavings belong, to a certain extent, to the present section. Having had occasion to work very dry wood that had lain for several hours over a very large fire, he observed the shavings adhering to the tools and to everything that they came in contact with. When the dry wood was scraped with a piece of window glass, the shavings were always vitreously electrified; but when it was chipped with a knife, the electricity of the chips was vitreous when the wood was hot and the knife not very sharp, but resinous when the wood was perfectly cold. The electricity of the knife was always opposite to that of the chips. The surface of the shaved or chipped wood was seldom electrified, but when it was, the electricity was very feeble, and of the same kind as the weakest of the other two. The wood used in these experiments was beach and cherry tree.

Sect. V.—*On the Electricity of Sifted Powders.*

Sifted powders.

As it has not been determined whether the electricity produced by the falling of sifted powders arises from friction, pressure, or separation of parts, we have thought it best to describe them in a separate section.

Bennet's experiments.

In 1786 Mr Bennet observed that when powdered chalk was blown from a pair of bellows upon the cap of his gold-leaf electrometer, *vitreous* electricity was produced when the cap was *six* inches from the pipe of the bellows, and *resinous* electricity when the distance of the pipe was *three feet*. The vitreous electricity first produced was changed to resinous by breaking the stream of air in the bellows-pipe with a bunch of wire, silk, or feathers, or by removing the pipe so as to make air issue in a wide stream.

When the plate which receives the powders at a distance of *three* inches was moistened or oiled, Mr Bennet found that the electricity was opposite to that produced when the plate was dry.

When powdered chalk fell from one plate to another placed upon the electrometer, resinous electricity was produced; and Mr Bennet obtained the same result when he used red ochre, yellow rosin, coal ashes, black lead, powdered quicklime, powdered sulphur, flowers of sulphur, sand, rust of iron, or iron filings.

When powdered chalk was placed on a metal plate upon the cap of the electrometer, and blown away with the mouth or bellows, it produced permanent vitreous electricity; and the same result is obtained if the chalk is merely blown over the plate, or if a chalk is drawn over a brush placed on the plate.

When chalk, or other powders, was sifted upon the cap of the electrometer, *resinous* electricity was produced; but when the instrument was placed in a dusty road, and the dust excited by a stick fell upon the cap, *vitreous* electricity was developed.

Experiments of Mr Singer.

The most accurate experiments on the electricity of powders were made by Mr Singer. The following results were obtained by sifting the powders on the cap of a delicate electrometer, through sieves of hair, flannel, or muslin, the sieve being cleaned after every experiment.

[1] See *Edinburgh Transactions*, 1823, vol. x., p. 27.

Phenomena and Laws.

Experiments of Mr Singer.

The following bodies produced *negative* electricity:—

The metals.	Acetate of copper.
The earths.	Sulphate of copper.
Oxides.	Sulphate of soda.
Acids.	Phosphate of soda.
Starch.	Carbonate of soda.
Sulphur.	Carbonate of ammonia.
Silex.	Carbonate of potash.
Alumine.	

The following bodies produced *positive* electricity:—

Wheat flour.	Wood charcoal.
Oatmeal.	Sulphate of potash.
Lycopodium.	Nitrate of potash.
Quassia.	Acetate of lead.
Powdered cardamum.	Oxide of tin.

Mr Singer obtained the following results by bringing an insulated copper plate repeatedly in contact with extensive surfaces of powders spread upon a dry sheet of paper, the copper plate being brought in contact with the condenser after every repetition of the touching, until a sufficient charge was communicated. Very distinct effects were produced with the alkalies by contact with a copper or silver plate, an experiment which had failed in the hands of Sir H. Davy. The pure alkali being broken into small pieces, was exposed in an open phial for a quarter of an hour to a moderate heat not sufficient to fuse the alkali. It was then reduced quickly to a powder in a dry and warm mortar, and distributed instantly over a dry sheet of card paper, which for some time continued to attract moisture from the alkali as rapidly as the alkali absorbed it from the air. The whole operation was performed as rapidly as possible. The following tables contain the substances that gave positive and negative electricity, the copper plate being always electrified oppositely to the powders.

Electricity Positive.

Lime.	Pure potash.
Barytes.	Common pearl ashes.
Strontites.	Carbonate of potash.
Magnesia.	Carbonate of soda.
Pure soda.	Tartaric acid.

Electricity Negative.

Benzoic acid.	Alumine.
Boracic acid.	Carbonate of ammonia.
Oxalic acid.	Sulphur.
Citric acid.	Rosin.
Silex.	

From the preceding experiments, which were several times repeated with uniform results, Mr Singer infers that they are unfavourable to the idea of natural electric energy; and he considers the result with sulphur and resin, viz. that the electricity is similar to that produced by their friction, as almost establishing the opinion that the contact of dissimilar bodies is in general the primary source of electrical excitation.

CHAP. III.—ON THE ELECTRICITY PRODUCED BY CHANGE OF FORM.

It has been long ago observed that electricity is developed when bodies change their form, or pass from one state into another. This important fact is exhibited when melted bodies pass from the fluid into the solid state, when fluids are converted into vapour, and when bodies are decomposed by combustion. The phenomena exhibited in these cases of change of form are very interesting, and will be described in the following sections.

SECT. I.—*On the Electricity developed during the Melting and Cooling of Resinous Bodies.*

Electricity of melted bodies.

In our history of electricity we have already given a general account of the experiments by which Mr Stephen Gray discovered a method of developing electricity by the fusion and cooling of resinous bodies. In his nineteenth experiment he formed a large cone of stone sulphur of thirty ounces avoirdupois, by melting the sulphur in a tall glass. The cone began to attract bodies two hours after it was taken out of the glass, and the glass itself exhibited a feeble attractive power. When the sulphur was lifted out of the glass on the following day, its attractive force was very strong, and that of the glass imperceptible. In making these experiments Mr Gray had occasion to place the cone of sulphur on its base between the two windows of his chamber, and to invert the glass over it. Whenever the glass was removed from the cone of sulphur, it exhibited electrical attraction as strongly as the cone, and they both preserved the property for several weeks. The glass, however, at last attracted at a less distance than the sulphur, that is, its attractive force diminished most quickly.

Experiment of Wilcke.

These interesting inquires were resumed by Mr Wilcke of Rostoch, who gave the name of *spontaneous* to the electricity developed by cooled resins. He found that the sulphur acquired a strong electricity whether the glass in which it was fused was insulated or not; but it was always stronger when the vessels were not placed on electrics, and strongest when the glass vessel had a metallic coating. The electricity of the glass was always *positive*, and the sulphur *negative.* The electricity of the sulphur did not appear till it began to cool and contract, and it was a *maximum* at its point of greatest contraction. At this time the electricity of the glass was a *minimum,* having previously reached its *maximum* at the time when the sulphur was shaken out of it. Melted *sealing-wax* becomes *negatively* electrical when poured into *glass*, and *positively* electrical when poured into sulphur. Sealing-wax poured into a vessel of baked wood showed negative, and the wood positive electricity. When sulphur was poured into wood it was negative, but it acquired no electricity whatever when poured into sulphur or rough glass.

Of Æpinus.

Æpinus pursued this subject by melting the sulphur in metallic dishes. The sulphur and the dish showed no electrical signs when they were cooled, but the moment they were separated the electricity of each was very strong, that of the dish being always negative, and that of the sulphur positive. The electricity invariably disappeared when the sulphur was replaced in its dish, and reappeared upon their separation.

If the electricity was abstracted either from the sulphur or from the dish when they were separated, they both exhibited, when re-united, the electricity which had not been taken away, and which always existed *on the surface* of the sulphur.

Electricity of melted chocolate.

Mr Sanders, a maker of chocolate, having observed that the chocolate exhibited electricity during its cooling, communicated the fact to Mr Henley, who having previously repeated the experiments of Mr Gray, resumed the subject. From several experiments made by Mr Sanders under his direction, he found that by heating the chocolate over and over again, the electrical property gradually disappeared; and that it could at any time be restored by the addition of a small quantity of olive oil.

Experiments of Van Marum.

The most elaborate series of experiments on this subject were made by MM. Van Marum and Van Troostwyck. The substances which they employed were sulphur, sealing-wax, gum-lac softened with rosin, rosin, pitch, and wax. These substances were all poured when in a fluid state on the surface of mercury, and all of them, except the sulphur, were electrical after their removal from the metallic surface. These soft solids were next melted in insulated vessels of baked clay, and also in linen and gauze insulated by silk cords; but though Volta's condenser was employed, no proof could be obtained that they had lost any portion of their natural quantity of electricity.

The electricity owing to friction.

In order to verify the suspicion that friction was the source

Phenomena and Laws.

of the electricity generated in the melting and cooling of soft solids, they poured them upon copper, tin, lead, glass, and porcelain, and they invariably found *that they acquired the same kind of electricity as if they had been rubbed by the body on which they were poured.* In confirmation of this opinion they found that the lower surface of each plate was much more strongly electrified than the upper one, and no difference of effect was perceived when the plates were even one inch and a half thick. To obtain still more complete evidence of this conclusion, they melted gum-lac and rosin, and having suspended plates of copper by silk cords, they caused the plates to come in contact with the melted gum, without producing any friction. After the gum was cooled, and the plates again raised, not a trace of electricity could be discovered.

From these results their authors infer that the electricity exhibited in this class of phenomena is not produced either by the separation of the fused substance from the electric on which it is melted, or by the fusion or subsequent cooling of the body, but that it is generated by the friction which the particles of the electric bodies undergo when they disperse themselves over the surfaces of the dishes into which they are poured. The electricity thus produced is masked or counterbalanced by the opposite electricity acquired by the dish, and therefore does not appear till the one is separated from the other.

Electricity of congelation and sublimation.

The electricity produced during the congelation of glacial sulphuric acid and other substances has probably a similar origin; and it is likely that the electrical effects which are observed when calomel fixes itself by sublimation to the upper part of a glass vessel, may belong to the same class of facts. This branch of the subject, however, has been but very imperfectly studied, and will form a fine topic of research for some young and active philosopher.

SECT. II.—*On the Electricity developed during Evaporation and the Extrication of Gases.*

Electricity of evaporation.

The development of electricity during the transition of bodies from the solid or fluid state into the state of vapours or gases, was first investigated by MM. Lavoisier and Laplace, with the assistance of M. Volta. Two kinds of apparatus were used in these experiments. In both of them the bodies to be vaporized were insulated by varnished supports of glass; and in those cases where the electricity was quickly disengaged, a common electroscope communicating with the body was used to indicate it, whereas, when the effect was likely to take place place continuously, Volta's condenser was employed.

Experiments of Lavoisier, Laplace, and Volta.

Electricity of chemical action;

When hydrogen gas was rapidly disengaged from iron filings by the action of sulphuric acid, the condenser of Volta afforded a strong spark, and the electricity was negative.

When carbonic acid gas was evolved from powdered chalk, no sensible spark was educed, but the electricity generated was negative.

When nitrous acid diluted with two parts of water was poured upon iron filings placed in six separate vessels, so as to generate nitrous gas, a distinct negative electricity was obtained without a spark.

of combustion;

During the combustion of charcoal in three insulated chafing dishes strong negative electricity was generated; and a spark could easily have been obtained, by increasing the quantity of charcoal.

of evaporation.

Having arranged three insulated furnaces of hammered iron, and made them communicate with the electroscope, water was thrown upon them when heated. In the first experiment the electricity generated was *negative*, and in the other two *positive;* a discrepancy which they ascribed to the cooling which accompanied the evaporation, the positive electricity produced by cooling being supposed to counterbalance the negative effect occasioned by evaporation.

Phenomena and Laws.

Bennet's experiments.

Mr Bennet, before whom Volta had repeated his experiments in England, published in the *Phil. Trans.* for 1787 the following interesting facts on the same subject. Having placed a metallic cup with a red-hot coal in it upon the cap of his gold-leaf electrometer, he threw a spoonful of water into the cup. The cup was electrified *negatively*, while the ascending column of vapour exhibited *positive* electricity. When water is poured through an insulated cullender, containing hot coals, the *descending* drops of water are *negatively*, and the *ascending* vapour *positively* electrified; and Mr Bennet regards this as a good illustration of the electricities of fogs and rain. A more simple and certain method of making these experiments consists, according to Mr Bennet, in heating the small end of a long tobacco pipe, and pouring water into the head. The water, being allowed to run through the heated end, is suddenly expanded into steam, and, when projected upon the cap of the electrometer, exhibits signs of electricity. If the pipe, when fixed in a cleft stick, is fixed on one electrometer, while the steam is received upon the cap of another, the two opposite electricities will be simultaneously exhibited. The vapour of alcohol and ether exhibits the same phenomena as that of water, but sulphuric acid and oil generate only smoke, and exhibit no electrical indications.

Experiments of Saussure.

M. Saussure devoted much attention to this interesting branch of electricity. He confirmed the general results obtained by Volta, Lavoisier, and Laplace, and proved that negative electricity was constantly produced by the evaporation of water. He then determined the degree and kind of electricity produced by evaporation when it was carried on in vessels of different metals, and kept at different temperatures. The apparatus which he employed consisted of a well-baked vessel of clay, four inches in diameter and fifteen lines thick, which was insulated upon a clean and dry goblet of glass. Upon this clay vessel he placed a crucible, or any other dish powerfully heated; and this crucible was made to communicate with the electrometer by means of a wire. Fifty-four grains of distilled water were then thrown upon the crucible, and, by means of a time-piece and an electrometer, he observed the duration of the evaporation, and the intensity and character of the electricity.

In his first series of experiments the crucible was of iron; the number of projections of the water varied from 1 to 21, the time of the projection from 0″ to 17′, the duration of the evaporation from $2\frac{1}{2}''$ to 118″, and the degree of electricity from 1 to 18 tenths of a line. In *ten* of these experiments the electricity was *positive*, and in *six negative.* In four of the negative experiments the strongest electricity was 7, 13, 17, and 18 tenths of a line, and in four of the positive experiments the strongest was 3, 3, 5, and 8 tenths; thus showing, as might have been thought, that the weak positive electricity was produced by some secondary cause.

But in repeating the same series of experiments with the same iron crucible, he found very different results. The projections of water varied from 1 to 23, their time from 0′ to 14′ 10″, and the duration of the evaporation from $2\frac{1}{2}''$ to 120″. The electricity was now *always* positive, and its intensity varied from 0 to 30 tenths of a line.

When the experiment was repeated with a *copper crucible* $3\frac{1}{4}$ inches wide at top, 2 inches wide at bottom, 3 inches high, and weighing 57 ounces, the electricity was always *positive*, and its intensity varied from 0 to 33 tenths of a line, the maximum effect taking place when the duration of evaporation was 165″, a mean between the shortest and longest times. In another experiment with the same *copper* crucible, made under the very same circumstances, the electricity was negative at the end of the first projection, but afterwards became positive, and continued so till the experiment was complete.

In the next experiment the crucible was of *pure silver*, $2\frac{3}{4}$ inches wide at top, $1\frac{1}{2}$ at bottom, $12\frac{1}{2}$ inches high, $1\frac{1}{2}$

Phenomena and Laws.

line thick, and weighing 16 ounces. At the first trial, when the evaporation was very slow, the electricity, which was always very feeble, was *thrice negative*, and thrice 0. In a second trial it was also negative at first, but it became *positive* afterwards, and then vanished. In a third trial the electricity was stronger and negative. The balls of the electrometer now diverged $3\frac{1}{2}$ lines. It then became *positive*, when the balls diverged $\frac{7}{10}$ths of a line; and at the third projection, when it was still positive, the separation of the balls was so great as *six* lines.

Saussure's next experiment was made with a cup of white *porcelain*, surrounded with sand in a clay crucible. The electricity was *negative*, and the evaporation remarkably rapid. Its intensity varied from 0 to 8 lines. The same results were obtained with different porcelain crucibles.

When *alcohol* and *ether* were substituted for water, and the silver crucible used, the electricity was *negative*. With the former the greatest intensity was 1 line, and with the latter 4·2 lines.

From these experiments Saussure infers, with great hesitation, that the electricity is positive with those bodies which are capable of decomposing water, or of being themselves decomposed by their contact with water; and that it is negative with those which are not decomposed. He ascribed the result with silver to its being adulterated with copper or other oxidable metals. The negative electricity of burning charcoal he supposes to arise from the readiness with which it loses its heat in contact with water.

Saussure was unable to procure electricity either from combustion or by suddenly exploding heaps of gunpowder; and all his attempts failed to develop electricity, *without ebullition*, by evaporation, from large surfaces of wet linen or white iron.

Experiments of Cavallo.

M. Cavallo followed Saussure in this inquiry, though he does not seem to have been acquainted with the labours of the Swiss philosopher. He found that evaporation from iron produced negative electricity when the iron was free from rust, but positive when it was very rusty. He found also that white and clear flint glass produced *positive*, while bottle glass evolved *negative* electricity. From these various researches it is not easy to deduce anything like a general principle. The subject indeed requires to be resumed, and great attention paid to the chemical changes which take place during the progress of the experiments.

SECT. III.—*On the Electricity developed in Flame and Combustion.*

Electricity of flame.

We have already seen in the preceding section, that MM. Lavoisier and Laplace obtained distinct indications of electricity by the combustion of charcoal, and Volta informs us that he never failed to obtain it. Saussure, on the contrary, as has been mentioned, never could develop electricity either by combustion or the explosion of gunpowder; and Sir Humphry Davy equally failed to procure it by the combustion of iron or of charcoal in air or in pure oxygen.

Experiments of Erman.

The electrical relations of flame have been subsequently examined by M. Erman of Berlin and Professor Brande. M. Erman concluded, from some experiments, that the insulated flames of *wax, oil, alcohol*, and *hydrogen gas* conduct *only positive* electricity, while the flame of *phosphorus* conducts only *negative* electricity. It was noticed by Mr Cuthbertson that when the flame of a common candle was placed halfway between two equal balls, the one positively and the other negatively electrified, the flame was attracted to the *negative* ball, which consequently became very warm, while the positive ball continued comparatively cold.

In pursuing this idea, Mr Brande placed the flames of various bodies between two insulated brass balls, one of which was insulated positively and the other negatively, and obtained the following results.

Experiments of Brande.

Flames, &c., attracted to the Negative Ball.

Olefiant gas.
Sulphuretted hydrogen, slightly.
Arseniated hydrogen.
Flame of hydrogen, weakly.
Sulphuret of carbon.
Potassium in combustion, and its fumes.
Flame of gum benzoin.
Smoke of benzoin.
Charcoal emitted by camphor in combustion.

Resinous bodies in combustion exhibit the same phenomena as charcoal.

Flames attracted to the Positive Ball.

Sulphurous acid vapour.
A *small* flame of phosphuretted hydrogen, slightly.[1]
Fumes of white arsenic, slightly.
Large flame of carbonic oxide.
Vapour of burnt sulphur.[2]
Flame of phosphorus.
Vapour of phosphorus.
Stream of muriatic acid.
Stream of nitrous gas.
Vapour of benzoic acid.

In order to explain these phenomena, Mr Brande supposes, that since some bodies are naturally negative and others positive, the positive ones will be attracted by the negative ball, and the negative ones by the positive ball.

This conjecture was not confirmed by future observation, and did not lead philosophers to any certain conclusions. The subject, however, was resumed by M. Pouillet, who arrived at a general result, which explains in a satisfactory manner the errors and contradictions of preceding observers.

Experiments of M. Pouillet.

The first point which occupied his attention was the combustion of charcoal; and in his earliest experiments he found with surprise that he could sometimes obtain from it positive and at other times negative electricity, while at other times he could not obtain the slightest electrical indications. In explaining these discrepancies, he supposed that one of the electricities was taken by the charcoal, and the other by the oxygen or carbonic acid; and in order to determine the truth of this supposition he made the following arrangement.

Combustion of charcoal.

Having taken a cylinder of charcoal, he placed it vertically six or eight centimeters below a plate of brass which rests upon one of the discs of the condenser. The charcoal having a communication with the ground, was lighted at its upper end without the fire reaching the lateral surface, and there arose a column of carbonic acid, which struck the plate of brass, and in a few seconds charged the condenser. The electricity which the condenser received from the carbonic acid was *always positive*, whereas Lavoisier, Laplace, and Volta made the electricity *negative*. When the charcoal was held nearly horizontally, so that the carbonic acid which was generated could rise only by ascending along the base of the charcoal, which was now vertical, *no sensible effect was obtained;* and when the lateral as well as the upper surface of the charcoal, placed vertically, was lighted, an uncertain result was obtained.

In order to determine the electricity of the charcoal itself, M. Pouillet placed the base of the cylinder upon the disc of the condenser; and after lighting the upper end of it, and keeping up the fire by a gentle blast of air, the condenser was charged, and showed that the electricity taken by the charcoal was negative. When the charcoal burned on all its surface, or when it touched the condenser only in a few points, no electrical effects were observed. In the

[1] When the flame was *large* it was equally attracted by both balls.
[2] The direction of the flame could not be determined.

Phenomena and Laws.

last of these cases a small quantity of electricity only can pass by a small number of points, and in the first case the positive electricity of the ascending carbonic acid was recombined with the negative electricity. In order to produce intense and rapid electrical effects, several cylinders of charcoal of the same height should be placed on their ends, and near each other, upon a sufficiently large plate of brass; and when all the cylinders are made to burn at their upper ends, and their united columns of carbonic acid received by another brass plate communicating with the condenser, and raised a few inches or even a foot above it, a strong charge of *positive* electricity will in a few seconds be communicated to the brass plate. When the electricity of the charcoal is required, we have only to unite the condenser to the brass plate upon which the burning cylinders are placed, and in a few seconds the condenser will be abundantly charged with *negative* electricity.

Experiments of Pouillet.

When the combustion is maintained by a current of oxygen, the electricity is not only much more intense, but is much more quickly developed; and the gold leaves of the condenser separate to their maximum divergency in an instant. The first point, however, to be attended to in every form of the experiment, is to burn only the upper horizontal surface, so that the carbonic acid forms and ascends in a moment, and without touching any other body till it deposits its electricity on the brass plate. So essential is this condition, that if we burn even a deep cavity on the circumference of a vertical cylinder of charcoal, and do this even with a jet of oxygen, the electrical indications are sometimes positive and sometimes negative, just as the electricity of the gas or the charcoal predominates.

M. Pouillet next entered upon the more arduous investigation of determining whether or not electricity is produced by change of condition or chemical affinity. Volta had supposed that carbon, in becoming gaseous, absorbed the positive, and left to the remaining solid parts the *negative* electricity which we find in them. M. Pouillet, on the contrary, supposed that if electricity is disengaged from two elements which combine, positive electricity would be given out by the one and negative by the other; and that when these elements separate, each of them required to take up the fluid which they had lost.

Combustion of hydrogen.

By forming combinations unaccompanied by changes of condition, M. Pouillet resolved this question. He first tried that of oxygen and hydrogen. The flame of hydrogen, like charcoal, gave electricity, sometimes strong and sometimes feeble, sometimes *positive* and sometimes negative; and it was some time before he discovered the cause of these discrepancies. That the gases are not very good conductors of electricity, he found by the following very curious experiment. Having set a very small spirit-lamp upon a common electroscope, and about five or six feet above it a feebly charged body, such as a stick of electrified rosin or a plate of glass, he observed that the gold leaves diverged greatly, though the same charged body could produce no divergence if held even so near as an inch to the electroscope without flame. This apparatus enabled our author to discover the smallest trace of electricity. If we turn the plate of an electrifying machine, the air of the room is electrified; and the flame which ascends in that air is charged at the moment with electricity of the same name. A pile in action electrifies the air in the same manner, as the flame of the electroscope proves. A charcoal fire, or even a lighted candle, develops carbonic acid electrified positively, which is shown also by the electroscope. The atmospheric air, in short, is always electrified: and if it enters a room by any opening, it will preserve itself in an electrified state so long as to affect the results of experiments on small quantities of electricity.

These causes of error being excluded, M. Pouillet repeated his experiments on the combustion of hydrogen. The gas was emitted from a glass tube, and the flame, which was vertical, was about three inches long and four or five lines broad. The brass plate was now set aside, and the electricity conducted to the condenser by a platina wire, whose end is coiled into a spiral. The spire is vertical, and the circumvolutions are sometimes so large as to surround the flame without touching it, and sometimes so small as to be completely enveloped in the interior of the flame. When we approach this flame from the interior outline of the spire, and keep it ten millimeters distant, we obtain indications of positive electricity. As the distance of the flame diminishes, the electricity becomes more and more intense; but when the flame touches the spire, the electricity becomes weak, and its nature uncertain. The same thing is observed when the flame passes to the interior of the spire, and in the direction of its own axis. Hence there exists round the apparent flame of the hydrogen a sort of atmosphere, more than ten millimeters in thickness, charged with positive electricity. Positive electricity being thus developed in the combustion of hydrogen, Pouillet tried to discover the negative electricity which must have been set free. He placed a small spiral in the centre of the flame, and when it was enveloped on all sides, negative electricity was collected by the condenser. If we plunge the spire half way into the bright part of the flame, no electricity is manifested. Hence it follows that the inside and outside of the flame are in opposite electrical states, the former being negative and the latter positive, and that there is an intermediate layer of the flame where the electricity disappears. On these facts M. Pouillet thus reasons. In the thickness of the exterior atmosphere of the flame, when the positive electricity appears, the combination of oxygen and hydrogen is not effected, for the hydrogen cannot arrive there. The electricity is therefore communicated, and it must come from the oxygen which predominates on the outside, and which envelopes in some measure all the jet of hydrogen. This combined oxygen must therefore disengage positive electricity, which communicates itself to the neighbouring strata of air sufficiently heated to conduct it. In like manner the hydrogen predominates in the interior of the flame, and the negative electricity must be disengaged from the hydrogen which burns, and which it communicates to the excess of uncombined hydrogen. If this view is correct, it is probable that, at a certain distance above the flame, the two opposite electricities ought no longer to appear, as they must have combined; and this is proved to be the case by the fruitless attempt to collect electricity at a distance sufficiently great above the vertical flame. At the distance, however, of a few inches, other phenomena appear. The two electrical fluids appear there in the same quantity, but they are not recombined; for if we present a soldered plate of zinc and copper, the zinc will attract the positive and the copper the negative electricity.

Electricity of flame.

When the hydrogen issues from a metallic in place of a glass tube, and a communication is made with the condenser and not with the ground, the metal tube, which touches the hydrogen without touching the flame, always takes the negative electricity; and, on the contrary, if the tube communicates only with the ground, it loses in this manner the negative electricity which it had before taken to the condenser, and the product of the combustion preserves an excess of positive electricity.

In pursuing this inquiry in a similar manner, M. Pouillet found that the flames of alcohol, ether, wax, the oils, fatty substances, and several vegetable bodies, present exactly the same phenomenon as the flame of hydrogen. He observed, however, that the particles of charcoal which float in all these flames, and which, according to Sir H. Davy, give them the lustre with which they burn, render them also more fitted to manifest negative electricity. From these results M. Pouillet has deduced the general conclu-

Phenomena and Laws.

sion, *that in combustion the molecules of oxygen which combine disengage positive electricity, which may be communicated to the neighbouring molecules not yet combined; and that the combustible body, on the contrary, disengages negative electricity, which can, in like manner, be communicated to all the neighbouring combustible parts.*

Experiments of M. Becquerel.

The experiments of M. Pouillet were repeated by M. Becquerel in 1827, on the flames of hydrogen gas or alcohol; but he commenced them with some reserve, for, as they were made by means of platina wires plunged in the flame, he supposed that the phenomena were not only owing to the electricity disengaged during combustion, but also to some property which the metals acquired at a certain temperature. The following is the general fact, without entering into any of the details of his experiments: A platinum wire communicates by one end, through the intermedium of a band of wet paper, with one of the plates of a condenser, the other end being plunged in one of the envelopes of a flame produced by the combustion of alcohol, contained in a vessel of copper, which the observer holds in his hand. The end of the wire may even be placed without the flame, provided it is so near it as to become red hot. The wire soon takes a considerable excess of negative electricity, which ought not to be ascribed entirely to that which the alcohol carries off during combustion. In order to prove this, let us resume the last experiment but one. As soon as the end of the platinum wire attains a red heat, let us withdraw the lamp, and touch this end of the wire with a band of wet paper, or rather with the end of a tube of hot glass; the effect is the same as when the wire touched the flame, or was at a small distance from it. It is very probable that the disengagement of the electricity is due, in this last case, in part to the difference of temperature between the two ends of the wire, and that the flame has carried off the positive electricity of the wire, or the band of wet paper, as the hot glass tube had done. This opinion is confirmed by the circumstance that the effect is the same whether we bring the wire to a red heat in the interior or in the exterior of the flame, neither of which possesses the same kind of electricity. Notwithstanding this result, M. Becquerel still admits, that during the combustion of alcohol and hydrogen, the exterior envelope of the flame is charged with positive electricity.

M. Becquerel has endeavoured to explain the curious fact discovered by M. Erman, and already referred to. Having placed upon an electroscope a lamp without flame, whose platinum wire was kept at a red heat by the burning vapour of the alcohol, he held above the spiral the negative pole of a dry pile, and the two gold leaves instantly diverged. He next held the positive pole above the spiral, but there was now no divergence of the leaves. Hence the platinum wire afforded a passage only to the negative electricity. The contrary effect took place when the electricity passed from an incandescent wire to another which was not so; and hence M. Erman found that the incandescent wire was reciprocally a conductor and insulator of each fluid.

In order to show that this conclusion is incorrect, M. Becquerel presented successively to a red-hot platinum wire the two poles of a dry pile, and it conducted equally well both kinds of electricity. Besides, as he remarks, it appears, from our knowledge of the electrical effects produced in gaseous combustion, and by increase of temperature, that part of the air which surrounds the red-hot wire of the lamp without flame ought to be in a positive state of electricity, and the wire which is in the middle of the alcoholic vapour in a negative state. Moreover, it is evident, from what has been already stated, that the part of the wire which is red hot ought easily to yield positive electricity to contiguous bodies. This being admitted, when we present to this wire the negative pole of a dry pile, there are two reasons why the negative electricity should neutralize both the positive electricity of the surrounding air, and that of the red-hot wire which tends to escape from it. The negative electricity of the wire then becoming free, manifests its action upon the electroscope. In repeating the experiment in an inverse manner, that is, by causing each of the two electricities to escape successively by the red-hot wire, as this last tends to be negative, it neutralizes the positive electricity which arises, and sets free that of the surrounding air and of the red-hot end of the wire. It is not therefore necessary to have recourse to a reciprocity of insulating and conducting action in the red-hot wire in order to explain the phenomenon, for the fact admits of an easy explanation on the properties above explained.

Sect. IV.—*On the Electricity of the Solar Rays.*

Electricity of the solar rays.

Our readers are no doubt aware that Dr Morrichini and others succeeded in magnetizing needles by the action of the blue rays in the solar spectrum. Other philosophers have failed, even in good climates, in obtaining decided indications of magnetism, so that accurate researches are still wanting to remove this opprobrium from our experimental physics. The very same observations are applicable to the development of electricity by the influence of solar light; but still it is necessary, in a work like this, that we should give some account of the experiments from which this electrical action has been inferred.

Experiments of Barlocci;

In a memoir on the influence of solar light in the production of electric and magnetic phenomena, Professor Saverio Barlocci of Rome relates the following experiments: Having formed the prismatic spectrum by the solar rays, he caused the red rays and the violet rays to fall upon two discs of blackened copper, each of which was attached to a copper wire. Two copper nuts sliding upon a vertical glass rod, and to which the two wires were fixed, allowed the discs to be brought near each other or separated at pleasure. A prepared frog was then suspended by the body to the upper wire, and the legs were placed upon the lower one. The red rays being made to fall on one disc, and the violet on the other, the extreme parts of the two wires were brought into contact, and distinct signs of contraction were observed in the frog.

of Matteucci.

M. Matteucci has more recently investigated the same subject. Having exposed to the sun a delicate condensing electrometer of gold leaf, he soon perceived the leaves diverge and open themselves on that side of the glass which was directly exposed to the solar action, as if they had been attracted by it. Hence he was led to suspect that glass thus exposed was electrified; and in order to ascertain this, he placed some plates of it in the sun, and having in a few minutes touched them in different places with the ball electrometer, a perceptible divergence took place. This divergence was much more apparent when he touched the plates even lightly with a flat surface, as the effects of the friction did not afford a doubtful result.

Having inferred from these results that the solar rays had the power of developing electricity in glass, M. Matteucci endeavoured to ascertain whether this was owing to the existence of electricity in the rays themselves, or to the increased temperature of the glass. He therefore heated a plate of glass repeatedly, and having tried it with the electrometer, he never could discover in it any signs of electrical action. M. Matteucci likewise observed that the glass plate exposed to the rays of the sun never became electric if placed beneath another glass plate, or if the face of the sun was obscured by a cloud.

Experiments of Dr Faraday.

Dr Faraday likewise made experiments on the solar spectrum, in the same manner as M. Barlocci, with the exception that he used a very delicate galvanometer in place of a frog; but, to use his own words, "no electricity could be obtained by means of an English sun."

Phenomena and Laws.

M. Delarive has still more recently (*Bibl. Univers.* July 1833, p. 326) stated that, after taking every precaution to avoid the action of extraneous causes, he could not discover in the solar rays the slightest trace of electricity.

Sect. V.—*On the Electricity produced by Vegetables.*

Electricity of vegetation.

Mr Read seems to be the only author who, previous to the researches of M. Pouillet, had made any distinct statement respecting the electricity of vegetable bodies. He had concluded, from several experiments, that vegetable putrefaction is always electrified negatively, while the surrounding atmosphere is electrified positively. It is to M. Pouillet, however, that we owe all our knowledge on this subject, and in the present section we shall communicate to our readers a general abstract of his researches.

Researches of M. Pouillet.

That the various parts of plants act upon atmospheric air is well known. At the expense of the oxygen they sometimes form a large quantity of carbonic acid gas, which disengages itself insensibly; and sometimes they exhale pure oxygen, proceeding from some combination which goes on in the interior of the plant.

As carbonic acid gas is electrified vitreously at the moment of its formation, from charcoal in combustion, M. Pouillet conceived that a considerable quantity of electricity ought to be produced during the exhalation of this acid from growing plants. This idea was soon confirmed by experiment, and M. Pouillet was led to the important conclusion that vegetation is an abundant source of electricity, and is therefore a powerful cause in the generation of the electricity of the atmosphere.

He took twelve capsules of glass, about nine inches in diameter, and coated them externally, but only to a distance of one or two inches towards the edge, with a film of gum-lac varnish. They were then arranged in two rows at the side of each other, either on a table of very dry wood, or on a table which was itself varnished with gum-lac. When they were filled with vegetable mould, they were made to communicate with each other by metallic wires, which went from the interior of the one to the interior of the other, passing over the edges of the capsules. In this manner all the insides of the twelve capsules, and the mould which they held, formed only one conducting body. If electricity is communicated to such a system, it will be distributed over the twelve capsules, and will remain there, as it cannot pass into the ground, nor even into the exterior surfaces of the capsules, on account of the film of gum-lac round their edges. The upper plate of a condenser is now put in communication with one of the capsules by means of a brass wire, and its lower plate with the ground by the same means; and these communications are so made that they may be kept up even for several days. The grain of which we wish to study the effects is then sown in the earth in the capsules, and from this moment the laboratory must be closely shut, and neither fire nor light, nor any electrical body, admitted.

This experiment was made during the dry north and east winds of the month of March. During the first two days the surface of the mould was dried up, and the grains swelled; the germ projected about a line out of its envelope, without, however, appearing above the thin stratum of earth which covered the grain; and the condenser, after several trials, gave no signs of electricity. On the third day the germs had come out of the mould, and began to raise their points towards the window, which had no shutters. Upon now trying the condenser, M. Pouillet saw a divergence in the gold leaves, and he found the electricity to be negative in the capsules, and positive in the gases which were disengaged. Hence M. Pouillet infers that the rapid action which the rising germ exercises on the oxygen of the air disengages electricity.

The apparatus was then put into its usual state, and after the lapse of some hours the action of the germ again charged it with electricity. Upon visiting the apparatus next morning, M. Pouillet found that it gave a very strong electric charge, and the electricity was of the same kind as before. During the next eight days the vegetation continued active, and at all times of observation, both during the day and night, the condenser exhibited more or less electricity, according to the time that had elapsed. After twelve hours the divergence of the gold leaves was more than an inch, and the electricity of the earth in the capsules was always *negative*. Damp weather followed, and it was then impossible to collect the least quantity of electricity.

M. Pouillet's next experiment was to make two vegetations of corn, two of cresses, one of gillyflower, and one of lucerne; but he was obliged to maintain in his laboratory an artificial dryness, by spreading in a very large apartment several bushels of quicklime broken into very small fragments, and he also distributed in porcelain saucers several kilogrammes of muriate of lime, and placed them near the capsules. The condenser now exhibited a more intense electricity than before, and in each operation the development of the vegetable action, and that of the accompanying electrical phenomena, were observed during ten or twelve days. So rapid was the development of electricity, that after the first three or four days of vegetation, if the condenser was put into the natural state after one observation, and it was then replaced for experiment only during *one second*, it was found to be charged with electricity. "But," as M. Pouillet observes, "it is evident that, during one second, the weight of oxygen which combines and disengages during a languid vegetation, of only three or four square feet, is a weight so feeble, and a fraction of a milligramme so imperceptible, that the electricity which it disengages is not sensible to the condenser. One is apt to fear, after this, that the electricity has another source, and that it can only be developed by some foreign cause; but upon reflection we see that the earth of the capsules is so dry that it becomes an imperfect conductor, that the electricity is retained, and that it is it which charges the condenser. To be certain of this, it is sufficient to place successively in contact with the condenser, one, two, three, or a greater number of capsules, and we shall see the charge increase in proportion as the number increases; in short, it is sufficient to place them in communication with the ground for a long time, when they will no longer give a charge to the condenser, and it will be many hours after that before they communicate a sensible electricity. It is without doubt this imperfect conductibility of the dried earth which has rendered it impossible for me to observe until now any electrical charges during the periods of day or night, although I took every precaution to observe it, presuming that if the disengagement of carbonic acid produce resinous electricity in the ground, the disengagement of oxygen ought, on the contrary, to produce vitreous electricity.

"It is perhaps the same cause which has given birth to another phenomenon, which I have not yet studied sufficiently to give an exact account of it. It happened twice that the electric signs had ceased during two or three days, and that they were then presented in opposite directions, that is to say, the capsules had exhibited vitreous electricity, and had continued to exhibit it, with a very weak intensity, during the rest of the vegetation."

Sect. V.—*On the Electricity of Living Animals.*

Electricity of living animals.

When we consider the structure of organized bodies endued with life and motion, we should naturally expect, from the phenomena described in the preceding section, that electricity would be developed in the chemical pro-

Phenomena and Laws.

cesses and changes which are incessantly taking place. During the processes of digestion and assimilation, for example, in which both solid and fluid bodies are changing their form, and in the process of respiration, in which the atmospheric air is decomposed, electricity cannot fail to be developed in greater or less intensity.

Another source of electricity in animal bodies is no doubt the friction between the clothing and the skin; and the electricity thus generated will be more or less intense, according to the state of the atmosphere, the nature of the clothes, and the constitution and habits of the individual.

But, independent of the electrical phenomena which arise from these causes, we find in certain fishes a regular system of electrical organs, by which they either defend themselves from the attacks of their enemies, or seize the prey which nature has provided for their use. The curious phenomena which have been observed relative to these subjects will be described under separate heads.

ART. I. *On the Electricity of the Human Body.*

Electricity of the human body.

Long before electricity had become a science, electrical phenomena had been distinctly observed. Cardan relates that sparks were emitted from the hair of a Carmelite monk whenever it was stroked backwards; and Faber mentions a young woman from whose hair sparks of fire always fell when it was combed. Cassandra Buri, a Veronese lady, often terrified her maid-servants by brilliant sparks, and a crackling noise, which were emitted when her body was rubbed, or even touched slightly, by a linen cloth. Antonio Ciampi, a bookseller at Pisa, emitted sparks from his back and arms with a crackling noise, whenever he pulled off a narrow shirt and a piece of cloth which he wore upon his breast.

Gesner relates that in Germany, where heated stoves prevailed, it was exceedingly common to observe crackling flames issue from the shirts of persons who had been previously warming themselves at a stove.

The experiments of Mr Seymour on the electricity of silk stockings that had been worn, which we have already detailed, correspond with the preceding facts; and there are few individuals who have not observed similar electrical phenomena in changing different parts of their dress.

Experiments of Saussure;

That the electrical effects exhibited in the human body are, generally speaking, produced by the friction of the clothes against the skin, has been proved by the experiments of Saussure, Landriani, the Abbé Bertholon, and M. Volta. M. Saussure examined the electricity of his own body by means of Volta's electrometer and a condenser, and he never could discover any electricity in it when he was perfectly naked, when his clothes were cold, or when he was in a state of perspiration. In other states of his body and dress the electricity which did manifest itself was sometimes positive and at other times negative, without any apparent cause for these variations. When he bent his body forwards and raised himself suddenly, the balls of the electrometer diverged to a considerable distance, and then collapsed; but if he drew away his hand when the balls were thus divergent, they continued in this state of divergency, and exhibited positive electricity. Saussure observed also that the motion produced by respiration is of itself sufficient to produce a small quantity of electricity; for when he remained on the insulating stool in a state of the most perfect repose that a living being could observe, distinct indications of electricity were manifested when he laid his hand for some time on one of Volta's condensers.

of Hemmer.

The most complete series of experiments on the electricity of the human body were made by M. J. J. Hemmer of Manheim. He insulated himself upon a board supported by glass feet, and then touched for about half a minute a condenser The condenser was then applied to Saussure's improved electrometer, and, by means of a glass tube excited by woollen cloth, he examined the nature of the electricity. The following are the results of experiments which he made upon himself on the 21st of February 1786, and which he has repeated upon persons in every state of body and mind, and under every variety of dress and temperature.

1. The electricity of the human body is common to all men. It was found in thirty persons of all ages and sexes; but it varied in strength in different individuals, and was positive in some and negative in others.

2. The intensity and character of the electricity often varies in the same person. In 2422 experiments M. Hemmer found it 1252 times positive, 771 times negative, and 399 times imperceptible. Out of 94 experiments made upon his maid-servant, it was 17 times positive, 33 times negative, and 44 times imperceptible.

3. The electricity of the body is naturally positive; for when it is subject to no violent exertion this is always its character. Out of 356 experiments made upon himself when sitting at rest, and when the natural heat of his body was not disturbed, his electricity was 322 times positive, 14 times negative, and 10 times imperceptible.

4. The natural positive electricity of the body is changed into negative by cold, or is greatly diminished. Out of 62 experiments made upon himself when he came from a temperature of 32° of Fahrenheit, his electricity was 38 times negative, 15 times positive, and 7 times imperceptible.

5. The natural positive electricity of the body is changed into negative by lassitude. Out of 16 times that he walked backwards and forwards in his apartment, or was otherwise employed, he found the electricity only *once* weakly positive, 10 times negative, and 5 times imperceptible. In 32 experiments made when he was standing at rest, the electricity was 2 times weakly positive and 30 times imperceptible.

6. The natural positive electricity of the body is changed into negative by sudden, speedy, and violent motion.

It is obvious from these experiments, that the human body possesses no electrical organs over which the will exercises any control, and that its electricity depends on the chemical and physical changes which are taking place either in its interior or upon its surface.

It has been supposed that the remarkable phenomena of spontaneous combustion in the human body are somehow or other connected with its electrical state; but we possess no accurate data by which the truth of this opinion can be tried.

Researches of M. Matteucci.

Some very interesting discoveries have been recently made respecting the electricity of animals. It has been proved by M. Matteucci and M. Dubois Remond, that there are electrical currents in the frog and in all other animals, whether cold or warm blooded. According to Matteucci, the current is more feeble in proportion to the rank which the animal occupies in the scale of animals. We have witnessed the fine experiments which he performed at York in 1844, by severing the lower halves of the thighs of a certain number of living frogs, and inserting the knee of the one into the central muscles of the second, and so on. A voltaic pile was thus formed of six or eight elements, which was capable of deflecting the needle of a galvanometer, or producing convulsions in an electroscopic frog. The direction of the voltaic current was from the interior to the exterior of the muscle. M. Matteucci also showed that there was a specific voltaic current in the frog, which is directed from the feet to the head, and is detected only in that animal.

Experiments of M. Dubois Remond.

The existence of electrical currents in the human body has been proved by M. Dubois Remond by means of an extremely sensitive galvanoscope. This instrument consisted of a coil of wire 16,752 feet or $3\frac{1}{3}$ miles in length, which made 24,160 turns on the frame upon which it was

Phenomena and Laws.

wound. Its diameter was only 0·0055 of an inch. Two plates of homogeneous platina, fixed one to each end of the galvanoscope, were immersed in two vessels containing salt water. When the two corresponding fingers of each hand are plunged into these vessels, the needle of the galvanoscope deviates a little from its place; but as it does not follow any law, M. Dubois Remond ascribes it to something heterogeneous in the skin of the finger, for when there is an abrasion of the skin or a slight wound in one of the fingers, the deviation is greater than usual. When the needle has returned to its place of rest at zero, the operator, dipping his finger into the vessel, forcibly stiffens or contracts all the muscles of one of his arms, and immediately the needle begins to move through a space of 30°, indicating an *inverse* current of electricity, or one which moves from the hand to the shoulder. The greatest effect is generally produced by the strongest persons, but sometimes no effect is produced by particular individuals.

This beautiful instrument has been improved and rendered more sensitive by Mr Rutter of Brighton, who has described it in his work on *Human Electricity*. Upon

Fig. 6.

a circular stand is fixed a pillar, on the top of which is a moveable bracket with a collar and adjusting screws. An oval-shaped compact coil of insulated copper wire is suspended from the bracket by a fibre of raw silk. The ends of this wire are soldered to small binding screws at each extremity of the coil, by which contact is made with cups containing mercury. The coil or helix moves with scarcely any friction, as its terminals consist of fine silver wire, which dips into mercury. One of M. Logeman of Haerlem's horse-shoe magnets, constructed by the process of M. Elias of Haerlem, is supported horizontally with its poles as near as possible to the sides of the helix without touching them. Wires proceed from the cups of mercury and beneath the stand, and terminate in plates of platina. A brass index with an engraved dial plate is fixed on a plate at the top of the helix. On a separate bench or table are placed two basins containing about 3 quarts of pure spring or distilled water.

In using the apparatus, the platina plates are placed in these basins, and when the index points at 0° the operator places his hands in the basins so as to be well covered with water, and not to touch the plates of platina. After the deviations of the needle noticed by M. Remond have subsided, clench one hand, firmly contracting the muscles of that hand and arm to the shoulder, keeping those of the left hand and arm relaxed. The index will move 4° or 6°. When the other hand is clenched similarly, the index will move in the opposite direction to 4° or 6° on the other side of 0°. By continuing this process the deviation of the needle may amount to 14° or 16°. Mr Rutter has found that children of both sexes can deflect the needle with as much force as adults.

By forcibly extending the fingers of the hand in place of clenching it, and at the same time contracting the muscles of the hand and arm, Mr Rutter has found that the needle is deflected in a direction opposite to that when the hand is clenched. The force, however, is not so great as when the hands are clenched. In order to increase the sensibility of his galvanoscope he occasionally uses an electro-magnet.[1]

Art. 2. *On the Electricity of the Raia Torpedo.*

Electricity of the torpedo.

The remarkable property of giving an electrical shock possessed by this fish was known in the time of Aristotle and Pliny, and has been distinctly described by Appian. Redi, Reaumur, Kæmpfer, and Bancroft, successively described the phenomena which it exhibited; and Lorenzini, so early as 1678, published good engravings of the electrical organs of the torpedo.

Experiments of Walsh.

The first person, however, who made accurate experiments on the torpedo was Mr Walsh. He confirmed the remarkable observation of Kæmpfer, that the shock could be evaded if the person who touched the animal held in his breath at the time. Mr Walsh made two series of experiments on this fish, one when it was placed in the air, and the other in the water. In the first series he placed a living torpedo upon a table covered with a wet napkin, round which stood five persons who were insulated. Having suspended from the ceiling by strings two brass wires, each thirteen feet long, one of them was made to communicate by one extremity with the wet napkin, while its other extremity was plunged in a basin of water placed upon a second table, on which other four basins of water stood. The first of the five insulated persons plunged a finger of one hand in the basin in which the above-mentioned wire was placed, and a finger of the other hand into the second basin. The second person put a finger of one hand in this second basin, and a finger of the other in a third basin, and so on till the five persons formed a communication with each other by the water in the basins. The end of the second wire was plunged in the last basin, and Mr Walsh having taken the other end of this wire in his hand, touched the back of the torpedo, when all the five persons experienced a shock which differed only in force from that of the Leyden jar. The shock seldom extended beyond the touching finger, and out of 200 only one reached above the elbow. When the torpedo was insulated, it gave forty or fifty shocks to insulated persons, without any diminution of its force. Mr Walsh found that the shock was communicable through iron wires and other conductors, but not through air, glass, and other electrics; and he was never able either to produce a shock, or move the pith balls of an electrometer. In the series of experiments in water, Mr Walsh held a large and powerful torpedo in both hands by its electric organs, and after plunging it about a foot under water, he raised it suddenly to the same height in air. The instant the lower surface of the fish touched the water in descending, he received a violent shock, and the instant the same surface quitted the water in ascending, he experienced a still more violent shock. A writhing of the fish accompanied both these shocks, particularly the last. The intensity of the shock under water was scarcely one-fourth of that at the surface, and not much more than one-fourth of those given in the air. The number of shocks in a minute was about twenty, generally two and always one when he was wholly in the air, and sometimes two when he was below water. When the finger of one hand touched

[1] See Mr Rutter's *Human Electricity*, chap. vii., Lond. 1854.

Phenomena and Laws.

the upper part, and the thumb of the same hand the lower part, of a single organ, the shock was twice as great as when it passed through the arms, and Mr Walsh concluded that the two sides of the fish are in opposite electrical states.

Experiments of Ingenhousz;

Dr Ingenhousz, who repeated and confirmed these experiments, says that the sensation of the shocks is the same as if a great number of very small electrical bottles were discharged very quickly through the hand. M. Spallanzani found the shocks strongest when the fish was laid upon a plate of glass. When the animal was dying the shocks were not given at intervals, but resembled a continual battery of small shocks. The battery continued seven minutes, and in this time he experienced 316 shocks. Spallanzani also found that the fœtus gave perceptible shocks like the full-grown fish.

of Humboldt and Gay Lussac.

In the year 1805, MM. Humboldt and Gay Lussac examined the properties of the torpedo at Naples, but they do not seem to have added much to the observations made by Mr Walsh. They found that a person accustomed to electric shocks could with some difficulty support the shock of a vigorous torpedo fourteen inches long; that before each shock there is a convulsive movement of the pectoral fins; that the animal must be irritated previous to the shock; that the shock may be felt when a single finger is applied to a single surface of the electric organ; that an insulated person will not receive a shock if he touches the fish with a key or any other conducting body; and that the least injury done to the brain of the fish prevents its electrical action.

Electrical organs.

At the request of Mr Walsh, Dr Hunter, the celebrated anatomist, examined the electrical organs of a torpedo about eighteen inches long, twelve broad, and two thick. These organs are placed on each side of the cranium and gills, reaching from thence to the semicircular cartilages of each great fin, and extending in length from the anterior extremity of the animal to the transverse cartilage which divides the thorax from the abdomen. Within these limits the organs occupy all the space between the skin of the upper and outer surfaces. This description will be understood from fig. 1 of Plate CCXXVI., which represents a female torpedo, the skin B having been flayed from the under surface of the fish, to show the electric organs A. The nostrils, in the form of a crescent, are shown at *c*, and the mouth, having a crescent form, opposite to the nostrils, at *d*. The mouth is furnished with several rows of small hooked teeth. The bronchial apertures are shown at E, five being on each side; F is the place of the heart, *gggg* the place of the anterior transverse cartilages, *hh* the exterior margin of the great lateral fin, *i* its inner margin on the confines of the electrical organ, *l* the abdomen, *mmm* the place of the posterior transverse cartilage, which is single, united with the spine, and sustains the smaller lateral fins *nnnn* on each side; O is the anus, and P the fin of the tail.

Plate CCXXVI., fig. 1.

Each organ is about five inches long, and about three inches broad at the anterior end, and half an inch at the posterior extremity. Each organ consists wholly of perpendicular columns reaching from the upper to the under surface of the body, and varying in their lengths according to the thickness of the parts of the body where they are placed. The longest column is about one and a half inch, the shortest about one-fourth of an inch, and their diameter about two-tenths of an inch. The figures of the columns are irregular hexagons or pentagons, and sometimes have the appearance of being quadrangular or cylindrical. The number of columns in the fish examined by Dr Hunter was 470 in each organ; but in a very large fish four and a half feet long, and weighing seventy-three pounds, the number was 1182 in each organ. The number of partitions in a column one inch long was 150. The nerves inserted into each electric organ arise by three very large trunks from the lateral and posterior part of the brain; and when they have entered the organs they ramify in every direction between the columns, and send in small branches on each partition, where they are lost. Dr Hunter remarks that there is no part of any animal with which he is acquainted, however strong and constant its natural action, which has so great a proportion of nerves; and he hence concludes that, if it be probable that these nerves are not necessary for the purposes of sensation or action, they are subservient to the formation, collection, or management of the electric fluid.

M. Geoffroy de St Hilaire has more recently examined the torpedo. He analysed the fluid in the cells of the hexagonal columns, and found it to consist of albumen and gelatine; and, what is very curious, he discovered organs analogous to those of the torpedo in other species of the same genus Raia, which do not possess any electrical power.

Observations and experiments of Mr Todd.

Some useful observations were made upon the torpedo of the Cape of Good Hope in 1812 by Mr John T. Todd. The torpedos of this locality are never more than eight, nor less than five inches in length, and never more than five, nor less than three and a half inches in breadth. The columns of their electrical organs were larger and less numerous in proportion than those described by Hunter, and they appeared to be of a cylindrical form. The shocks of these torpedos were never sensible above the shoulder, and seldom above the elbow joint. The electrical discharge was generally accompanied by an evident muscular action, as shown by an apparent swelling of the superior surface of the electrical organs. From a great variety of experiments, which we have not room to enumerate, Mr Todd drew the following conclusions:—

1. That the electrical discharge is a vital action dependent on the life of the animal.

2. That the action of the electrical organ is entirely voluntary.

3. That frequent action of them is injurious to its life, and, if continued, deprives the animal of it.

4. That when the nerves and the organs are cut, the torpedo loses the power of giving a shock, though it appears more vivacious, and lives longer, than those in which this change has not been produced, and in which the electrical power is exerted.

5. That the possession of one organ only is sufficient to produce the shock.

6. That the perfect state of all the nerves of the electrical organs is not necessary to the production of the shock.

7. That (as was shown by Dr Hunter) a more intimate relation exists between the nervous system and electrical organs of the torpedo, both as to structure and functions, than between the same and any organs of any animal with which we are acquainted.

In 1816 Mr Todd made another series of experiments at La Rochelle, principally with the view of determining whether the torpedo possessed any voluntary power over the electrical organs, either in exciting or interrupting their action, except through the nerves of these organs. Shocks were given by the torpedo even when one half of each electrical organ was removed; and also when an incision was made extending round the circumference of both organs, so as to leave no attachment between these organs and the animal except the nerves. When the large lateral cartilages were removed, and a large portion of the surfaces of the electrical organs denuded, two distinct shocks were received; but the fish being much injured, soon died. During these experiments, Mr Todd observed how powerfully the action of the electrical organs was excited by the cutting of the scalpel; and on one occasion, when he pressed on the electrical organ with his left hand, and held the scalpel wet in the other while cutting the electrical organ,

Phenomena and Laws.

he received a distinct shock in the right hand through the scalpel. He observed also that all the nerves of the electrical organs arise from the medulla oblongata, notwithstanding the long course which three of them are obliged to follow.

Mr Todd informs us that the torpedo called *la tremble*, which occurs on the coast between the Loire and the Garonne, is eaten by the poorer inhabitants, who carefully avoid the electrical organs, which are supposed to possess some disagreeable properties.

Observations and experiments of Sir H. Davy;

In 1814 and 1815, when Sir H. Davy was on the shores of the Mediterranean, he was desirous of ascertaining whether or not the electricity of the torpedo possessed the chemical and magnetic powers of that agent. In both these trials he could neither decompose water, nor influence a highly delicate magnetic electrometer; and he seems disposed to infer that there is a stronger analogy between the common and animal electricity than between common and voltaic electricity, and that it is probable that animal electricity will be found to be of a distinctive and peculiar kind.

This eminent chemist intended to pursue these inquiries, but his ill health prevented him; and in his latest illness he requested his brother, Dr John Davy, to carry on the investigation. Dr Davy accordingly pursued the inquiry at Malta, and succeeded in obtaining several important results. He placed a needle perfectly free from magnetism within a fine copper spiral wire one and a half inch long and one-tenth of an inch in diameter, containing about 180 convolutions, and weighing about four and a half grains. By the electricity of a torpedo about six inches long, he succeeded in communicating distinct magnetism to this needle; and he repeated the experiment with the same success with fishes of different sizes. Dr Davy likewise succeeded in throwing into violent motion the needle of a magnetic multiplier. With every fish he tried he obtained decisive results, and he met with no instance of a fish which had the power of magnetizing a needle in the spiral wire failing to move the needle in the multiplier, though he met with more than one example of a fish whose electricity was equal to the latter effect and not to the former. Dr Davy, however, failed in obtaining any igniting power, or the faintest spark, by means of the torpedo. He also found that air was not impermeable to the electricity of the torpedo; but he never could exhibit any influence on the electrometer, or any indications of attraction and repulsion in air. Dr Davy's experiments on the chemical agency of this species of electricity were highly satisfactory. He decomposed strong solutions of common salt, nitrate of silver, and superacetate of lead, and he inferred that the *under* surface of the organ corresponds to the zinc, and the upper surface to the copper extremity of the voltaic battery. In the deviation of the needle in the multiplier produced by the torpedo, the action of its under surface corresponded with the zinc plate, and that of the upper surface with the action of the copper plate. In like manner, the extremity of a needle that received polarity from a torpedo when placed in a spiral wire, had *southern* polarity when it was nearest the *under* surface of the fish, and the other extremity of course *northern*. In one experiment Dr Davy connected the spiral with the multiplier, and having charged the former with eight needles, a single discharge from an active fish moved the needle in the multiplier powerfully, and converted all the needles into magnets. each of them as strong if one only had been used.

of Dr John Davy.

Chemical and magnetical effects.

Substance of its organs.

Dr Davy's next object was to ascertain "the exact nature of the substance of the electrical organs, or the peculiar structure of which they are composed." The electrical organs when wet weighed only 302 grains; and when completely dried by sixteen hours exposure to the boiling heat of water, they weighed only twenty-two grains. They appeared to him to consist of 7·28 of matter not evaporable at 212°, and of 92·72 water. When the electrical organs are immersed in boiling water, they suddenly contract in all their dimensions, and the columns, from pentagonal, which they generally are, become circular. The electricity of a small voltaic trough, the shock of which was just perceptible, distinctly affected the voluntary muscles of the live torpedo, but did not in the least affect the electrical organs. Their substances appeared to be neither sensitive nor contractile by the application of other stimulants; and hence he infers that these organs "are not muscular, but columns formed of tendinous and nervous fibres, distended by a thin gelatinous fluid." Dr Davy never could observe satisfactorily in the fresh fish the horizonal partitions which Dr Hunter had counted. After describing more fully and accurately than Dr Hunter the distribution of the three great trunks of the nervous system, Dr Davy describes the mucous system, which forms a conspicuous part of the anatomical structure of the fish. It consists of several clusters and chains of glands, distributed chiefly around the electrical organs, at different depths beneath the cutis, and of strong transparent vessels of various lengths and sizes opening externally in the skin for the purpose of pouring out the thick mucus secreted by the glands, and destined for lubricating the surface. This system, which was not noticed by Dr Hunter, was described, but imperfectly, by Lorenzini. Dr Davy thinks that this system may not only be aided by, but also aid the secretion of the mucus. In comparing the phenomena of the torpedo with those of other kinds of electricity, Dr Davy notices the following points of difference:—"Compared with voltaic electricity, its effect on the multiplier is feeble; its power of decomposing water and metallic solutions is inconsiderable; but its power of giving a shock is great, and so also is its power of magnetizing iron. Compared with common electricity, it has a power of affecting the multiplier, which, under ordinary circumstances, common electricity does not exhibit; its chemical effects are more distinct; its power of magnetizing iron and giving a shock appears very similar; its power of passing through air is infinitely less as is also (if it possess it at all) its power of producing heat and light."

Experiments of Dr Davy;

of Cavendish.

These differences have been explained in different ways by different authors. Mr Cavendish endeavoured to account for them on the principles of common electricity. Mr Nicholson did the same with much ingenuity. Volta at first supposed that the superposition of the different cells in the columns, formed of substances some of which excite electricity by contact, while others transmit it, corresponds to that of the metallic and moist conductors of which the pile is composed; but he afterwards showed to Sir H. Davy another form of the pile, which he thought fulfilled the conditions of the organs of the torpedo; a pile of which the fluid substance was a very imperfect conductor, such as honey, or a strong saccharine extract, which required a certain time to be charged, and which, though it did not decompose water, communicated nevertheless weak shocks when charged. MM. Humboldt and Gay Lussac were more inclined to compare the action of the torpedo to a chain of small Leyden phials, like Cavendish, than to the voltaic pile. In order to explain why no spark is given by the torpedo, Mr Cavendish proved by experiment that the distance through which the spark flies is inversely (or rather in a greater proportion) as the square root of the number of jars; and hence the torpedo may contain sufficient electricity to give a shock, without being able to make it pass through such a space of air as is requisite for the production of the spark. He accounted also for the absence of every appearance of attraction and repulsion, from the known fact that the shock of a battery so weakly electrified as to be incapable of passing through a chain, which is the case with the electricity of the torpedo, is not capable of producing

Phenomena and Laws.

any divergency in the pith balls of an electrometer. Mr Cavendish corroborated these views by constructing an artificial torpedo of thick leather, connected with glass tubes and wires, and covered with a piece of sheep-skin leather, which was an exact imitation of the real torpedo. The battery was composed of forty-nine jars of very thin glass, and contained about seventy-six feet of coated surface.

Humboldt has enumerated the following species of the torpedo which are electrical:—Torpedo narke, *Risso;* Torpedo unimaculata; Torpedo marmorata; Torpedo Galvanii.

It is very difficult to preserve the torpedo for experiments. Dr Davy could not keep them alive for twelve or fifteen days; and M. Matteucci could not preserve one out of 116 above three days, though the greatest attention was paid to them.

Art. 3.—*On the Electricity of the Gymnotus electricus.*

Electricity of the gymnotus.

The electrical eel of Surinam, or *Gymnotus electricus*, possesses electrical organs different from those of the torpedo, and exhibits different electrical properties. Its common size is about *three* feet in length; though Dr Bancroft was told that some have been seen in the Surinam river upwards of twenty feet long, and whose shock proved immediately fatal.

Richer was the first person who made known in Europe the electrical properties of this fish; and experiments have been since made upon it by various naturalists. It is from the observations, however, of Dr Williamson of Philadelphia, Dr Garden of Charlestown, and Mr Walsh, that our knowledge of its properties is derived; and these may be summed up in the following manner:—

1. When the gymnotus is touched by the hand, a shock is felt in the fingers, and often as far up as the wrist and elbow; and when it is touched with an iron rod twelve inches long, the shock is felt in the finger and thumb.

2. If the eel is provoked by one person, the hand of another person held in the water will experience a small shock.

3. When the eel was touched and provoked with one hand, and the other held in the water at a small distance, a shock passed through both arms; and the same effect was produced when the hand held a wet stick in the water; and when the same experiment was made by eight or ten persons who joined hands, a shock was also experienced.

4. When the first of eight persons pinched the tail, while the last touched the head, they all experienced a severe shock.

5. The shock of the eel was found to pass through those substances which are conductors, and to be stopped by those which are non-conductors, of common electricity.

6. An insulated person electrified, exhibited no marks of electricity; and pith balls refused to diverge either when suspended over the eel's back, or touched by an insulated person when he received the shock.

7. Dr Williamson succeeded in making the electricity of the eel pass through a small space of air, and exhibit the electric spark when the fish was in the open air; but the spark is not visible when the fish is placed in water.

In the preceding experiments the gymnotus was in a large vessel, supported by pieces of dry timber about three feet above the floor. A small hole having been bored in the vessel, a person who held his finger in the stream of water which flowed from it experienced a shock when the eel was irritated.

Dr Williamson threw a cat fish into the same vessel with the gymnotus, and in a short time it gave the cat fish a shock, and caused it to turn up its belly and remain motionless.

Observations of Fahlberg.

Experiments on the gymnotus have more recently been made by M. Fahlberg of Stockholm, and by MM. Humboldt and Bonpland. The Swedish philosopher succeeded in obtaining an electric spark from the eel when placed in the air, by interrupting the conducting chain by two gold leaves pasted upon glass, and a line distant from each other; but he never could discover any phenomenon of attraction or repulsion, though he employed very delicate electrometers, and caused very strong shocks to pass through them.

Of Humboldt and Bonpland.

While MM. Humboldt and Bonpland were in South America, where the little streams, and even the basins of stagnant water, are filled with electrical eels, they enjoyed the finest opportunities of studying the phenomena of their electrical action. Having imprudently placed both his feet on a fresh gymnotus, Humboldt experienced a more dreadful shock than he ever received from a Leyden phial, and which left a violent pain in his knees, and in almost every joint, during the rest of the day. When both he and M. Bonpland held a fish, the one by the head or by the middle of the body, and the other by the tail, and, standing on the ground, did not join hands, one of them received shocks which the other did not feel; and hence they concluded that the eel could direct its strokes where it chose, or towards the point where it was most strongly irritated, sometimes discharging them from the whole surface of its body, and sometimes from one point only.

The gymnoti that had been rendered extremely tame during their voyage from Surinam to Stockholm were made to fast a long time, and when fishes were put into the tub they killed them at a distance, the electrical stroke passing through a very thick stratum of water. A fresh-caught gymnotus was placed by Humboldt beside little tortoises and frogs, which, ignorant of their danger, placed themselves upon its back. The frogs did not receive the shock till they touched the body of the eel. When they recovered they leapt out of the tub. Humboldt remarks that this gymnotus was not yet sufficiently tamed to attack and devour frogs.

Upon cutting a very vigorous fish through the middle of the body, Humboldt observed that the fore part alone gave shocks. The shocks, however, are equally strong in whatever part of the body the fish is touched, though it is most disposed to dart them forth when the pectoral fins, the electrical organ, the lips, the eyes, or the gills are pinched. Humboldt remarks that no person has ever perceived a spark issue from the body of the fish itself. He irritated it for a long time during the night, at Calabozo, in perfect darkness, without observing any luminous appearance.

Method of fishing the gymnoti with horses.

The method of fishing the electrical eels by horses, as described by Humboldt, is too interesting to be omitted in a popular article. The Indians having brought about thirty wild horses, forced them to enter a pool of muddy water surrounded with fir trees. "The extraordinary noise caused by the horses' hoofs makes the fish issue from the mud, and excites them to combat. These yellowish and livid eels, resembling large aquatic serpents, swim on the surface of the water, and crowd under the bellies of the horses and mules. A contest between animals of so different an organization furnishes a very striking spectacle. The Indians, provided with harpoons and long slender reeds, surround the pool closely, and some climb upon the trees, the branches of which extend horizontally over the surface of the water. By their wild cries, and the length of their reeds, they prevent the horses from running away, and reaching the banks of the pool. The eels, stunned by the noise, defend themselves by the repeated discharge of their electric batteries. During a long time they seem to prove victorious. Several horses sink beneath the violence of the invisible strokes which they receive from all sides in organs the most essential to life, and, stunned by the force and frequency of the shocks, disappear under the water. Others, panting, with with mane erect, and haggard eyes expressing anguish, raise

Phenomena and Laws.

themselves, and endeavour to flee from the storm by which they are overtaken. They are driven back by the Indians into the middle of the water; but a small number succeed in eluding the active vigilance of the fishermen. These regain the shore, stumbling at every step, and stretch themselves on the sand exhausted with fatigue, and their limbs benumbed by the electric shock of the gymnoti.

"In less than five minutes two horses were drowned. The eel being five feet long, and pressing itself against the belly of the horses, makes a discharge along the whole extent of its electric organ. It attacks at once the heart, the intestines, and the *plexus cœliacus* of the abdominal nerves. It is natural that the effect felt by the horses should be more powerful than that produced upon man by the touch of the same fish at only one of its extremities. The horses are probably not killed, but only stunned. They are drowned from the impossibility of rising amid the prolonged struggle between the other horses and the eels.

"We had little doubt that the fishing would terminate by killing successively all the animals engaged; but by degrees the impetuosity of this unequal combat diminished, and the wearied gymnoti dispersed. They require a long rest and abundant nourishment to repair what they have lost of galvanic force. The mules and horses appear less frightened: their manes are no longer bristled, and their eyes express less dread. The gymnoti approach timidly the edge of the marsh, where they are taken by means of small harpoons fastened to long cords. When the cords are very dry the Indians feel no shock in raising the fish into the air. In a few minutes we obtained five large eels, the greater part of which were but slightly wounded. Some were taken by the same means towards the evening."

The gymnotus is the largest of the electrical fishes. A fish of three feet ten inches long, obtained by Humboldt, weighed twelve pounds. The transverse diameter of the body was three inches five lines. The gymnoti of the *Cano de Bera* are of a fine olive-green colour. The under part of the head is yellow mingled with red. Two rows of small yellow spots are placed symmetrically along the back, from the head to the end of the tail. Every spot contains an excretory aperture, which keeps the skin of the animal covered with a mucous matter, which, as Volta has proved, conducts electricity twenty or thirty times better than pure water.[1]

Electrical organs of the gymnotus. Plate CCXXVI., fig. 2.

Dr Hunter examined, with his usual skill, the electrical organs of this fish; and in fig. 2 we have copied his engraving of it, in which the skin is removed to show the structure. In this figure A represents the lower surface of the head; C, the cavity of the belly; B, the anus; E, the back, where the skin remains; GG, the fin along the lower edge of the fish; EE, the lateral muscles of this fin, removed and laid back with the skin to expose the small organs; L, part of the muscle left in its place; FF, the large electrical organ; HHH, the small electrical organs; *mmm*, the substance which separates the two organs; and *n*, the place where this substance is removed. These organs occupy nearly one-half of the part of the flesh in which they are placed, and form more than one-third of the whole fish. There are two pairs of electrical organs of different sizes, and placed on different sides; the large one F occupies the whole of the lower and lateral part of the fish, constituting the thickness of its fore part, and extending from the abdomen to near one end of the tail, where it terminates nearly in a point. The two organs are separated at the upper part by the muscles of the back, at the lower part by the middle partition, and by the air bag at the middle part. The lesser organ stretches along the lower edge of the fish, and nearly as far as the other, terminating almost insensibly near the end of the tail. The two small organs are separated from each other by the middle muscle, and by the bones in which the fins are articulated. The large organ may be seen by merely removing the skin, which adheres to it by a loose cellular membrane; but in order to see the small organ, the long row of small muscles which move the fin must be removed. The electrical organs consist of two parts, viz. flat partitions of septa, and thin plates or membranes intersecting them transversely. The septa are thin parallel membranes stretching in the direction of the fish's length, and as broad as the semidiameter of the animal's body. The septa vary in length, some of them being as long as the whole body. In a fish two feet four inches long, the distance of the septa was nearly half an inch; and in the broadest part of the organ, which was one and a quarter inch, there were thirty-four septa. In the small organ the septa have a somewhat serpentine direction. They are only the fiftieth of an inch distant, and there are fourteen septa in the breadth of the organ, which is half an inch. The very thin plates which intersect the septa have their breadth equal to the distance between any two septa. There is a regular series of these plates from one end of any two septa to the other end, 240 of them occupying a single inch.

Dr Faraday's experiments.

A number of interesting results were obtained in 1838 with a gymnotus by Dr Faraday. The fish was caught in March 1838. It was brought to the Adelaide Gallery on the 15th of August, but did not feed from the time of its capture up to the 19th of October, when it killed and eat four small fish. It subsequently ate one gudgeon, carp, or perch daily. Dr Faraday obtained from the electricity of this gymnotus the electric spark, chemical decomposition, and the evolution of heat. It deflected the needle of a galvanometer, and he made magnets with it. He failed, however, in producing the attraction of gold leaves. The shock of the gymnotus was most powerful when one hand was placed on the body near the head, and the other near the tail. It resembled "that of a large Leyden battery, charged to a low degree, or that of a good voltaic battery of perhaps one hundred or more pairs of plates, of which the circuit is completed for a moment only." Dr Faraday concluded from his experiments that "a single medium discharge of the fish is at least equal to the electricity of a Leyden battery of fifteen jars, containing 3500 square inches of glass, coated on both sides and charged to its highest degree;" and, great as this force is, he frequently experienced it to give two and even three shocks with scarcely a sensible interval of time between them. When the fish wills the shock, the *anterior* parts are *positive*, and the *posterior* parts *negative*.

The following results were obtained by Dr Faraday, and will be understood from the annexed diagram, where AB is the tub containing the animal, supported upon dry wooden logs. It was 46 inches in diameter, with a depth of water in it of $3\frac{1}{2}$ inches. The numbers show the places where the hands were put; those across the fish implying that the hands touched it: the letters A,B,C are three different experimenters, A being the person who excited the fish to action.

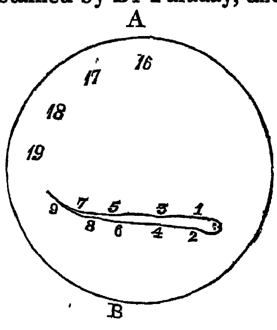

Fig. 7.

When one hand was in the water a weak shock was felt only in it, whatever part of the fish it touched, and only in the part immersed. When both hands were in the water at the same parts of the fish, a weak shock was felt only in the parts immersed.

When both hands were at 1, 3, or 4, 6, or 3, 6, strong

[1] Humboldt notices it as remarkable that no electrical fish is covered with scales.

Phenomena and Laws.

shocks extended up the arms and even to the breast. The shock was strongest at 1, 8, and perceptible at 8, 9.

When B's hands were at 10, 11, four inches from the fish, whilst A excited it with a glass rod, B received a powerful shock. When A was at 4, 6, B at 10, 11, C at 16, 17, and D at 18, 19, they all received shocks at the same time, A and B strongly, and C and D feebly.

When B had both hands at 10, 11, or at 14, 15, whilst A had but one hand at 1, or 3, or 6, the former got a strong shock, and the latter a weak one.

When A's hands were at 3, 5, B's at 14, 15, and C's at 16, 17, A's shock was the most powerful, B's the next, and C's the feeblest.

When A excited the fish with his hands at 8, 9, whilst B was at 10, 11, B had a stronger shock than A.

When A excited the fish with one hand at 3, B with both hands at 10, 11 (or along), and C had the hands at 12, 13 (or across), A felt a pricking shock in the immersed hand only, B a strong shock up the arms, and C but a slight effect in the immersed parts.

Dr Faraday concludes from all the experiments he has made that "all the water and all the conducting matter around the fish, through which a discharge circuit can in any way be completed, is filled at the moment with circulating electric power. "This state," he adds, "might be easily represented generally in a diagram by drawing the lines of inductive action upon it. In the case of a gymnotus surrounded equally in all directions by water, these would resemble generally in disposition the magnetic curves of a magnet having the same straight or curved shape as the animal, that is, provided he in such cases employed, as may be expected, his four electric organs at once." [1]

Experiments of Matteucci.

The subject of electric fishes has been more recently studied by M. Matteucci of Pisa. The following are some of the results which he has obtained:—

1. When any part of the body of an electric fish is irritated, the irritation is transmitted by the nerves to the fourth lobe of the brain, and then only the electric discharge takes place.

2. An electric discharge is obtained by irritating a very small part of a prism of the electric organ of the torpedo.

3. The electric organ of the fish is a nervous fibril in contact with a small cell filled with albumen; and as this cell gives an electric shock when subjected to nervous action, the two opposite electricities must be separated to be instantaneously reunited.

4. Each prism of these electric organs is a pile of elementary organs upon each of which a nervous filament is spread normally to the axis of the pile, analogous to a cylinder of cast-iron inclosed in a helix of metallic wire, and traversed by the electric current.

5. The sum of the electric currents given by the different slices of the organ of a torpedo is approximately equal to the current given by the entire organ. In the gymnotus the strongest discharge is that which is obtained by including the entire length of the animal within the circuit.

6. The electric shock increases with the vital action of the torpedo. The shock is increased by raising a little the temperature of the water, and diminished by hindering respiration or circulation. It is diminished also after a number of shocks. It is increased by rest, and it becomes more powerful than usual when the fish is excited by nux vomica.[2]

Art. 4. *On the Electricity of the Silurus electricus.*

Silurus electricus, fig. 3.

The *Silurus electricus*, of which we have given a drawing in fig. 3, is a fish about twenty inches long, which is found in the Senegal, the Niger, and the Nile. It is eaten by the Egyptians, who dress its flesh, and salt its skin as an aphrodisiac medicine. The shock of this fish is distinctly felt when it is laid on one hand, and touched by an iron rod six feet long held in the other. Its electrical organs, according to M. Geoffroy, are much less complicated than those of other electrical fishes. They lie immediately below the skin, and stretch all round the body of the animal. Their substance is a reticulated mass, the meshes of which are clearly visible, and these cells are filled, like those of other electrical fishes, with an albuminous gelatinous matter. The nerves distributed over the electric organs proceed from the brain, and the two nerves of the eighth pair have a direction and nature peculiar to this species.

Art. 5. *On the Electricity of the Tetraodon electricus.*

Tetraodon electricus.

In the cavities of the coral rocks in Johanna, one of the Canary islands, Lieutenant Paterson discovered the *Tetraodon electricus*, which he found to possess the properties of other electrical fishes. It has a long projecting mouth, and is seven inches long and two and a half broad. The colour of its back is brown, of its belly sea-green, of its sides yellow, of its fins and tail sandy-green. Its body is covered with red, green, and bright white spots. It has large eyes, and its iris is red, tinged with yellow on its outer edges. It is found also in the American seas.

Lieutenant Paterson found this fish in water whose temperature was 56° or 60° Fahrenheit; and having caught two of them in a linen bag, he had no sooner taken one of them in his hand than he received so severe a shock that he was obliged to let it go. He carried the two fishes to the camp, and though one of them died, and the other was in a state of great debility, he was able to obtain the evidence of the surgeon and the adjutant in favour of his discovery. The former having held it between his hands, received a distinct electrical shock, and the latter received a shock by merely touching the fish on its back with his finger.

Art. 6. *On the Electricity of the Trichiurus electricus.*

Trichiurus electricus.

This fish, which we believe is the *Trichiurus indicus* of Shaw, inhabits the Indian seas, and has been found to possess the power of giving an electrical shock. It has a pointed snout, and belongs to the family Tænioides, of the order Acanthopterygii.

Other electrical fishes.

Other electrical fishes have been met with, but the descriptions given of them do not enable us to determine whether or not they are the same as those which we have described in this section. Mr Maxwell, in his observations on Congo and Loango, mentions his having found at sea an electrical fish, which made the sailor who took it exclaim "that the devil was in the fish." When examining it attentively, Mr Maxwell found that his astonishment arose from his having received an electrical shock. Before each shock the skin on his back and sides became very tense. It was like a cod, and weighed *thirty pounds.* He gave it to the natives to eat, and they praised it much. No electrical fish of such a size has, so far as we know, been found, and it is highly probable that it is a new species.

Sect. VI.—*On the Electricity of the Atmosphere.*

Electricity of the atmosphere.

There is perhaps no branch of electricity so highly interesting as that which treats of the electricity of the atmosphere, whether we consider it in reference to ourselves, as beings exposed to its tranquil as well as to its disturbed influence, or in reference to the grandeur and beauty of the phenomena which it exhibits.

[1] Faraday's *Experimental Researches, &c.*, vol. ii., p. 8, &c.

[2] See *Phil. Trans.*, 1847, p. 239, 241.

Phenomena and Laws.

The methods which have been adopted for examining the electricity of the atmosphere consist in elevating long vertical rods, the summits of which collect the electricity, or in extending insulated wires in a horizontal direction, or in sending up kites into the higher regions.

Experiments of Le Monnier and others;

M. le Monnier, the Abbé Mazeas, Mr Kinnersley, Beccaria, Saussure, Ronayne, Cavallo, Read, Crosse, Ronalds, Schubler, &c., have made numerous experiments on the electricity of the atmosphere in its ordinary state. Le Monnier discovered that there was always more or less electricity in the atmosphere; that there was a regular diurnal period in which the electricity increased from sunrise, when it was scarcely perceptible, till three or four o'clock in the afternoon, when it reached its maximum; and that it again diminished till the fall of the dew, when it again increased, and subsequently diminished, till midnight, when it became insensible.

of Beccaria;

M. Beccaria found that the electricity of the air was always perceptible in a clear sky and calm weather. In rainy weather, without lightning, it always appeared a short time before the rain fell, and during its actual fall, but disappeared soon after the rain had ceased.

of Saussure;

Saussure made many important observations on this subject. He found that the electricity of the air was very strong at nine o'clock in the morning; that it gradually diminished till six o'clock P.M., when the first minimum took place; that it afterwards increased to eight o'clock P.M., when the second maximum took place. It then diminished again with some irregularities till six A.M., when it reached its second minimum. It then increased again till eleven o'clock in the evening, when it again became a maximum. The electricity of the atmosphere has therefore a daily period, like the sea, increasing and decreasing twice in twenty-four hours. It, generally speaking, reaches its maximum intensity a few hours after sunrise and sunset, and descends again to its minimum before the rising and setting of that luminary. Saussure also observed that the electricity of the air is strongest during fogs, unless when they change into rain. Saussure likewise found that the electricity of clear weather is always positive; and the opinion of Volta is therefore highly probable, that the electricity of the atmosphere is essentially *positive*, and that the negative electricity which appears in rain, snow, and storms, is derived from more elevated clouds, which are electrified negatively by the discharge of a portion of their electricity into the earth or other clouds, in the same manner as an electrometer acquires negative electricity when it is touched at the instant that the air is electrified positively.

of Crosse;

These results were confirmed by subsequent observers, whose observations we have not room more particularly to notice; but we shall make no apology for giving some account of the more recent and valuable observations of Mr Crosse and Mr Ronalds. Mr Crosse's experiments were made with an insulated copper wire, extending originally a mile and a quarter in length, and supported upon two masts from 100 to 110 feet high. The wire was one-sixteenth of an inch thick. It was subsequently shortened to 1800 feet in consequence of its being exposed to depredations. From the observations made with this apparatus, which was in use eighteen months, Mr Crosse deduced the following conclusions.

1. The electricity of the atmosphere in its ordinary state is invariably *positive*. It is always most copious during the night. It increases at sunrise, diminishes towards noon, increases again towards sunset, and again diminishes to its nocturnal minimum.

2. The electrical state of the wire is disturbed by fogs, rain, hail, snow, and sleet. It becomes negative when they first come on. It frequently changes to positive, increasing gradually in strength, and then decreasing, a change from positive to negative occurring every three or four minutes.

3. The approach of a charged cloud at first sometimes produces positive and sometimes negative electricity. Its intensity increases and then diminishes and vanishes, being succeeded by the opposite electricity, which increases to a higher maximum, and then diminishes and disappears, and is again followed by the electricity which first appeared. In general the electricity increases at every repetition, till sparks issue in a copious stream from the conductor to the receiving ball, sometimes with interruptions, and again returning with fresh energy. When this happens, a powerful stream of air issues from the wire and the connecting apparatus. An explosive stream of electricity rushes from the one ball to the other at every flash of lightning, and a brilliant light is thrown upon surrounding objects. When the lightning increases, it is wise to let it pass into the ground.

4. The wire is almost as strongly electrified during a driving fog and a smart rain as during a thunder storm, and the electricity passes into opposite states in a similar manner.

5. A very feeble degree of positive electricity occurs in cloudy weather. When rain falls it changes to negative, and again becomes positive when the shower is over.

The following table contains a list of the different states of the air in which its electricity appears, those at the top of the list being those in which it is most powerful.

1. Regular thunder clouds.
2. Driving fog with small rain.
3. A fall of snow, or a brisk hail storm.
4. A smart shower in a hot day.
5. A smart shower in a cold day.
6. Hot weather after some wet days.
7. Wet weather after some dry days.
8. Clear frosty weather.
9. Clear warm summer weather.
10. A sky obscured by clouds.
11. Mackerel or mottled sky.
12. Sultry weather with light hazy clouds.
13. A cold damp night.
14. Weather during north-east winds, with a sensation of dryness and cold not shown by the thermometer.

Experiments of Ronalds,

By means of an electrical apparatus, founded on a new method of electrical insulation, Mr Ronalds made some interesting observations on Vesuvius at the time of moderate eruptions, and another series at Palermo during the prevalence of a sirocco. The rod of the electrometer was placed perpendicularly on the highest pinnacle of Mount Vesuvius, on the north side of the great crater, and about five hundred yards distant from it, a ravine being interposed. The following were the results:

1. The electricity was *always* positive.

on Vesuvius;

2. The intensity of it increased as the sun rose, unless when it was affected by the explosions of the volcano. Very frequent variations took place in the intensity, sometimes accompanying changes of the wind, sometimes following explosions from the crater, sometimes attending the approach of vapour from an aqueous fumerole, when the intensity of the electricity was always increased, and sometimes occurring without any apparent cause.

3. The black fumes from the old crater diminished the intensity more frequently than the white fumes, and very rarely increased it. Mr Ronalds supposes that the black fumes may be in a negative state; and that the white fumes, consisting principally of aqueous vapour, sulphuric and muriatic acids, and sulphur, may, when these vapours are condensed, and when the sulphur sublimes in the air, be brought into a positive state; and that these two states of the two fumes may sometimes act separately on the electrometer, or sometimes wholly and sometimes partially neutralize each other, either by induction or position, or by a discharge from the one to the other.

at Palermo.

The observations of Mr Ronalds on the electricity of the atmosphere during a dry sirocco were made on the roof of

Phenomena and Laws.

Page's hotel, in Palermo. The electricity was always *positive*, the straw electrometer of Volta varying from five to twenty-one degrees. The electrical phenomena were diametrically opposite to those of the ordinary state of the atmosphere in serene weather, as the electric tension increases almost progressively from sunrise till the hottest part of the day, viz. about three o'clock P.M., when it gradually declined until sunset.

In the arctic regions in 1819–20, there were no sensible indications of electricity "in the summer months, when the clouds become more dense and frequent, and even when a slight shower of rain falls."

Observations of Schubler.

A series of most interesting observations have been made by Professor Schubler of Tubingen, on the electricity accompanying the condensation of aqueous vapours in the atmosphere, as affected by the direction of the winds. They were carried on during thirty months, between January 1805 and August 1811. The *first* series was made at Ellvanguen, during sixteen months, from January 1805 to April 1806; and the *second* at Stuttgard, during fourteen months, from June 1810 to August 1811. Ellvanguen is situated 1331 feet above the sea, in 48° 57′ 25″ of N. Lat., and Stuttgard at 847 feet, in N. Lat. 48° 46′ 32″. Professor Schubler observed no fewer than four hundred and twelve atmospherical precipitations. He used the straw electrometer of Volta, and a simple condenser; and in storms he never pushed his observations beyond the 600th degree of the instrument.

The following table contains the results of these observations.

Direction of the Winds corresponding to the Observations.	Number of observed Precipitations, classed according to the Nature of their Electricity.		Ratio of the Number of Positive and Negative Precipitations.	Mean Intensity of each of the two Electricities.		Mean Intensity of the Electricity, without considering its Nature.	Total Number of Precipitations observed.
	Positive.	Negative.		Positive.	Negative.		
North	12	11	100 : 91	131	99	116	23
North-east	11	12	100 : 109	105	132	120	23
East	3	5	100 : 166	15	13	13	8
South-east	4	7	100 : 175	19	10	13	11
South	5	13	100 : 260	26	23	24	18
South-west	28	65	100 : 232	66	33	44	93
West	73	106	100 : 145	75	39	53	179
North-west	25	32	100 : 128	31	46	40	57
The three north winds, N.W.—N.—N.E.	48	55	100 : 114	74	75	75	103
The three south winds, S.E.—S.—S.W.	37	85	100 : 230	57	26	39	122
The three west winds, S.W.—W.—N.W.	126	203	100 : 161	57	38	48	329
The three east winds, N.E.—E.—S.E.	18	24	100 : 133	71	72	72	42
All the winds	161	251	100 : 155	69	43	53	412

From these observations Professor Schubler draws the following conclusions:—

1. The ratio of the *positive* to the *negative* precipitations follows a regular variation, setting out from the north or south wind, and proceeding either by the *east* or *west* winds.

2. By a *north* wind, the positive precipitations are a little more frequent than the negative ones; by a *south* wind, the *negative* precipitations are more than *double* the *positive* ones.

3. The negative precipitations, by the three south winds, viz. south-east, south, and south-west, are double those by the three *north* winds, viz. north-west, north, and north-east, the ratio being 114 to 230.

4. The *east* and *west* winds hold a mean in this respect. The *former*, however, approach more to those of the *north*, and the *latter* to those of the *south*, the electricity being oftener *negative* by the three *west* winds than by the three *east* winds in the ratio of 161 to 133.

5. The electricity of all the observed precipitations is oftener negative than positive in the ratio of 155 to 100.

6. The mean intensity of the *positive* electricity is, on the contrary, more considerable than that of the *negative* in the ratio of 69 to 43.[1]

7. The intensity of the electricity, abstraction being made of its nature, is the *strongest* by the three north winds, particularly the north-east and north.

8. The electricity is at an average the weakest by the three south winds. Its intensity is by these three winds in the ratio of 39 to 75 weaker than by the three *north* winds.

9. By the three east winds the electricity is in the ratio of 72 to 48 stronger than by the three west winds.

10. The mean intensity of the electricity of all the precipitations, whether positive or negative, observed *in all directions of the winds*, is almost the same as that of the electricity of the precipitations observed *during the west winds alone*.

11. During the *north* and *east* winds the opposite electricities appear most distinctly, and almost with equal intensities. The *west* winds, and particularly the *south*, exhibit, on the contrary, a more feeble electricity, but a greater number of negative precipitations.

12. The *greatest* number of electrical precipitations takes place during *west* winds, and the *least* during *east* winds. The mean direction of the wind during the whole of the precipitations is 86°·9, making use of the formula of Lambert, in which the south is marked by 0°, the west by 90°, the north by 180°, and the east by 270°. The number 86°·9 corresponds with the WEST, with four degrees of declination to the south-west.

With respect to the cause of the phenomena now described, Professor Schubler is of opinion, that at the moment of the precipitation of the vapours in our atmosphere, *positive* electricity is at first developed, and the *negative* appears to arise most frequently from the influence of the former. The precipitations which first take place during storms, or passing rains and snows, are commonly *positive*, and are soon followed with *negative* ones of nearly equal in-

[1] Considering the quantity of the two electricities as made up of their intensity and the number of times that either of them is observed, the ratio of the quantities of positive and negative electricity observed will be 690 or 666, nearly that of equality.

Phenomena and Laws.

tensity. This alternation often happens several times, during which the drops of rain, hailstones, sleet, and snow, continually vary in their size, density, and continuity. At last the electricity, growing weaker and weaker, ends by remaining negative; and sometimes after the storm a rain falls with negative electricity.

Observations of Schubler.

It is, however, not uncommon to see regular and continuous rains *negative* from their commencement, and during whole days. This fact, together with the feeble intensity of this kind of electricity, seems to favour the opinion that it is often owing to the partial evaporation experienced by the drops of rain during their fall.[1] In confirmation of this he adduces the fact of the negative electricity of the fine aqueous dust at the foot of cascades, which is sometimes so strong in large waterfalls as to make the electrometer diverge more than 100 degrees.

This explanation, Professor Schubler alleges, agrees also with the great frequency of *negative* rains in *south* winds, and of *positive* ones in *north* winds. A current of warmer air, and consequently more light and more elevated, in the first case ought to facilitate the evaporation of drops of rain during their fall; whilst, by the colder north wind, and consequently more heavy and nearer the surface of the earth, the clouds have in general a lower position, and the evaporation of the drops of rain is less easy, and almost nothing.

From these observations it also follows that we must not infer the negative state of the cloud from the negative electricity of the rain which falls from it; for it may happen that rain coming from clouds slightly positive may become negative by the partial evaporation of the falling drops.

M. Schubler also remarks, that the great intensity of the electricity, and the distinct manner in which the two electrical principles alternately predominate during *north* and *east* winds, seem to arise chiefly from the dryness of the air during their continuance; to which we must add the situation of the clouds brought by these winds near the surface of the earth, the electricity of which may then naturally exert a more sensible influence upon our instruments.

Observations of Gay Lussac and Biot.

The positive electricity of the atmosphere was found by Saussure to increase in intensity in proportion to the height at which it was collected. When MM. Gay Lussac and Biot ascended in a balloon, they collected atmospheric electricity from the clouds below them, by suspending a wire about 160 feet long from the balloon, and stretching it with a ball of metal. The electricity collected at the upper end of this thread was very perceptible in their electroscope; and when it was examined with a stick of sealing-wax it was found to be *resinous* or *negative*, although the weather was perfectly serene. This result, though apparently inconsistent with the observations of Saussure and others, has been shown by M. Biot to be perfectly reconcilable with them.

Plate CCXXVI., fig. 4.

In fig. 4, Plate CCXXVI., let WW′ be the wire, let us call A the stratum of atmosphere through which the wire passes, B the stratum above this, and C the stratum below it; and let us suppose, what is true, that the atmosphere has positive electricity, which increases with the height. The *positive* electricity in the superior stratum A will attract the *negative* electricity of the wire WW′ with a force equal to $+ P$, and will repel the positive electricity of WW′ with a force equal to $+ N$. The positive electricity in the lower stratum C will do the very same, but in an opposite direction, and with an inferior degree of force, viz. $+ p$ and $+ n$, since the electricity increases with the altitude. Hence it follows that the negative electricity of the wire will be attracted towards its upper end by an excess of force equal to $P - p$, and the positive electricity will be repelled to its lower end with an excess of force $N - n$. To MM. Gay Lussac and Biot, therefore, who observed the electricity of the wire at its upper end, the electricity should be *negative;* and to M. Saussure and others, who observed it at its lower end, it should be *positive.*

Experiment of Hermann.

Upon the same principle, M. Biot explains a very interesting experiment made by M. Hermann. A very sensible electroscope with gold leaves is fixed at a certain height in the atmosphere when the weather is clear, and it there gives no perceptible indications of electricity. A metallic wire, or any other conductor, placed horizontally at the end of an insulating rod, is then placed and kept a short time in a stratum of air a few feet only above the electroscope. It is afterwards quickly brought down so as to touch the electroscope, and the gold leaves diverge with *vitreous* or *positive* electricity; but if, on the contrary, the insulated wire is placed and kept a short time in a stratum of air below the electroscope, and is then quickly raised and made to touch the electroscope, the leaves will diverge with negative electricity.

explained by Biot.

In order to explain these opposite results, we must consider that the insulated conductor is charged at each time with the degree of electricity which belongs to the stratum in which it is placed. When it is carried rapidly, therefore, so that its state is not quite destroyed by the contact of the molecules of air among which it is placed, it will communicate this state to the electroscope. If it comes from *above*, it will carry to it an excess of *positive* electricity; if it comes from *below*, it will carry to it a defect of the same electricity, or an excess of *negative* electricity. "In general," says M. Biot, "let $+ E$ be the quantity of free vitreous electricity which the insulated conductor ought to possess, in order to be in a state of electrical equilibrium in the stratum of air where the electroscope is placed, so that whilst it has $+ E$, the molecules of air of this stratum neither give nor take anything from it. Let it now be carried to a superior stratum, where it takes $E + \delta E$, δE indicating the small excess of vitreous electricity which it has there taken. If we then bring it back quickly into the stratum of the electroscope, it will have $+ \delta E$ too much, and it will communicate this excess to all bodies that touch it. It will communicate it also to the electroscope if it touches it promptly, and, until the latter has lost by the contact of the air this excess which it has imparted, its leaves will diverge vitreously. On the contrary, when the insulated conductor returns from the lower region, it has $E - \delta E$ of vitreous electricity. If we make it touch the electroscope, the latter will partake of its state. Then the quantity of vitreous electricity which it will possess can no longer be in equilibrium with the influence of the mass of the surrounding air, and its natural fluid will be decomposed. But the excess of vitreous fluid which will result from this cannot cause the gold leaves to diverge, because its repulsive force will be wholly employed in compensating that of the exterior electricity E. The repulsive force, then, of the resinous electricity will alone be exerted, because nothing compensates it; and the gold leaves will diverge in virtue of this electricity, until it has been carried away and neutralized by the immediate and successive contact of the molecules of air. Experiments of this kind present the unique case of an indefinite medium, which is air, of which all the molecules are individually charged with an excess of electricity of the same kind, adhering to their surface; so that the entire mass of the medium is found penetrated with it in a proportion which varies with the altitude. Consequently the different particles of this medium can only be at rest from the mutual compensation of their repulsive

[1] M. Delarive is of opinion, not only that the evaporation thus occasioned must be very feeble, considering that the air is charged and almost always saturated with humidity; but that if it did take place, it could not generate electricity, as M. Pouillet has shown that the conversion of pure water into vapour produces no electricity. He is disposed to seek for the cause of the negative electricity of rain either in the mechanical action of the air on the falling drops, or in the sudden change of temperature which they experience.

Phenomena and Laws.

forces combined with their gravity; and the same condition is also applicable to conducting bodies which are immersed in it. Thus, for all these bodies the electrical equilibrium cannot take place when their natural electricities are completely neutralized, but only when they possess an excess of either electricity which corresponds to the stratum where they are found, an excess which is vitreous in the atmosphere when it is pure. If they possess a greater excess of this same electricity, they will act only in virtue of this excess upon each other, and upon all the molecules of the surrounding air. They ought, therefore, to repel one another mutually. If, on the contrary, the excess of electricity which they possess is less than that which they would naturally take in the stratum where we place them, the mass of the medium will act upon each of them in virtue of this difference, and their natural electricities will be decomposed as far as is necessary to supply what they want of the electricity of the medium. In virtue of this addition they will repel the medium as much as the medium repels them, and will experience no more action from it. But they will act upon each other with the excess of opposite electricity which they have acquired; and if the medium is an indefinite fluid composed of particles susceptible of electrifying itself by contact, this excess will gradually dissipate in space. Many curious experiments would be necessary to establish the laws of electrical equilibrium, under circumstances sufficiently different from those which we have been generally accustomed to consider."

Electricity of clouds. Observations of Canton;

The electricity of clouds was noticed by some of the earliest writers on the electricity of the atmosphere. Canton observed that certain clouds were charged with positive and others with negative electricity; and he noticed that the electricity indicated by his apparatus often changed five or six times in half an hour. This fact was confirmed, as we have seen, by the observations of Mr Crosse. These irregularities, however, remained unexplained till Mr Luke Howard distinctly proved that the electricity at the circumference of a nimbus is *negative*, while that of the centre is *positive;* and he suggested it as an interesting subject of inquiry to ascertain if the *negative* electricity was *descending* and the *positive ascending*. Mr J. Foggo undertook this inquiry, and in 1823 he erected a conductor armed with a smoking match, and erected from a south window. On the 12th of March 1824 there was a brisk wind from the north-west, with frequent showers all around. About three P.M. large dense clouds, which discharged heavy showers of hail, passed over the zenith. Between the showers the electricity was always positive, and the leaves of the electrometer showed their maximum divergency. So powerful indeed was the electrical state of the air, that by rubbing the outside of the glass of a detached electrometer with soft leather, the leaves opened more than forty degrees. During the showers, or when the clouds were over head, though no precipitation took place, the electricity was invariably positive, and so strong that sparks could at any time be drawn by the finger from the conducting wire. Mr Foggo likewise ascertained that by taking hold of the wire he could at pleasure intercept the electric fluid from reaching the instrument, so that the charge must have been received from the atmosphere or cloud. When the edge or the circumference of the cloud was nearly over the conductor, the electricity became negative, and appeared to be fully as strong as when it was positive. Mr Foggo, however, now found that it could not be intercepted as formerly by taking hold of the wire, or by touching it with a pointed steel rod. Hence he concluded that the electricity was not proceeding from the cloud as before, but was given off by the earth to the cloud. When the steel point was presented to the instrument, the divergence was so much increased as to endanger the gold leaf, and sparks were heard to pass rapidly between the point and the electrometer, while sharp pricks were experienced when the finger was brought near the brass cap.

of Luke Howard;

of Mr Foggo.

Observations of M. Quetelet

The subject of the electricity of clouds has been lately studied by M. Quetelet,[1] who has obtained some very interesting results. According to his observations, very great mistakes have been committed in the classification of showers of rain into positive and negative. During the same shower we may have positive or negative electricity according to the time when we make the observation. When the rain is falling, the electricity is very powerful; but if we collect it when there is an inversion of the sign, it may be nothing or next to nothing. When the air is clear, the upper strata are positively electrified in reference to the lower, the intensity increasing upwards. In order to understand what takes place when a storm cloud passes above any place, let

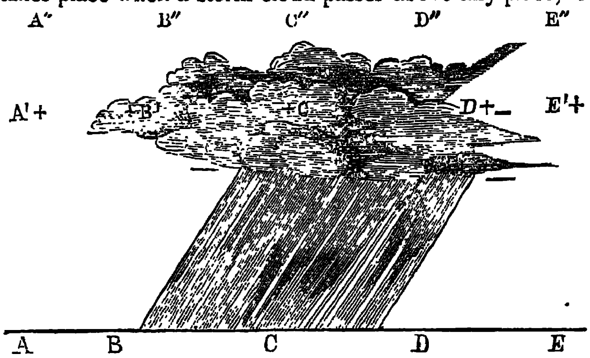

Fig. 8.

ABCDE be the ground in a neutral state, and A′B′C′D′E′ a stratum of the atmosphere positively electrified when no cloud is there; and A″ B″ C″ D″ E″ the stratum above it, also electrified positively, but in a much higher degree. If a cloud B′C′D′ arrives surcharged with positive electricity, its charge will be unequally distributed; it will be strongest in the upper part, and the cloud will be enveloped with strata of air which are relatively negative, and the more so as the electricity of the cloud is more powerful. To an observer placed at A, the electroscope above the ground will give signs of *positive* electricity. These indications will grow feebler as the cloud approaches; then the electricity disappears and becomes *negative*, which will continue even during the commencement of its passage. The electricity will then gradually diminish, then disappear, and resume its positive state when the rain commences. It will return to its first value, after having passed through the same phases, when the cloud is sufficiently distant to have no influence. The sphere of activity of a cloud is sometimes so great as to extend to several leagues. It is not uncommon to observe clouds in the horizon indicating their presence by signs of negative electricity.

M. Quetelet explains more minutely what takes place when the cloud is positively surcharged, and the rain falls. The descending shower will carry to the earth the electricity of the cloud, and with more abundance as the rain is heavy. While only a few drops have fallen, they tend only to paralyze in part the effects of the negative atmosphere which encircles the cloud, and which acts on the electrometer, which, if now observed, might lead us to believe that the rain is negative. The change of the signs of the electricity is to a certain extent gradual. In a heavy shower it is almost always instantaneous, and the passage through *zero* cannot be observed. In this state of matters all the observers below the cloud, and where it rains most strongly, ought to find the electricity positive. On the margin of the region where they are placed, the electrometer will mark *zero*, and then it will indicate negative electricity more or

[1] *Sur le Climat de la Belgique.*

Phenomena and Laws.

less powerful. The annexed figure will show by the signs + 0 − the indications of the electrometer at the surface of

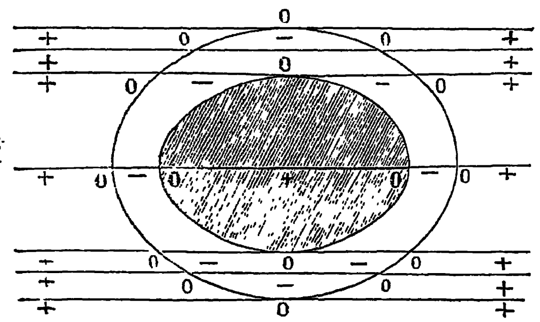

Fig. 9.

the earth on the passage of the storm cloud, or more or less in its vicinity. When the cloud is very low, so as to touch the ground, the electrometer will indicate the same electricity as that of the cloud—a fact shown in fogs, which always have an intense positive electricity; but when the cloud touches the ground it ought to lose rapidly its electricity.

When very high positive clouds give only a few drops of water, the negative atmosphere which surrounds them cannot extend its action to the earth, especially if its electricity is feeble.

When the cloud encounters mountains, it moves towards them more quickly in proportion to the negative electricity of their summits, and adheres to them like moderate conductors, abandoning successively its electricity. M. Quetelet informs us that M. Palmieri[1] has obtained similar results, with this difference, that he seems to go too far in denying the existence of clouds charged with negative electricity, and limiting the period during which positive electricity is observed to the time during which the rain falls. M. Quetelet has frequently observed the rain falling when the electrometer indicated negative electricity

Identity of electricity and lightning.

Such are the general electrical phenomena of the atmosphere during its ordinary changes; but they appear with new splendour, and at once rouse the interest of the philosopher and the dread of the vulgar, when they are exhibited in the terrific grandeur of thunder and lightning. We have already seen that various writers had pointed out the identity of lightning and the electric spark; and though Franklin has obtained the special honour of having been the first who brought down fire from heaven,

Arripuit fulmen cœlo, sceptrumque tyrannis,

yet he was no more the first who snatched the thunderbolt from heaven, than he was the first who wrested the sceptre from kings.

Observations of Franklin;

When Franklin called the attention of philosophers to the various points of resemblance between lightning and the electric spark, he conceived the idea of collecting the electricity of the atmosphere by means of pointed conductors, and of thus preserving buildings from its explosions.

of Dalibard;

One of the first philosophers who endeavoured to verify these views was M. Dalibard, who, at the instigation of Buffon, erected an atmospherical conductor at Marly le Ville, about six leagues from Paris. An iron rod, forty feet long, an inch in diameter, and pointed at its upper end, was erected in a garden upon three large poles, and insulated by silken strings, and a stool with glass feet. In M. Dalibard's absence a thunder-storm appeared on the 10th May 1752, between two and three P.M., and M. Coiffier, who had the charge of the apparatus, drew sparks with a crackling noise from the lower end of it. Having called M. Raulet, the curate of the parish, this gentleman continued for some time, and in the presence of many of his parishioners, to draw large sparks of bluish fire from the conductor. A few days afterwards, on the 18th May, M. Delors drew similar sparks from a rod ninety-nine feet high, erected in Paris. The strongest of them were drawn at the distance of nine lines, and the conductor afforded sparks even when the cloud had moved at least two leagues from above the place of observation. On the 19th day Buffon obtained, at Montbar, similar evidence of the identity of electricity and lightning.

of M. Romas.

In our history of electricity we have already given an account of the observations made with the apparatus by which Franklin, in the month of June 1752, obtained sparks of electricity from the atmosphere during a thunder-storm. Attempts were everywhere made to repeat this remarkable observation; and the most successful of these was that of M. Romas, who, according to a decision of the Academy of Sciences, had invented the electrical kite more than a year before it was employed by Dr Franklin.

His electrical kite.

The kite constructed by M. Romas was seven feet five inches high, three feet in its greatest width, and with a surface of eighteen square feet. The string was a cord wrapped round with copper wire. On the 7th June 1753 this kite was elevated to the height of 550 feet, by means of a string 700 feet long, and inclined 45° nearly. A silk cord three feet and a half long was fixed to its extremity, and suspended a large stone to govern the motion of the kite. A tube of white iron, about a foot long and an inch in diameter, was placed near the junction of the string and the silk cord, as a conductor, from which the sparks were to be drawn. From this conductor the spectators drew sparks with their fingers, keys, canes, and swords; and M. Romas having presented his knuckle, received a shock which struck him in the elbows, shoulders, breast, knees, and ankles. Seven or eight persons joined hands, and the shock struck the feet even of the fifth person. The storm now increased, and black clouds gathered in the zenith. At the distance of six inches sparks two inches long were obtained by a discharging rod. The electricity continuing to increase, flashes of fire about a foot long, three inches wide, and three lines in diameter, were frequently received, and the noise of them was audible at the distance of 500 feet. At this time he felt the sensation of a spider's web on his face when he was five feet from the string. The kite was now 650 feet high, and the wind blowing strong from the east, when M. Romas saw on the ground, about three feet from the white-iron tube, three straws dancing up and down below it. One straw was twelve, another five, and the third four inches long. The electricity having increased still more, the longest straw was attracted by the tube, accompanied with three loud sounds, which some compared to the crack of a postilion's whip, and others to that of a large pot of earthenware dashed in pieces on a pavement. This crash was heard even in the centre of the town, and the accompanying flash had the form of a spindle eight inches long and four or five lines in diameter. The long straw followed the string of the kite, and was seen moving with great rapidity even at the distance of ninety or a hundred yards, now attracted and now repelled by the string, each attraction being attended with long plates of fire and constant explosions. A phosphoric smell was distinctly felt. A permanent cylinder of light, about three or four inches in diameter, surrounded the string.

M. Romas again raised his kite on the 16th August, and though the storm was not severe, yet in an hour he obtained thirty beams of fire, nine at ten feet long, and about an inch thick, each accompanied by a noise like that of a pistol. When the glass of his discharging-rod was two feet long, he was able to conduct beams of fire six or seven feet long as easily as he had done those of seven or eight

[1] *Elettricita Atmosferica, continuazione degli studi meteorologici fatti sul real Osservatorio Vesuviano*, 4to, 1854.

Phenomena and Laws.

inches, without feeling the slightest shock. On this occasion the string of the kite was above a thousand feet long, and the metallic wire which was coiled round it was continuous throughout.

Cause of the rolling of thunder

It is obvious, from the preceding facts, that the well-known phenomenon of thunder and lightning is entirely an electrical one, the lightning being the electric spark, and the thunder the sound which accompanies it prolonged by successive echoes from among the clouds. That the clouds are capable of reflecting sound was determined by direct observation on the sound of cannon, made by Messrs Arago, Matthieu, and Prony. They observed that in a perfectly serene sky the explosions of their guns were always single and sharp, whereas when the sky was overcast, or when a cloud came in sight and covered any considerable portion of the horizon, the sound of the gun was attended by a long-continued roll like thunder; and sometimes a double sound was heard from a single shot. Sir John Herschel, however, has pointed out another cause for the rolling of thunder, as well as for its sudden and capricious bursts and variations of intensity. "To understand this cause," says he, "we must premise that, *cæteris paribus*, the estimated intensity of a sound will be proportional to the quantity of it (if we may so express ourselves) which reaches the ear in a given time. Two blows, equally loud, at precisely the same distance from the ear, will sound as one of double the intensity; an hundred struck in an instant of time will sound as one blow a hundred times more intense than if they followed in such slow succession that the ear could appreciate them singly."

Now let us conceive two equal flashes of lightning, each four miles long. both beginning at points equidistant from the auditor, but the one running out in a straight line directly away from him, the other describing an arc of a circle having him in its centre. Since the velocity of electricity is incomparably greater than that of sound, the thunder may be regarded as *originating* at one and the same instant in every point of the course of either flash. But it will reach the ear under very different circumstances in the two cases. In that of the circular flash, the sound from every point will arrive at the same instant, and affect the ear as a single explosion of stunning loudness. In that of the rectilinear flash, on the other hand, the sound from the nearest point will arrive sooner than from those at a greater distance; and those from different points will arrive in succession, occupying altogether a time equal to that required by sound to run over four miles, or about twenty seconds. Thus the same *amount* of sound is in the latter case distributed uniformly over twenty seconds of time, which in the former arrives at a single burst; of course it will have the effect of a long roar, diminishing in intensity as it comes from a greater and greater distance. If the flash be inclined in direction, the sound will reach the ear *more compactly* (i. e. in shorter time from its commencement), and proportionally more intense. If (as is almost always the case) the flash be zigzag, and composed of broken rectilinear and curvilinear portions, some concave, some convex to the ear; and if, especially, the principal trunk separates into many branches, each breaking its own way through the air, and each becoming a separate source of thunder, all the varieties of that awful sound are easily accounted for.

Distance of thunder.

The distance of the point in the atmosphere where the lightning is generated, may be readily computed by multiplying 1090 by the number of seconds which elapse between the flash and the first stroke of thunder. The product will give in feet the distance required.

The general phenomenon of thunder and lightning occurs during the passage of electricity between two clouds oppositely electrified, or one of which has an inferior charge of the same kind of electricity; but it appears in its most appalling form when the accumulated electricity of the clouds descends to the earth, shivering the strongest oak in its passage, rending the thickest walls, setting fire to houses, or stacks, or forests, and instantly destroying animal life, when the frail tenement of man or of beast happens to obstruct its path, or afford to it a more easy transit. Sometimes, however, the thunderbolt passes from the earth to the clouds, and in this case it is called the *ascending thunderbolt*. The Marquis Maffei was the first who observed this curious phenomenon. He distinctly saw during a storm the lightning issue from the ground with a loud noise. The Abbe Lioni and M. Seguier of Nismes saw the lightning rise in the form of a flame six feet high, followed by a loud noise.

Ascending thunderbolt.

One of the most interesting cases of the ascending bolt has been recorded by John Williams, Esq. It took place upon the hills above the village of Great Malvern, on the 1st of July 1826. A party had taken refuge from the storm in a circular building roofed with sheet iron, and one of the ladies on entering the hut expressed her alarm lest the lightning should be attracted by the iron roof. They had scarcely entered their retreat, and were about to partake of some refreshment, when a violent storm of thunder and lightning came on from the west. About forty-five minutes past two, a gentleman who stood at the eastern entrance saw a ball of fire which seemed to him moving on the surface of the ground. It instantly entered the hut, forcing him several paces forwards from the doorway. On his recovering from the shock, he found his sisters on the floor of the hut, fainting, as he imagined, from terror. Two of the ladies had died instantly; another lady, and the rest of the party, were much injured. The explosion which followed the flash of lightning was said by the inhabitants of the village to have been terrific. Mr Williams, who immediately examined the hut, found a large crack in the west side of the building, which passed upwards from near the ground to the frame of a small window, above which the iron roof was a little indented. Mr Williams conceived it to be quite clear, from the place of the fragments of stone and other appearances, that the clouds were negatively electrified during this storm.

Electrical phenomena on mountains; on Mount Breven;

Various electrical phenomena of a very interesting kind have been observed by travellers when ascending lofty mountains. In 1767, MM. Saussure, Pictet, and Jallabert, when on the top of Mount Breven, received small electric shocks at their finger ends by stretching out their arms, and a whistling noise even accompanied them. The gold button on M. Saussure's hat yielded distinct sparks. In 1814, a party of Englishmen experienced similar effects on Mount Ætna during a storm of thunder and lightning accompanied by a heavy fall of snow. One of the party felt his hair moving, and upon raising his hand to his head a buzzing sound issued from his fingers. The rest of the party experienced the same sensations, and by moving their hands and fingers they produced a variety of musical sounds, audible at the distance of forty feet. On the 27th of June 1825, Dr Hooker and a party of botanists witnessed effects like those described, during a fall of snow on Ben-Nevis when there was no thunder-storm. The snow fell very heavily for nearly two hours. Soon after it began, a hissing sound was heard everywhere around them, and continued about an hour and a half. It seemed to proceed from every point in the vicinity; and on arriving at the cairn on the summit of the mountain, they could almost determine the stones from which the electricity issued. The hair of several of the party exhibited, when touched, the usual electrical phenomena.

on Mount Ætna; on Ben-Nevis.

In India.

A very remarkable phenomenon of the same kind was observed by General Pollock, when in the command of a division of our Indian army and stationed at a fort about forty miles from the Khyber Pass, where the soil is an extended plain of sand. About the end of April 1842, when

Phenomena and Laws.

there was not a cloud in the sky, the air was so charged with electricity that the musket, with a fixed bayonet, of a European soldier on duty became so electrical as to emit a succession of sparks from the barrel when any conducting body touched it. General Pollock drew from it with his knuckle several powerful sparks. The barrel of the musket was insulated by the stock, which was made of wood from the Sipoo tree.[1]

On the transport of ponderable substances by lightning.

Before quitting the subject of lightning we must submit to our readers a brief account of the remarkable observations made by M. Fusinieri on the ponderable substances transported by lightning, and which it deposits in a permanent state on the bodies which obstruct its passage. When we consider the magnitude of the scale on which the great electrical machine of our atmosphere enables us to study its effects, it appears strange that so little attention has been paid to those interesting phenomena which accompany the electric stroke. M. Fusinieri is the only person who has made this an object of special investigation; and the results to which he has been led possess, as might have been expected, a very peculiar interest. The following are the general results which he obtained: Lightning contains, like the common electric spark, matter in a state of extreme division, and in a state of ignition and combustion. In the matter deposited by lightning on houses and on trees which have been struck by it, he has found *iron*, *sulphur*, and *carbon*. Lightning divides and subdivides itself indefinitely into sparks, which end in being not much larger than those of ordinary machines; and each of these sparks contains ponderable substances in the state of extreme division already mentioned. The lightning deposits the substances with which it is charged while it passes through them, and while it breaks hard bodies; and it deposits them on the surface by which it enters the body, as well as on that by which it escapes, and also on the surfaces of fracture. When the resistance to its passage is not great, it leaves no perceptible deposit; and the quantity of matter deposited increases, and is proportional to the difficulty with which the lightning traverses the body. At the same time that lightning deposits the matter which it contains, it takes up new matter from the combustible bodies, such as iron, charcoal, &c., through which it passes. The deposited matter tends always to expand itself in thin films on the surface which receives it, and it does this most readily on surfaces that are smooth and free from all asperities.

Experiments of Fusinieri.

In examining the traces left by lightning when it fell at Vicenza in 1829, and at Padua in 1831, M. Fusinieri made the following observations: It deposited, on the surface of a wall by which it entered the house, a thin layer of pulverulent matter, of a brown colour at its centre, and yellowish and much less deep at its margin. When this matter was collected and carefully examined, it proved to be *iron* in different degrees of oxidation. Upon some stones which the lightning had detached from the wall there was found a stratum the fiftieth of an inch thick, and of a brownish colour, which seemed to have undergone a species of fusion. This stratum was *sulphuret of iron*, which gradually changed into a sulphate of the same metal. M. Fusinieri indeed had previously found small crystals of sulphuret of iron upon an iron rod which the lightning had struck, and also upon a stone to which it had passed from the iron. The position of these crystals indicated that they had been formed in the middle of the passage of the lightning; a fact which he considered as proving that the electric matter could transport sulphur across metal itself. When the lightning escaped from the wall, it deposited upon the wood a dust composed of small aggregated grains, which had all the qualities of ferruginous matter. In pursuing the passage of the lightning, it was found to have divided itself into a great number of sparks more or less voluminous upon the windows, formed of pieces of rectangular glass united in a leaden frame. The traces left on the glass and on the lead were very slight, and there were only a few marks on the glass very near its contact with the lead. The traces on the lead were small cavities, round which there had been a fusion of the metal. Some of these cavities passed through the whole thickness of the lead, and their diameters varied with the size of the sparks that had produced them. In general, each cavity of any size was surrounded with several smaller cavities, which seemed to prove that each discharge was accompanied by smaller electric sparks disseminated around it. Besides these cavities, the lightning had spread on the surface of the metal a stratum of pulverulent matter, which adhered so strongly to the lead that none of it could be detached without removing at the same time a portion of the metal. Each large cavity was the centre of one of these strata, which appeared to be composed of globules of lead in the central part, and ferruginous dust on the margin. The glass, though an insulating body, was, as we have mentioned, marked also by the lightning. The origin of the thin strata formed on its surface was at those points where it had been in contact with the lead; but they extended much beyond this, and were composed at first of a powdery matter, sometimes blackish and sometimes whitish; and beyond this they terminated in continuous and diaphanous laminæ, which reflected the colours of thin plates. The central and pulverulent portion was lead; the exterior portion, and the thinnest, appeared to be iron more or less oxidated. On one occasion one of these thin plates was formed of an extremely thin stratum of metallic iron not oxidated. M. Fusinieri had formerly succeeded in diffusing metals in thin plates upon mercury by the common electric spark; and he considers the fact, that the same phenomenon takes place on glass as on mercury, as demonstrating that the effect is not owing to a molecular attraction of the surfaces, but solely by the property of expansion which is possessed in a state of fusion by those substances which are transported by the lightning. This property belongs in an especial manner to combustible bodies, particularly to metals, though these last do not all enjoy it in the same degree. Iron, for example, is more expansible than lead, as is demonstrated by the thin films which are deposited by electrical discharges.

M. Fusinieri next proceeds to describe the traces of iron, &c., which lightning deposits upon trees. By means of chemical re-agents and the magnetic needle he had previously determined that traces of iron had been left by lightning on two poplars and a pear-tree which it had struck; and he also found traces of sulphur at the extremity of the roots of a poplar tree, at which the lightning had escaped. These observations were confirmed subsequently by many others. A poplar having been struck at Casale, near Vicenza, on the 14th May 1829, M. Fusinieri found that the part of the trunk deprived of its bark was covered with small black spots, which he regarded as produced by the sparks already mentioned which had been disseminated by the electric current at the instant its bark was carried away. The bark itself must have been reduced into extremely small parts, and immediately consumed, for not a vestige of it could be found. It would appear also that the lightning had carried away a part of the wood which it decomposed, such as the carbon, while the rest was volatilized. Traces of sulphur were found at the foot of the tree; and the lightning having insinuated itself between the bark and alburnum of the roots, there was felt, by removing the former, a strong odour of sulphuretted hydrogen, similar to, though more powerful than, that which the traces of sulphur had left upon the ground. The roots torn asunder by the lightning were impregnated with a

[1] Sir W. Snow Harris's *Rudimentary Electricity*, p. 177, 3d edit., Lond. 1853.

Phenomena and Laws.

moist and brownish matter, which was extraneous, but which had penetrated into their organic tissue with the lightning which conveyed it. This matter exhaled the same fetid odour as the surrounding earth, especially that portion of the earth which, from being in contact with the roots, was impregnated with the same brownish matter. In penetrating farther into the earth, it was found traversed by serpentine furrows, covered with a cinereous matter, the odour of which was the same as that which was exhaled by the other traces of lightning. The serpentine form of these furrows clearly indicated the tendency of the lightning to disseminate itself. All these substances and deposits were carefully collected and examined by M. Fusinieri.

In a pear-tree which had been struck with lightning in 1827, M. Fusinieri discovered very remarkable effects. Though its trunk, three feet in diameter, was torn into four parts throughout its whole length, no foreign matter nor odour could be perceived either in its roots or in the earth. At the places where the branches joined the trunk, *the substance of the pear-tree* was altered to the depth of several lines. It had acquired an acid taste and a reddish colour. It exhaled while burning a penetrating and peculiar odour, and it continued to burn without flame till it was completely consumed. The matter of the lightning had therefore penetrated the tissue of the wood, and there presented traces of iron.

M. Fusinieri has collected and detailed many interesting observations respecting the substances deposited by lightning upon the various parts of houses which have been struck by it; but we regret that our limits will not permit us to pursue any farther this most important subject.

These and many other facts seem to prove that iron exists in the air and in clouds; and it is well known that the same metal mixed with manganese, nitrous salts, and organic substances, is found in rain water. M. Fusinieri is of opinion that the iron has been drawn from the earth, and chiefly from mountains, where the mines are most frequent, and where storms commonly begin to form.[1] The colouring matter of snow and rain, and the existence of meteoric stones, prove the existence in our atmosphere of dry and ferruginous vapours, the molecules of which are more or less rarefied or condensed according to the causes which may generate them. The fact that meteoric stones fall during the prevalence of storms and other electric phenomena, and especially the fact that hailstones have sometimes a nucleus of small pieces of sulphuret of iron, appear to M. Fusinieri to afford the true origin of these remarkable bodies. It has been already proved also, that electricity does transport matter; and when we consider, as Ampere has shown, that magnetic currents surround our globe, that matter in an extreme state of subdivision spontaneously expands itself, that radiating heat, like electricity, transports ponderable substances, we may obtain a very simple explanation of the origin of meteoric stones. As the temperature of the surface of the globe is not high enough to detach from it the material bodies which exist in the atmosphere, M. Fusinieri concludes that we ought to attribute this action to other causes, which are yet to be discovered, rather than deny a fact so completely demonstrated.

Effects produced by lightning.

The effects produced by lightning may be divided into mechanical, physical, and chemical. The mechanical effects of lightning are very powerful. Trees have not only been cleft and crushed to pieces, and their branches thrown to a great distance, but in some storms the sap of the tree has been drawn into steam and the dried trunk of the tree split up, as it were, into bundles of fibres like lucifer matches. When spires and elevated buildings are struck, large masses of stone are displaced or thrown down; and when houses have been injured, the articles of furniture are displaced, and even fastenings torn from the walls. M. Pouillet mentions a case, without giving the authority, where a brick wall several toises long was torn up from its foundation and carried in one piece to the distance of several toises. Effects so powerful as these are produced, as Pouillet has shown, by the sudden and simultaneous decomposition of the natural fluids of the body, which is seized with such violence that the arrangement ordinarily produced by the laws of equilibrium has not time to be effected, and the bodies are thus impelled by forces incomparably greater than those which could be resisted by the air.

Mechanical effects.

Physical effects.

The physical effects of lightning are generally limited to the production of such a degree of heat as is sufficient to set fire to the roofs of houses where there is straw or dry wood, and to the fusion of metallic bodies, such as bell wires. In some cases traces of carbonization have been found on trees struck by lightning. Effects still more powerful were observed by Dr Withering on the 3d September 1789. A man with a staff in his hand was killed when standing beneath an oak struck with lightning. The electric fluid which passed along the staff excavated a hole five inches deep and two and a half in diameter. The hole itself contained some roots of burnt grass, but upon subsequently turning up the ground it was found to be blackened to the depth of ten inches, and two inches below this the quartzy earth presented distinct traces of fusion. Among the specimens presented to the Royal Society by Dr Withering were a siliceous stone, one of the angles of which was completely fused, and a lump of sand agglutinated by the heat, in a hollow of which the siliceous matter had run, when melted, along the cavity, and formed a globular portion at the bottom.

Fulminary tubes.

By the same powerful agency are produced what are called *fulminary tubes*, which have been found in beds of sand in Cumberland, Silesia, Eastern Prussia, and near Bahia in Brazil. These tubes are in general about two inches in diameter externally, over two-tenths in their interior diameter, and about ten or twelve yards long. They are produced by the passage of the electric fluid through the sand, the particles of which are melted and agglutinated by its heat. Dr Fiegler, who has described many of these tubes from different localities, has observed that at a certain depth below these plains of sand there are little portions of water, and he ascribes the tubes as produced by the passage of the electric fluid from the surface of the ground to these portions of fluid where it is neutralized. M. Hachette conceived the idea of imitating these tubes by using a strong electrical battery; and he and M. Savart and M. Beudant having placed a quantity of pounded glass in a hole made in a brick, and having caused the electrical discharge of the battery to pass through the pounded glass, they succeeded in forming tubes exactly similar to those formed by atmospherical electricity. One of those which they made was an inch long, its external diameter varying from one-sixteenth to one-eighth of an inch, and its internal diameter being the fiftieth of an inch. In another experiment, where a little chloride of sodium was mixed with the pounded glass, the length of the tube was an inch and a fifth, and of uniform diameter. Its mean external diameter was one fifth of an inch, and its internal diameter one twentieth of an inch. When they used powder of felspar or pounded quartz, they could not succeed in making the tubes.

Produced artificially.

The repeated discharges of lightning against the summits of lofty mountains have partially fused the hard rocks of which they are composed. Saussure has observed these effects on the summit of Mont Blanc composed of schistose

[1] The returning stroke of lightning, when it passes from mountains or places containing iron and other metals, must necessarily carry along with it these substances in a state of extreme subdivision. See p. 584.

Phenomena and Laws.

amphibole, Ramond on the Pic du Midi formed of micaceous schists, and on the highest point of the volcano of Toluco MM. Humboldt and Bonpland observed more than two square inches of the rock vitrified, and in several places cavities in the interior of which there was a vitreous crust.

Vitreous mass from a hay-stack

One of the most remarkable effects of lightning which we have seen was produced in a hay-stack which was struck with lightning in the parish of Dun, near Montrose. The stack was perforated as with a red-hot bolt from top to bottom, and at the end of the perforation, where the electric fluid entered the ground, there was found a vitreous mass about the size of an infant's hand formed by the silex which exists in the hay. This specimen was in our possession for some years, and was presented to a public museum.

Disaster at Chateauneuf in 1819.

In order to give some idea of the tremendous agency of lightning, we shall give an abridged account of the disaster which befell the village of Chateauneuf-les-Moustiers, in the department of the Lower Alps, on the 11th July 1819, as communicated to the Academy of Sciences by M. Trancolye. About half-past two o'clock on Sunday, the curate of Moustiers accompanied a procession to church to instal a new rector. The weather was fine, with only a few large clouds in the sky. While a young man was chanting the epistle there was heard three claps of thunder with hardly any interval. The missal was carried away from the hands of the young man, and dashed in pieces. He himself felt as if his body was grasped tightly by the flame, which seized him by the neck. By an involuntary movement this young man, who had at first cried loudly, shut his mouth, and being thrown down was rolled upon the persons in the church, who were all thrown on the ground, and forced out at the door. Upon coming to himself again he returned to the curate, whom he found suffocated and insensible. He raised him up, put out the fire on his surplice, and restored him to life by means of vinegar about two hours after he had been stunned. The electric fluid had struck the upper part of the gold lace of his robe, ran down his arm, carried off one of his shoes to the very end of the church, broke his metallic buckle, and broke the chair on which he sat. His arms were all scarred with the lightning, and the wound did not heal for two months. A child was driven some paces from its mother's arms. Every person had their limbs paralysed. All the women were hideously dishevelled. The church was filled with a black and thick smoke, and objects were visible only by the flames of dresses set on fire by the lightning. Three persons were killed, and eighty-two wounded. The officiating priest was not struck, probably from his wearing a silk gown. All the dogs were killed on the spot where they lay. A person at a distance from the village saw three masses of fire descend upon it. The lightning first struck the cross of the spire, which was thrown to the distance of eighteen yards. An excavation of nearly two feet was made in the church, and continued under the pavement of the street, and another went beneath a stable in which five sheep and a horse were found dead.

Hail.

Among the phenomena of atmospherical electricity, one of the most interesting is the production of hailstones, particularly those of an enormous size. The connection between the formation of hail and an atmosphere highly charged with electricity has been long ago recognised; but our almost total ignorance of the subject may be inferred from the character of the hypotheses which have been framed to account for the production of hail.

Volta's theory.

Volta supposes that a small globule of snow becomes a hailstone, gradually increasing in size by being kept in a state of reciprocating motion between two clouds charged with opposite kinds of electricity, until the gravity of the constantly increasing mass overpowers the electrical force, or till the electricity of the clouds is spent by their mutual re-action.

Matteucci's theory.

M. Matteucci has justly objected to this strange hypothesis, that it is difficult to conceive how a hailstone nearly two pounds in weight could be formed by such a process. He denies that the clouds possess an electric force sufficient to produce such an effect; and, admitting that such a force does exist, he maintains that the electricity would be directly discharged from the one to the other. M. Matteucci conceives that the hailstones are produced instantaneously, and that they fall completely formed. He considers that there can be only two epochs in their formation, viz. the production of the snowy nucleus; and, secondly, that of the icy crust which covers it. When a cloud has its temperature greatly reduced, it is easy to conceive its surface covered with small flocks of snow; and if an electrical discharge should in this case pass through it, it would give rise to hail, by obliging the cooled vesicles to condense round each snowy nucleus. It is this shock, he observes, which is necessary to destroy the inertia of the particles, which ought to unite to each other, as seen in the experiment of the congelation of water with the cryophorus of Wollaston. M. Matteucci was led to these views by studying the hailstorm which took place at Tussi on the 24th July 1832. About six o'clock A.M., after a brilliant sun, the whitish and scattered clouds were seen suddenly to unite and to form a thick mass scarcely detached from the horizon, and which covered the country with a thick darkness, that continued uninterrupted by the effects of strong electrical discharges. An impetuous north-west wind soon rose, and was followed by copious rain mixed with hail. This storm, which lasted about fifteen minutes, was followed by a lucid interval, after which there fell a thick snow, which ceased and began again several times. "I do not wish," says M. Matteucci, "to cite any facts which might appear fabulous; but it appears certain that a hailstone was found which weighed *fourteen pounds*, and that another in falling upon a house forced its way through the roof; that trees from three to six centimeters in diameter were destroyed; that oxen were wounded, and that several walls were overthrown or rent by the force of the hail. I state as certain, the fact that hailstones collected a few instants after their fall still weighed a pound and a half. M. Pouillet assures us that he can himself certify that hailstones have fallen half a pound in weight. I can certify that they have fallen three times that weight."

Paragreles.

In consequence of the demonstrated connection between hailstones and a certain electrical state of our atmosphere, M. Lapostolle, professor of physics at Amiens, proposed to protect vineyards and other cultivated grounds from the destructive effects of hail, by erecting wooden poles twenty-five feet high, for the purpose of carrying off the atmospherical electricity. The use of these hailrods has extended itself over France, Switzerland, Germany, and Italy; and it is not easy to resist the evidence that has been collected of their efficacy, notwithstanding the opposition that they have met with from many scientific individuals. Each pole is supposed to protect a circle of a hundred or a hundred and thirty feet, in the centre of which they are placed. Rods of metal being too expensive, they are made of wood, in a way which will be described in a subsequent part of this article. Each rod does not cost more than a few shillings, and the practice is to take them up after having put them under cover with the other rural implements, and replace them at the vernal equinox.

Water-spouts.

Another phenomenon, which is either formed by atmospherical electricity or connected with it, is the water-spout, a meteor of rare occurrence, and often most destructive in its effects. That distinct electrical phenomena are developed during the continuance of certain water-spouts cannot be doubted; but the electricity has in these cases been supposed to be a secondary phenomenon, produced by the motion of the air. This view of the subject has received some support from the researches of M. le Comte Xavier de Maistre, who has succeeded in imitating the principal phe-

Phenomena and Laws.

nomena of water-spouts, and even the co-existing ascending and descending currents, by the mechanical circular motion of a liquid; and it is to this mechanism of the water-spout that the electrical phenomena are ascribed. The lower parts of the atmosphere, and those above the clouds are brought to the same point by the two interior and opposite currents of the spout, and strata of air charged with vapour, and often with different electricities, are thus brought into union, and produce the electrical phenomena in question.

Sheet or summer lightning.

The well-known phenomenon called *sheet or summer lightning* has recently been examined by M. Matteucci of Bologna. This ingenious author considers it to be proved that there is an accumulation of one of the two electricities at the surface of the earth; and he ascribes this electricity either to evaporation or to the analogous causes which M. Pouillet has substituted for it, or to chemical actions which are constantly going on in the interior of the earth. In order that this electricity may not escape and pass immediately into the mass of the globe, as soon as it is developed, it is necessary that the ground in which it is accumulated may not be a conductor, either from its own nature, or in consequence of the evaporation which dries it. It is also chiefly in high and insulated places rather than in the plains, above rocks rather than above forests, in summer rather than in winter, in the middle of the day rather than in the night, that these stormy clouds show themselves, whose formation cannot be well accounted for but by the influence of the electricity which the ground retains. To what other cause, he asks, can we attribute those clouds which are sometimes suddenly formed on the flanks of mountains, and afterwards rise into the air, without any variation of temperature, any change of barometrical pressure, or any other apparent modification in the state of the atmosphere? In applying these principles to the explanation of summer lightning, he considers the electricity of the earth's surface to be detained there by the desiccation of the ground, which renders it an insulator. At the moment of sunset, and during the night, the vapours which are thus condensed by cooling near the ground form a conducting stratum which serves to re-establish by degrees the electrical equilibrium between the atmosphere and the earth, which are charged with opposite electricities. It is chiefly in the plains, he conceives, that we ought to observe sheet lightning; and it ought to last a much longer time, because on elevated and insulated places the flow of electricity accumulated during the day will be much more rapid, on account of their form and position in the middle of an atmosphere more rare, more cold, and consequently more highly charged with vapours. These electrical discharges between the ground and the atmosphere may, according to our author, take place with much force, and produce even violent effects, especially if the ground and the atmosphere are too much dried; and he supposes that some earthquakes, and particularly those which take place after great droughts, may be owing to this cause. This supposition explains, in a satisfactory manner, the process employed by the ancients, and often with success, to protect from earthquakes those places which are subject to them, and which are particularly those where the nature of the ground renders the accumulation of electricity easy, and its escape difficult. This process consisted in sinking into the ground, even to a considerable depth, long bars of iron, which, according to the explanation given above, ought to facilitate the establishment of the electric equilibrium, by establishing a metallic communication between the interior of the ground and the surface, which, by its insulating faculty, retains its electricity.

Matteucci's theory of sheet lightning.

Aurora borealis.

Among the atmospheric meteors generated by electricity the aurora borealis holds a distinguished place. The phenomena which it exhibits have already been fully described under another article (the Aurora Borealis), but it belongs to our present subject to treat briefly of its electrical origin. The crackling and hissing noise of electricity passing from one place to another has been distinctly heard in this country by Mr Nairne and M. Cavallo, and we can ourselves bear testimony to the same fact. In the north of Europe the sound accompanying the northern lights is an universally admitted fact, and proves beyond a doubt that, in certain auroræ at least, the atmosphere is highly charged with electricity. Mr Trevelyan learned when he was in Faroe that the peculiar smell which accompanies electrical discharges was distinctly felt during a brilliant aurora; and in the year 1821 Sir David Brewster had the good fortune to observe, at Belleville, in Inverness-shire, an aurora, the phenomena of which were actually combined with those of a thunder-storm. This case is so remarkable, and so instructive, that we shall give the description of it in his own words: "On the evening of the 29th August, about half-past nine o'clock P.M., when there was not a breath of wind, and when the thermometer stood at 63°, the noise of very distant thunder was heard towards the south; sheets of very brilliant lightning illuminated the sky, issuing in general from a small black cloud near the horizon. I was surprised, however, to observe, that, with the exception of a few thin black clouds, which were rendered visible by the lightning, the greater part of the sky was covered with shining masses, like those which form the aurora borealis. The stars were easily seen through this luminous matter, which was arranged in irregular masses separated by clear intervals, but having a tendency to assume the appearance of irradiations diverging from the cloud whence the lightning appeared to issue. When the lightning flashed, it was propagated in a particular manner along these masses of light; but, what was very singular, the luminous patches were constantly in a tremulous or undulating motion during the intervals of the flashes of lightning. They shifted their place and changed their form exactly like the light which appears in many of the varieties of the aurora borealis. As the luminous clouds now described did not appear in the northern part of the horizon, and were distinctly related in their position and form to the thunder-cloud from which the lightning emanated, we are entitled to refer the two classes of phenomena to the peculiar electrical condition of the atmosphere, and to suppose that the phenomena of the aurora borealis may have an analogous origin. It seems now to be clearly proved that auroræ exist not only at great heights in our atmosphere, such as from 62 and 105 miles, the lowest as given by Cavendish and Dalton, to 500 and even 1000 miles, as measured by other observers: but that they appear even close to the earth, in the lowest region of the atmosphere, is clearly established by a decisive observation of Captain Parry's.[1] In the first of these cases it would be in vain to look for electrical indications, when the meteor is so far beyond the sphere of our electroscopes and the reach of hearing; but, in the latter case, we may reasonably expect not only to observe the peculiar electric state of the atmosphere, but also to hear the sound which invariably accompanies the passage of the fluid. This view of the subject reconciles the apparently contradictory observations which have been made on the aurora; and the connection of the phenomenon with the magnetic meridian, as well as its influence in certain cases on the magnetic needle, present no difficulty since the recent discoveries respecting the connection between electricity and magnetism.

Fire-balls.

That the other luminous phenomena of the atmosphere

[1] Mr W. C. Trevelyan observed that the aurora borealis in Faroe and Shetland was often seen very low, not more than 40 or 60 feet above the sea, and he learned that in both countries it is distinctly heard.

Phenomena and Laws.

have their origin in its electricity cannot be doubted. Fire-balls or globes of fire have been observed at altitudes from 30 to 100 miles, and moving with velocities varying from 5 to 33 miles in a second. These balls of light sometimes leave behind them a luminous track after they have vanished. Sometimes they explode into globes of a smaller size, sometimes they are dispersed into divided sparks, and at other times they are accompanied with showers of meteoric stones. Falling or shooting stars are only the same phenomena on a smaller scale; they appear at all seasons, but most frequently during the prevalence of the northern lights, and generally in the lower regions of the atmosphere. The prismatic columns of light which were observed by Mr Fisher and others in the arctic regions have obviously an electrical origin. "On the afternoon of the 25th October Mr Fisher observed at Winter Harbour two vertical columns of prismatic colours, about 15° on each side of the sun, which was below the horizon; they were about 5° long, and their lower end touched the horizon: they continued for about an hour, from noon to one o'clock. Similar columns were observed two or three times, and about the same time the aurora appeared.

Columns of light.

Fire of St Elmo.

The fire of St Elmo, or Castor and Pollux, is a brilliant light which frequently appears on the summits of ships' masts, on the points of bayonets, on the tops of spears, and on the tips of the ears of horses. It is obviously nothing more than the electricity discharging itself either from or into pointed bodies. Its connection with the electrical state of the atmosphere is obvious from the following account of the phenomenon as given by Lord Napier, who saw it in the Mediterranean in June 1818. "About nine, when the ship was becalmed, the darkness became intense, and was rendered still more sensible by the yellow fire that gleamed upon the horizon to the south, and associated by the deep-toned thunder which rolled at intervals in the mountains, accompanied by repeated flashes of that forked lightning whose eccentric course and dire effects set all description at defiance. By half-past nine the hands were got aloft to furl the top-gallant sails and reef the top-sails, in preparation for the threatening storm. When retiring to rest, a sudden cry of St Elme and St Ann was heard from those aloft and fore and aft the deck. On observing the appearance of the masts, the main top-gallant-mast head, from the truck, for three feet downwards, was completely enveloped in a blaze of pale phosphoric light flitting and creeping round the surface of the mast. The fore and mizen top-gallant-mast heads exhibited a similar appearance. This lambent flame preserved its intensity for the space of eight or ten minutes, and then it gradually became fainter, till it diminished at the end of half an hour."

Observed by Lord Napier.

By Count Forbin.

An interesting case of the fire of St Elmo, in which the electricity first settled on the most prominent metallic body, and then on the bodies next in conducting power, is described in the memoirs of the Count de Forbin. "In the night," says he, "it became extremely dark, and it thundered and lightened fearfully. As we were threatened with the ship being torn to pieces, I ordered the sails to be taken in. We saw from different parts of the ship above thirty St Helmo's fires; amongst the rest was one upon the top of the vane of the mainmast, *more than a foot and a half in height*. I ordered one of the sailors to take the vane down; but scarcely had he taken the vane from its place when the fire fixed itself upon the top of the mainmast, from which it was impossible to remove it."

Sometimes the electricity of the atmosphere shows itself at the yard-arms and mast-heads of vessels, in the form of balls of fire. Captain Clavering of the Griper experienced a severe gale, which lasted three days without intermission, when about 100 miles to the west of the Fiord of Drontheim. This gale was remarkable for the small amount of the effect produced on the barometer, on its approach, during its continuance, or after its cessation; and Captain Clavering was induced, from this and other causes, to ascribe it to a disturbed state of electricity in the atmosphere. It was accompanied with very vivid lightning, which is particularly unusual in high latitudes during winter, and by the frequent appearance and continuance for several minutes of balls of fire at the yard-arms and mast-heads. Of these no fewer than *eight* were counted at one time. This phenomenon is obviously an interesting variety of the fire of St Elmo.

Chemical effects.

The observations which have been detailed in the preceding section place it beyond a doubt that the electricity generated in our atmosphere is identical with that which is developed by friction. Philosophers, however, have sought to establish their similarity as chemical agents. M. Bonjol, for example, has decomposed water by means of the electricity of the air collected by an insulated pointed rod, in stormy states of the atmosphere; and the late unfortunate Mr Alexander Barry, who lost his life in the cause of science, succeeded in August 1824 in decomposing a solution of sulphate of soda coloured with syrup of violets. Bubbles of hydrogen appeared in the tube connected with the string of the electrical kite, while bubbles of oxygen appeared in the tube connected with the ground. In about ten minutes the blue liquid in the first tube became green from the separation of the soda, while the sulphuric acid, by passing to the pole in the other tube, changed its contents as usual into red. See page 597.

CHAP. III.—ON THE CHANGES PRODUCED BY ELECTRICITY ON ORGANIC AND INORGANIC BODIES.

Changes produced by electricity.

That electricity is a powerful agent in the material world, has long been the opinion of those who have studied its effects. We have clearly seen that it performs a distinguished part in the economy of our atmosphere; but there is reason to believe that its agency is still more general, and that it exercises an influence almost universal over the laws of inorganic matter, as well as over the functions of organic life. Our knowledge, however, on these subjects is but in its infancy; and though the following sections will present to the reader many interesting and important phenomena, he will not fail to deduce from them the conclusion, that a wide field of discovery is yet unexplored, and that there is no branch of science more likely to reward the diligence of the young philosopher than that which treats of the agency of the electric fluid in animal and vegetable life, its effects upon inorganic matter, and its connection with the imponderable agents of light and heat. The general effects of electrical action may be comprehended under the following heads:

1. On the mechanical changes produced by electricity on inorganic bodies.
2. On the chemical changes produced by electricity on inorganic bodies.
3. On the changes produced by electricity on phosphorescent bodies.
4. On the changes produced by electricity on odoriferous bodies.
5. On the magnetic effects of electricity.
6. On the effects of electricity on animal bodies.
7. On the effects of electricity on vegetable bodies.

SECT. I.—*On the Mechanical Changes produced by Electricity on Inorganic Bodies.*

Mechanical effects of electricity.

Although we know nothing of the real nature of the electric principle, yet, from its properties and effects, it has been found convenient to speak of it as a fluid. Its action upon bodies which either obstruct its motion, or afford it a ready passage, renders its analogy with a fluid still more

Phenomena and Laws.

striking, and we are thus enabled to comprehend phenomena which it would otherwise be more difficult to understand. A canal with a smooth bottom and sides may be considered as a good conductor of the aqueous fluid, and a river with a rocky bed and a tortuous course may be regarded as a bad conductor. Small quantities of water turned into each of these conductors will find its way by a slow movement, without injuring the surfaces over which it flows, just as a small or a large wire will carry off small quantities of electricity without suffering any mechanical change. But when the current of water is deep and strong, it will overcome its obstructions, burst its barriers, and destroy the channel which at first confined it; while the same current running with the same velocity in a smoother bed will make its way without producing any change upon the materials over which it runs; in the same manner as a small metallic wire will sometimes be expanded and sometimes burst in pieces when it transmits with difficulty an electric discharge, whereas the same discharge will find an unobstructed passage through a wire of still greater diameter.

Expansion.

The influence of electricity in expanding solid bodies was discovered by Dr Priestley during his experiments on the effects of explosion through metallic substances, when he found that a chain *was actually shortened* after the charge of a battery had been sent through it. A length of chain of exactly twenty-eight inches, after having transmitted a charge of sixty-four square feet of coated glass, was shortened one-fourth of an inch, or $\frac{1}{256}$th part of the whole.

Mr Nairne found that a piece of hard drawn iron wire, ten inches long and $\frac{1}{100}$th of an inch in diameter, after receiving many times in succession a discharge of twenty-six feet of coated glass (or nine jars), was shortened $\frac{3}{40}$ths of an inch, or $\frac{1}{133}$d of an inch, by such discharge. Its length was examined after the sixth, ninth, and fifteenth discharges. The total contraction of the wire was fully one inch and one-tenth, or *one-ninth of the whole length.*

Mr Brooke obtained a contraction still higher than this, by passing a charge of nine bottles or sixteen feet of coated surface nine times in succession through a steel wire twelve inches long and $\frac{1}{100}$th of an inch in diameter. The wire was shortened *one inch and a half*, or *one-eighth of its whole length.*

If the wire, however, through which the shock is passed has suspended to it a weight so as to stretch it considerably, the wire will be increased in length, in place of being diminished. This effect is by no means inconsistent with those already described. The heat, which, as we shall afterwards see, is always evolved during the transmission of an electric charge, produces a softness short of fluidity, which allows the extending force to overcome the absolute tenacity of the wire.

It is very obvious that the contraction of the wire in one dimension in these experiments was owing to its expansion in a direction at right angles to the length, in the same manner as a piece of caoutchouc extended in one direction is shortened in the other. Mr Nairne indeed observed that the wire had increased in thickness; but though he used a pair of scales which turned with one-eighth of a grain, he could not observe any change in the weight of the wire.

The same phenomenon takes place in fluid metals. If, for example, we fill a capillary or thermometer tube with mercury, and transmit through the mercurial column an electrical charge, the metal will suffer such a degree of expansion as to burst the tube to pieces.

When the body which transmits the shock has a less conducting power than metals, the tendency to expand will of course be still greater. If a little water, for example, is placed in a glass tube, and a shock passed through the water, the tube will burst by the expansion of the fluid; and the experiment will succeed even if a common drinking glass is filled with water and substituted for the tube.

Beccaria placed a drop of water in the centre of a solid glass-ball, and burst the ball by transmitting a shock through the fluid drop. This experiment was beautifully varied by the Italian philosopher, who constructed a small mortar, and having put a ball into it, he placed behind the ball a drop of water, so as to lie between the two wires which passed through the side of the mortar. When an electric charge was sent through the two wires, the expansion sustained by the water drove out the ball with great velocity. M. Lullin gave the ball a still greater impulsion by substituting a drop of oil for the drop of water.

Phenomena and Laws.

Even when the conductor is air, a violent expansive effect is created during the transmission of the electric shock. This effect is well shown by fitting a cork cap into an ivory mortar having a cavity an inch deep and half an inch wide. When a shock is sent through the wire in this cavity, it is expanded so suddenly as to drive out the cork with great violence.

The mechanical effect of electricity is well shown in the following experiment:—Upon the surface AB of a dry piece of wood, paste a strip of tinfoil about 18 inches long and

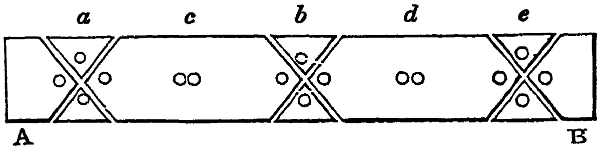

Fig. 10.

half an inch wide, and having cut out with a sharp knife small crosses at *a*, *b*, and *e*, place four wafers on each, as shown by the little circles in the figure. Place also wafers at *c* and *d*. If a strong electrical charge from a Leyden phial is passed from A to B, all the small wafers at the crosses will be violently thrown off, while those at *c* and *d* will remain in their place.

When the electric shock is made to pass through solid bodies which are imperfect conductors, such as wood, stone, sugar, and glass, they will be broken by the expansion which is produced. In the case of glass not very thick, it will be broken into innumerable pieces. When the glass is so thick as to resist the shock, it is marked with vivid prismatic colours, which Mr Henley supposes to be thin laminæ of the glass separated from one another by the shock.

The expansive effect created by the shock is finely exhibited by dipping a clean brass chain in melted rosin, and laying it upon paper. If the charge of thirty-two square feet of coated glass is sent through it, the resinous coating will be driven off from every part of the chain, which will be entirely cleared of it.

When a clean uncoated brass chain is laid upon a plate of glass, and a charge of thirty-two square feet passed through it, the glass will be marked in every part of its surface where it was touched by the chain, every marking having the width and colour of the link. The metal could be scraped off the glass at the outside of the mark, but it was actually driven in other places into the pores of the glass. Dr Priestley, who made this interesting experiment, produced a similar effect upon glass with a silver chain, and small pieces of other metals.

Diffusion of metals into vapour.

The reader who has perused with attention our chapter on Electric Light, will recognise in these experiments the origin of those beautiful results which have been obtained by Fusinieri, by passing the electric shock from a metallic ball to a polished metallic surface; and the diffusion of solid bodies into metallic vapour, as it may be called, is finely illustrated in the following experiments. Take three strips of window glass, each about three inches long and one wide, and having placed two narrow strips of gold leaf or leaf brass between them, so that the ends of the gold leaf project a little beyond the glass, transmit the charge of a large Leyden jar through the gold leaf. The gold leaf will be found to

be melted by the shock, and driven into the surface of the glass. The outer plates of glass are generally broken in this experiment, and the middle one, which frequently remains entire, has an indelible metallic stain upon each of its surfaces. This stain is obviously the metallic vapour of the gold driven into the pores of the glass.

Diffusion of metals into vapour.

The dispersion of gold or silver into a metallic vapour may be exhibited in another manner. Let a strip of gold or silver leaf, or Dutch metal, be fixed with gum to the surface of a piece of paper, and be placed in such a manner between the forceps of a universal discharger, that a strong electrical charge may be passed through it. The metallic strip will entirely disappear, in consequence of having been dispersed into a vapour or powder, part of which remains in a state of oxidation on the paper, which, from this cause, receives a greenish-brown tinge.

The metallic colours thus obtained have been employed for impressing ornamental figures upon paper or silk. In order to do this, trace the outline of the figures on thick drawing paper, and having cut it out as in stincil plates, place it on the silk or paper intended to be ornamented. When a gold leaf is laid upon it, and a card above the gold leaf, the whole is placed in a press or beneath a weight, and an electrical charge sent through it; the metallic stain is limited to the portion of the drawing paper that is cut away, and consequently any outline figure may be readily impressed upon the ground employed to receive it.

Dr Franklin was the first person who impressed metallic stains upon glass by electrical discharges. Fine gold communicated a reddish stain and silver a greenish one, and the metallic vapour, when driven into the pores of glass, was able to resist the action of the strongest aqua regia.

SECT. II.—*On the Chemical Changes produced by Electricity on Inorganic Bodies.*

Chemical changes produced by electricity.

The effects of electricity as a chemical agent are strikingly displayed in its power of evolving heat, and consequently of inflaming and fusing bodies, and its power of promoting chemical composition and decomposition. The influence of electricity in producing combustion may be shown by several beautiful experiments.

Evolution of heat.

Exp. 1. *To light a candle by Electricity.* Having wrapped some loose cotton wool round the extremity of a long brass pin or wire, roll the cotton in the powder of white or yellow rosin. Bring the naked end of the wire into contact with the external coating, while the cotton end is applied to the brass knob of a charged jar, and the rosin and cotton will be instantly inflamed.

By dipping the cotton in oil of turpentine, and using a large jar, the cotton may be inflamed in a similar manner; and its inflammation will be promoted by strewing upon it some fine brass dust.

Exp. 2. *To light a candle in another way.* Thrust a wire up through the middle of the candle to within a short distance of the wick, and having connected the outside coating of a charged jar, by means of a chain, with the lower end of the wire, touch the wick with the knob of the jar, and the candle will be lighted.

Inflammation of bodies.

Exp. 3. *To inflame Phosphorus, &c.* Having placed powdered phosphorus, rosin, or camphor, on some cotton wool, and wrapped it round one of the knobs of a discharging rod, apply the knob thus covered to the ball of a charged jar, and the naked knob to the external coating of the jar, and the powder will be set on fire.

Powdered rosin floating on water may be set on fire by transmitting a charge over the surface of the water between two points.

Exp. 4. *To inflame alcohol or ether.* The alcohol or ether being placed in an insulated metallic cup, electrify the cup, and upon taking a spark from the cup either with the knuckle or any other conductor, the fluid will be set on fire.

If ether is placed in a thin stratum upon the surface of water, in a clean wine glass, a spark taken from the surface will inflame the ether when the water is connected with the prime conductor.

Exp. 5. *To inflame gunpowder.* Upon the end of an insulated metallic wire fix a small cartridge, and when the cartridge is presented to the knob of a charged jar, the powder which it contains will be exploded.

Exp. 6. *To exhibit the heat evolved by electricity.* Take a wooden rod, for example one of red fir, about one inch thick and ten inches long, and place it between the ball of the conductor and the conducting wire; put the ball of a thermometer in a hole bored in the wood, and in a few minutes the mercury will rise to about 112°. Van Marum, who made this experiment, found that in three minutes the mercury rose from 61° to 88°, and in five minutes to 112°.

Sir William Snow Harris's thermo-electrometer for measuring the evolution of heat.

The evolution of heat by electricity is finely shown by means of a beautiful instrument constructed by Sir William Snow Harris. Mr Children and other philosophers had deduced from a variety of facts that the heat evolved by a metallic wire while transmitting an electric charge, is in some inverse ratio of its conducting power: and hence Sir William was desirous of measuring the relative degrees of heat so evolved by various metals and alloys in a gaseous medium such as air, and thus to discover their precise relations as conductors of electricity. The instrument which he used for this purpose is represented in Plate CCXXVII., fig. 1 A glass tube CDA, whose bore is regular, and somewhat less than one-tenth of an inch, has one of its extremities DA bent upwards and outwards for about two inches, and is united by welding to a spherical reservoir A, containing a coloured fluid.[1] This tube is fixed to a correctly divided scale E, supported by a suitable base; and the *zero* of the scale is at *o*, on a level with the coloured fluid in the reservoir A. Above the reservoir A is screwed air-tight, by means of brass caps closely cemented, a glass ball B, three inches in diameter; and through this ball a metallic wire *m n*, varying from $\frac{1}{100}$th to $\frac{1}{6}$th of an inch in diameter, may be passed air-tight by means of small flanges of brass *m*, *n*, fig. 2, cemented in and round two holes drilled through the ends, each flange having a small projecting shoulder to receive the wire, and, upon which are screwed two brass balls *a*, *b*, so as to render the whole air-tight. In order to fix the wire, the brass parts are made quite clean internally, and the wire being passed directly through them, is gently stretched, and then compressed in the holes by small pegs of tough wood, so as to insure a good contact. The pegs and the wire are allowed to project a little, to enable the observer to substitute different wires expeditiously. When an electrical explosion of sufficient force is now made to traverse the wire *m*, *n* in the ball B, the heat which it evolves will be made evident by the ascent of the coloured fluid along the scale E.[2]

Plate CCXXVII., figs. 1, 2.

Sir William now submitted to examination equal wires of different metals; and in order to insure the transmission of equal and similar explosions through each of them, he

[1] This fluid may consist of rectified alcohol, *one* part distilled water, *three* parts coloured tincture of cochineal, with a little sulphuric acid to make the whole sour.

[2] This instrument, which was invented by Sir Snow Harris in 1820, and described in the *Transactions of the Plymouth Institution for* 1825, has been appropriated by some foreign writers as their invention, and has been confounded by M. Fred. Ries with Kinnersley's gas thermometer, shown in Plate XXVIII. fig. 1, to which it has no relation.

Phenomena and Laws.

adopted the following contrivance. Two equal brass balls were fixed at a given distance, as in Lane's discharging electrometer. One of them, which was insulated, was placed in immediate connection with the positive side of the battery, while the other was connected with the negative side; the metallic wire to be examined forming part of the circuit. This last connection was made by means of two fixed copper wires inserted into the balls on each side of the glass, and made perfect at the points of junction. When the charge therefore of the battery was sufficiently intense to pass the given interval, the discharge took place through the wire in the ball. Sir W. Harris used a battery of *five* jars, each containing *five* square feet of coated surface. They were placed on a metallic base communicating with the negative conductor, and were charged by means of long copper rods projecting immediately from the bottom of each jar. The machine employed was a plate one, with a disc of glass three feet in diameter.

Sir W. Snow Harris's experiments on the evolution of heat by electricity.

The results which Sir William obtained from an extensive series of experiments are given in the following table.

	Metals.	Effects.
	Copper	6
	Silver	6
	Gold	9
	Zinc	18
	Platinum	30
	Iron	30
	Tin	36
	Lead	72
	Brass	18
Alloys.	Gold 1 part, copper 1 part	20
	Gold 3 parts, copper 1 part	25
	Gold 1 part, copper 3 parts	15
Alloys.	Copper 1 part, silver 1 part	6
	Copper 1 part, silver 3 parts	6
	Copper 3 parts, silver 1 part	6
Alloys.	Gold 1 part, silver 1 part	20
	Gold 1 part, silver 3 parts	15
	Gold 3 parts, silver 1 part	25
Alloys.	Tin 1 part, lead 1 part	54
	Tin 3 parts, lead 1 part	45
	Tin 1 part, lead 3 parts	63
Alloys.	Tin 1 part, zinc 1 part	27
	Tin 3 parts, zinc 1 part	32
	Copper 8 parts, tin 1 part	18

Considering the heat to be in the inverse ratio of the conducting power, it appears from this table, 1*st*, That the heats evolved from silver and copper are alike, and also those from iron and platinum, and from zinc and brass, while the heats evolved from lead and tin, from zinc and gold, and from brass and gold, are as 2 : 1. 2*dly*, That silver and copper being regarded as the *best* conductors, from being the *least* heated by the explosion, the conducting power of

Gold to copper will be as	2 :	3
Zinc or brass to copper or silver	1 :	3
Platinum or iron to copper or silver	1 :	5
Tin to copper or silver	1 :	6
Lead to copper or silver	1 :	12

3*dly*, That the conducting power of an alloy of *gold* and *copper*, or gold and silver, is less than either metal separately; and that the difference in the conducting power increases with the quantity of the inferior conductor alloyed; and that tin and lead in alloy have a conducting power equal to the mean of their two separate conducting powers. And, 4*thly*, that copper alloyed with an eighth part of its weight of tin becomes as much heated by an electrical explosion as iron.

Taking the heat of lead in the preceding table as unity, and the conducting power of the several metals named as being in a simple inverse ratio of the heat evolved; then the order and relative value of the given metals as conductors of common electricity will be as follows:

Metals.	Conducting power.	Metals.	Conducting power.
Lead	1	Zinc	4
Tin	2	Gold	8
Platinum, Iron	2·4	Copper, Silver	12

It appears from numerous experiments made with the aid of this instrument, that the heating power of the electrical discharge on metals increases as the square of the quantity of electricity discharged through them, without any relation to the intensity of the charge of the battery, as indicated by the common electroscopes or the extent of coated glass on which the given quantity is accumulated; so that the heating effect of the same quantity is always the same under the same conditions of circuit—a general law of quantity fully confirmed by Faraday in the course of his fine magneto-electrical researches. We may hence, with the data in the preceding table, easily deduce the relative quantities of electricity which the respective metals would transmit under the same elevation of temperature, and which would be nearly as follows—taking lead as unity:

Sir W. Snow Harris's experiments on the evolution of heat by electricity.

Metals.	Quantity.	Metals.	Quantity.
Lead	1	Zinc	2
Tin	1·4	Gold	2·8
Platinum, Iron	1·56	Copper, Silver	3·5

Viewing the question of conducting power in relation to the quantity of electricity which given metals can transmit under the same elevation of temperature, we should say that zinc had twice the conducting power of lead; gold twice the conducting power of tin, and so on. The relative numerical value of the metals as conductors of electricity will hence greatly depend on the particular way in which the measure of conducting power is considered. Thus it appears that the quantity which raised the temperature of lead, for example, 72° of the scale, only raised copper 6°, being in the ratio of 1 : 12. Taking these numbers as a measure of the resistance of the respective metals, and supposing the conducting power to be as the resistance inversely, then it would follow that copper has 12 times the conducting power of lead for any given quantity of electricity transmitted; it does not however follow from this, that copper can transmit 12 times the quantity of electricity under the same degree of heat,—for the resistance is found to increase with the heat evolved, and that is, with electricity of high tension such as lightning, as the square of the quantity of charge transmitted, so that it would only require about 3·5 times the quantity to raise the temperature of copper to that of lead transmitting a unit of quantity, all other things being the same.

In a further communication made to the Royal Society of Edinburgh in December 1831, the author has added considerably to our information upon this interesting question. Having adapted his instrument to the purposes of voltaic electricity, he proceeds to examine the heat excited in metallic wires by permanent electrical currents passed through them under a great variety of conditions. The following are some of the most striking of these experiments.

On exposing fine wires of different metals to electrical currents varying in intensity, he found that in certain cases the instrument ceased to be materially affected by the increased charge, the fine wire passing through the air thermometer ball not having sufficient conducting power to transmit the whole of the current, whilst in substituting wires of higher conducting power the fluid ascended the scale with great rapidity, a result identical with that arrived at by Sir H. Davy,[1] who states that in a battery where the quantity of electricity was very great and the intensity low, a foot of wire of platinum was scarcely heated whilst the same length of silver wire became red hot. It was therefore only when wires were employed of sufficient conduct-

[1] *Phil. Trans. for* 1821.

Phenomena and Laws.

ing power that we obtain indications proportionate to the increased electrical current, still no greater effect than was directly proportional to the increased power could be obtained, under any circumstances, as in the ordinary electrical discharges from the Leyden battery; a result depending probably on some peculiar condition of the species of electrical action.

In order to exemplify the effects of heat in diminishing the conduction, about six inches of the circuit transmitting the current through the instrument was made up of platinum wire of about the $\frac{1}{80}$th of an inch in diameter, and to this part of the circuit heat and cooling liquids were alternately applied; the result was that the fluid invariably descended the scale on the application of heat to the circuit wire, and ascended when that wire was cooled by evaporation, thus clearly evincing a diminished and increased power of transmission.

With a view of determining the relative conducting power of various metals, the given metal, the subject of experiment, was drawn into a wire of a given length and diameter, and caused to transmit a given current accumulation upon the wire passing through the ball of the electrometer. In order to avoid any error arising from elevation of temperature, the current wire was placed in a cool fluid medium. The facility with which the given metal transmitted the current electricity became, in this case, approximatively measured by the indications of the instrument. The order of the metals as conductors of this kind of electricity were found to be as follows:—

Silver.	Platinum.
Copper.	Lead.
Zinc.	Antimony.
Gold.	Fluid Mercury.
Tin.	Bismuth.
Iron.	

This order, with the exception of tin, is nearly the same as that already given by the ordinary electrical discharge: it was found liable to exceptions in placing the wires within the ball, as done in the preceding experiments, from the circumstances already explained—viz. that in certain cases the best conductors may appear to be the most heated.

Great care appears to have been taken in the manipulation of the experiments, and all the sources of anomaly or error liable to vitiate the result fully traced in operating upon fluid mercury, antimony, and bismuth. These metals were cast into small bars, and compared with zinc, tin, and lead, similarly heated.

Fusion of metallic wires.

Many beautiful experiments have been made by different philosophers, on the fusion of metallic wires. Mr Kinnersley, in the presence of Dr Franklin, transmitted the charge of a case of bottles through a fine iron wire. After first appearing red hot, the wire was melted into spherical drops like small shot. With a battery of thirty-two square feet, Dr Priestley melted into globules wires even so large as the seventieth of an inch in diameter, sometimes placing them in tubes of glass, and sometimes in paper. Mr Brooke, Van Marum, Baron Kienmayer, Mr Cuthbertson, and Mr Singer, made many successful experiments on the fusion of wires by electricity, and succeeded in melting them in considerable lengths; but they have given us no sufficient data for determining any of the relations of this kind of electrical action, although we find the experiments accompanied with many important and interesting observations.

Mr Singer found that the power of any coated surface to melt wires varies with the thickness of the jars; which confirms the conclusion of Mr Cavendish, that the quantity of electricity necessary to charge different jars of the same extent of coated surface is inversely as the thickness of the jars.

Mr Singer's experiments.

"The effects of gradually increasing the power of the charge," says Mr Singer, "when wires of the same length and diameter are employed, are very remarkable. If the wire be iron or steel, its colour is first changed to *yellow*, then (by an increased charge) *blue*, by a further increase it becomes *red hot*, then red hot and *fused into balls*; if we continue to increase the charge, it becomes red hot and *drops into balls*, then *disperses in a shower of balls*, and lastly disappears with a bright flash, producing an apparent smoke, which, if collected, is a very fine powder, weighing more than the metal employed, and consisting of it and a portion of the oxygen of the atmosphere, with which it has combined."

In the course of these experiments Van Marum observed the curious fact, that when a charge of 225 square feet of coated surface was transmitted through fifty feet of iron wire, *the jars were not entirely discharged*, and the residual charge was capable of melting two feet of the same wire.

The only general deductions from these experiments are by Mr Singer, who observes "that the action of electricity on wires increases in the ratio of the increased power;" because he found "that two jars charged to any degree will melt four times the length of wire melted by one jar. Mr Singer, however, found the law to vary with different jars; which would necessarily be the case so long as no quantitative measurement of the actual amount of electricity employed could be referred to. Of this, the common electrometers formerly employed show little or nothing.

With the view of determining the relative fusibility of different metals, Van Marum applied the same electrical charge to wires of different metals drawn to the same diameter. The following were the results with wires the 32d of an inch in diameter:—

Metals.	Length of Wire Fused.
Lead	120 inches.
Tin	120 ...
Iron	5 ...
Gold	3½ ...
Silver	½ ...
Brass	½ ...
Copper	½ ...

Hence he concludes that lead and tin are the worst metals for conductors, and copper, brass, and silver, the best.

Although these experiments are by no means wanting in scientific interest, they are still manifestly deficient in absolute quantitative measurement; a defect which renders them more or less indefinite and inconclusive. By means of the unit jar and other quantitative processes employed by Sir W. Snow Harris in this class of experiments, we can now determine the actual quantity of electricity in action, and estimate the relations subsisting between the indications of the intensity electrometer, and the conditions under which the charge is accumulated, whether on one or more electrical jars, or on thick glass or thin. We can estimate and measure the heating effect in relation to the quantity discharged, and determine the law of its operation, and all this in easy and intelligible terms. By means of such measurements it is now fully proved that the heating effect of a given electrical discharge is altogether independent of the indications of an intensity electrometer, and of the extent of coated glass upon which the given quantity has been collected, whether upon one, two, or more jars, or upon thick glass or thin. A given measured quantity of electricity may exhibit, under these varying conditions, all sorts and degrees of intensity, as indicated by an attractive or repulsive electrometer—such as those of Brookes and Cuthbertson; and yet at the instant of the discharge through a metallic wire the heating effect is always the same, and this heating effect is invariably as *the square of the quantity of electricity discharged* through the wire. For a given extent of coated glass taken as a constant, the quantity accumulated will be always as the square root of the attractive or repulsive force of the intensity electrometer, or commonly the indications of the intensity electrometer will be always as the square of the accumulation, all other things being

Phenomena and Laws.

the same. When the given quantity is accumulated on a greater or less extent of coated glass, these indications will be as the thickness of the glass directly and the square of the coated surface inversely—laws vital to the accuracy of experiments such as those just quoted; *e. g.*, it would not follow that in setting the slider of Cuthbertson's steelyard electrometer first at 5 grains and then at 10 grains, we should obtain quantitative accumulations in the battery in the proportion of 1 : 2. To obtain a double quantity under this kind of measurement, the slider would require to be set at 20 grains. The practical value of the ordinary intensity electroscopes and electrometers as measures of quantitative accumulation on coated glass is very small. The only certain measure of quantity, with perhaps the exception of Lane's discharging electrometer, is the unit jar. This instrument enables us to free our experiments from a complication of apparatus, which only serves to embarrass the manipulator. The accumulation being once obtained in units of quantity, we have merely to discharge our battery at pleasure by an ordinary discharger, and observe its effects on the subject of experiment.

Oxidation of metals.

Another of the chemical effects of electricity is its power of promoting the combination of metals with oxygen, or, what is the same thing, of oxidating them. Beccaria and others had observed this property of electrical action, but it is to Mr Cuthbertson and Mr Singer that we owe the most complete series of experiments on this subject. The apparatus used by Mr Cuthbertson is represented in Plate CCXXVI., fig. 5, where AB is a cylinder of glass two inches and a half in diameter and eight inches high. A brass cap is screwed on the lower brass cap B, and in the interior of the vessel is fixed a small roller CD, on which is coiled a quantity of wire attached to a pack-thread at intervals of four inches. Into the centre of the upper cap A is screwed a brass tube F, about three inches long; the end of the pack-thread and wire is pushed through it by means of a long needle, and hog's lard is placed in the tube so that the thread and wire may move through it air-tight. By this means the wire is stretched along the axis of the glass cylinder, and when one length of it is exploded, another is drawn forward by the contiguous pack-thread, without opening the cylinder. The quantity of air absorbed in the process is indicated by a gauge. It consists of a glass tube, about ten inches long, screwed into the lower end of the stop-cock, and plunged in a vessel of quicksilver, the rise of which, when the stop-cock is opened, will be a measure of the air absorbed. Mr Cuthbertson found that the air was always deprived of a portion of its oxygen. When hydrogen or nitrogen was used in place of atmospheric air, no oxidation took place in the wire, and the wire was melted and minutely divided. The results obtained by Mr Cuthbertson are given in the following table, each wire being ten inches long.

Mr Cuthbertson's apparatus. Plate CCXXVI., fig. 5.

Mr Cuthbertson's experiments.

Metals.	Diameter of wire.	Charge in Grains of Cuthbertson's Electrometer.	Colour of the Oxide when collected.
Lead............	$\frac{1}{90}$	20	Light gray.
Tin	$\frac{1}{90}$	20	Nearly white.
Zinc............	$\frac{1}{90}$	45	Nearly white.
Iron............	$\frac{1}{150}$	35	Reddish-brown.
Copper..........	$\frac{1}{150}$	35	Purple-brown.
Platina	$\frac{1}{150}$	35	Black.
Silver	$\frac{1}{150}$	40	Black.
Gold	$\frac{1}{150}$	40	Brownish-purple.

Mr Singer's experiments.

Mr Singer repeated these experiments with shorter and finer wires, and with a moderate electrical charge. The wires were not placed in receivers, but stretched parallel to the surface of a sheet of paper at the distance of one eighth of an inch. The following were his results with wires five inches long.

Metals.	Diameter of wire.	Charge in Grains of Cuthbertson's Electrometer.	Colours of the Figures on Paper.
Lead............	$\frac{1}{180}$	12	Brown and blue-gray.
Tin	$\frac{1}{180}$	11	Yellow and gray.
Zinc............	$\frac{1}{180}$	17	Dark brown.
Iron............	$\frac{1}{180}$	12	Light brown.
Copper	$\frac{1}{180}$	12	Green, yellow, & brown.
Platina.........	$\frac{1}{180}$	13	Gray and light brown.
Silver	$\frac{1}{180}$	18	Gray, brown, & green.
Gold	$\frac{1}{150}$	18	Purple and brown.

When Mr Singer made the explosion over glass, he found that a portion of the metal appeared immediately under the wire in an unoxidated state, while the oxidated portion produced round the other a figure of some width. The figures are in this way more beautiful, though less permanent, than when they are produced upon paper.

Dr Wollaston's experiments.

The oxidating power of common electricity is finely exhibited in the following experiment, given by Dr Wollaston. Having coloured a card in a strong infusion of litmus, a current of electric sparks was passed along it by means of two fine gold points, which touched the card at the distance of an inch from each other. After a very few turns of the machine, and when the card was nearly dry, a *redness* at the place of the positive wire was distinctly manifest to the naked eye; and when the experiment was repeated with the negative wire on the same spot, it was restored to its original *blue* colour.

Revival of metallic oxides.

The metallic oxides may be revived, or restored to the metallic state, by means of electricity. Beccaria, who discovered this property, revived the oxide of zinc, and produced quicksilver from cinnabar by exploding a jar between two pieces of the calces. The following method of making this interesting experiment is given by Mr Singer. Introduce into a glass tube some oxide of tin, so that the oxide may cover about half an inch of the lower internal surface of the tube when it is laid horizontally. Place the tube on the table of Henley's discharger, and introduce the pointed wires into its opposite ends, that the oxide may lie between them. When several strong charges have been sent through the tube, a part of the tube will soon be stained with metallic tin, which has been revived by the transmitted electricity. The charge of a very moderate-sized jar is sufficient to revive the mercury and sulphur which composes vermilion.

Deoxidating power of negative electricity.

The deoxidating power of negative electricity is well illustrated by the following elegant experiment of Dr Wollaston's. Having coated with wax about two or three inches of the middle of a fine silver wire, the hundred and twentieth of an inch in diameter, he cut the wire through in the middle of the wax, so as to expose a section of it. The two coated extremities of the divided wire were plunged in a solution of sulphate of copper, placed in an electric circuit between the two conductors, and sparks taken at the distance of one-tenth of an inch were passed through the solution. After a hundred turns of the machine, the wire communicating with the negative conductor had a precipitate formed upon its surface, which by burnishing was clearly copper, whereas there was no such coating upon the other wire. The direction of the electric current being reversed, the order of the phenomena was reversed, and the copper was shortly re-dissolved by the aid of the oxidating power of common electricity, and a similar precipitate formed upon the opposite wire. Dr Wollaston obtained similar results from gold wires and a solution of corrosive sublimate.

Influence of electricity in chemical composition and decomposition.

The influence of electricity in effecting chemical composition and decomposition forms one of the most interesting departments of electrical and chemical science. The most valuable researches which have been made on this subject were carried on by means of the voltaic battery, and must necessarily be detailed under another article; but the dis-

Phenomena and Laws.

coveries which were made through the agency of the electrical machine fall to be recorded in the present section.

Experiments of Mr Warltire;

One of the earliest experiments on the influence of electricity as a powerful chemical agent, was made by Mr Warltire, who fired a mixture of atmospheric air and hydrogen gas by means of electricity in a close copper vessel containing about three pints. Although no air could escape by the explosion, yet a loss of two grains was perceived in every experiment. When the vessel which contained the gases was clean and dry, a dewy moisture was found adhering to the inside of the vessel. Guided by this indication, Dr Priestley entered upon the subject. Having placed a blue solution of water and litmus in a glass tube, he transmitted through it a current of electrical sparks from a brass wire. In two or three minutes the blue liquor became red, particularly at the part where the sparks entered, and the air inclosed in the tube was diminished. The appearance of an acid having been formed at the expense of the air confined in the tube, induced Dr Priestley to place the tube in the receiver of an air-pump, so that by gradually exhausting the air, the part of it inclosed in the tube expanded and pushed out the discoloured liquor. Upon again admitting the air, a new portion of the litmus solution was introduced, while the confined air remained the same as before, and resumed the space which it had occupied after the passage of the electric current. After this the electrical sparks were no longer able to alter the colour of the solution, or to cause any decrease in the volume of the confined air.

of Dr Priestley;

In passing a current of electric sparks through olive oil, turpentine, oil of mint, and ether, Dr Priestley found that an inflammable gas was evolved.

In his experiments on the gases Dr Priestley was more successful in transmitting the spark through ammoniacal gas; he found that two hundred shocks passed through a given quantity of the gas produced an increase of volume equal to one-fourth of the whole. Upon subsequently admitting water, the original quantity operated upon was absorbed, and the remaining gas, equivalent to the expansion effected by the electric shocks, was found highly inflammable.

Dr Priestley likewise passed an electrical current, consisting of slight shocks continued for about an hour, through an inch of carbonic acid gas confined in a glass tube one-tenth of an inch in diameter, when, upon admitting the water, one-fourth part only was absorbed. In a similar manner Dr Priestley succeeded in decomposing carburetted hydrogen, the charcoal being deposited in a pulverulent form on the interior of the tube. When a succession of electric sparks from a moderate-sized conductor during the space of five minutes had failed in effecting this decomposition, he found that two shocks of a jar, each of which might be produced in less than a quarter of a minute with the same machine in the same state, were sufficient to cover the whole of the inside of the tube with the black carbonaceous matter. Dr Priestley remarked in these experiments that no shock, however powerful, would decompose the gas, if the quantity operated upon were great.

of the Hon. Mr Cavendish.

The power of electricity as a chemical agent was studied with peculiar success by the Honourable Mr Cavendish. In the year 1781 he fired 500,000 measures of hydrogen with about two and a half times that quantity of atmospheric air, and having by this means obtained a hundred and thirty-five grains of pure water, he was led to the conclusion, previously indicated by Mr Watt, that water was composed of two gases, viz., oxygen and hydrogen. In pursuing these inquiries Mr Cavendish made use of the apparatus shown in fig. 6 of Plate CCXXVI. The air to be examined was confined in a bent glass tube A, filled with mercury, and having its ends immersed each in a vessel of the same fluid. The air to be electrified was introduced by a piece of glass tube ABC, fig. 7. In order to use this apparatus, the tube ABC being filled with mercury, is introduced as in fig. 7, with its bent extremity uppermost, into the vessel containing the gas, and standing in the pneumatic trough. In this part of the process the orifice at C is stopped by a finger, by withdrawing which a little mercury will descend through C, and an equal volume of the gas will enter at the end A. When the gas has been admitted in sufficient quantity into the tube ABC, it is withdrawn and reversed, the end C, which is placed uppermost, remaining carefully closed. The extremity A, which fits the end of the tube in fig. 6, is introduced beneath the mercury in either of the glasses, and by withdrawing the finger from the upper end C of the transferring tube, the mercury will descend, and the gas will be forced into the tube A, fig. 6. The orifice of the transferring tube should not be greater than that of a common thermometer tube.

Plate CCXXVI., fig. 6.

Fig. 7.

Experiments of Mr Cavendish.

In order to introduce portions of air successively during the same experiment, Mr Cavendish used a tube AB of a small bore (see fig. 8), a bulb C, and a tube DE, having a bore larger than that of AB. This apparatus having been first filled with mercury, the bulb C and tube AB are filled with the gas, by introducing the end A beneath the inverted jar, upon the shelf of the pneumatic trough, and then drawing the mercury from the leg D by means of a syphon. The aperture A being closed, the apparatus is weighed. The extremity A, fig. 8, is then fitted into the end of the tube A, fig. 6. When it is required to force air out of this apparatus into the tube, a wooden cylinder with a tight fitting is thrust down into the tube ED, an additional quantity of mercury being occasionally poured in at E to supply the place of what is forced into the bulb C. When the experiment is completed the apparatus is again weighed. The increase of weight is due to the mercury introduced, and its volume is equal to that of the air transferred to the tube A, fig. 6. The bore of the tube A was generally one-tenth of an inch in diameter, and the aerial column in the bend of the tube from one-half to three-fourths of an inch.

Fig. 8.

In transmitting the electric spark through this tube, Mr Cavendish, instead of making one end of it communicate with a conductor, placed an insulated ball at such a distance from the conductor as to receive a spark from it, and made a communication between that ball and the mercury in one of the glasses, the mercury in the other glass communicating freely with the ground.

In transmitting the electric spark through common air in contact with a blue aqueous solution of litmus, a red tint was produced in the solution. When lime-water was inclosed in the tube instead of litmus, and sparks transmitted till there was no further diminution in the volume of the included air, no cloudiness appeared in the lime-water, and the diminution of volume, amounting to one-third of the original bulk of the air, exceeded the diminution from deoxidation alone, which would have been only one-fifth.

When this experiment was repeated with some impure oxygen gas, a considerable diminution of volume was produced, but there was no cloudiness in the lime-water, and none could be perceived by adding to it a little carbonic acid gas; a small portion of caustic ammonia, however, produced a brown precipitate. Hence it is obvious that the lime-water was saturated with some acid formed in the process.

Having inclosed in the tube some of the same impure oxygen in contact with soap leys, the diminution of volume proceeded faster than with the lime-water, the greater strength of the alkaline lixivium acting as a more powerful absorbent of the acid which was generated.

When pure oxygen or pure azote was used, no absorption took place; but when five volumes of pure oxygen were mixed with three of common air, the absorption was almost total; and as common air contains about one part of oxygen and four of azote, the mixture of five parts of oxygen and three of common air was equivalent to seven parts of oxygen and three of azote.

Mr Cavendish now supplied the interior of the tube with

Phenomena and Laws.

a little alkaline ley, and having introduced a mixture of seven parts of oxygen and three of azote, he transmitted a current of electric sparks, admitting fresh gas as the volume of air diminished. When the diminution ceased, a little pure oxygen, and afterwards a little common air, were added, in order to see if the absorption ceased from any want of a proper proportion in the two elements. As this was not the case, the soap leys were separated from the mercury, and were found to have become perfectly neutral, from their having no effect on the colour of litmus. When the leys were evaporated a dry *nitrate of potash* was obtained. By repeating this experiment on a more extended scale, Mr Cavendish demonstrated that the soap leys had been converted into a solution of nitre, and therefore established the great truth that nitric acid had been formed during the process, and that nitric acid is a compound of oxygen and azote.

Nitric acid formed.

Apparatus and experiments of Van Marum, and others.

By means of the great Teylerian electrical machine at Haerlem, Van Marum, Van Troostwyk, &c., made many experiments on the chemical agency of electricity. The apparatus which they used, shown in Plate XXIV. fig. 9, consists of a tube of glass DE, twelve inches long and a quarter of an inch in diameter, hermetically sealed, and having a gold or platina wire D*d* an inch and a half long fixed at D. Another platina wire E*e* was carried up from the open end of the tube E to *e*, within one eighth of an inch of the end *d* of the upper wire. The tube DE having been filled with distilled water, the open end of it E was immersed in a vessel V containing quicksilver, and the upper end D of the wire D*d* was brought into contact with the insulated brass ball C, placed at a little distance from AB, the prime conductor of the electrical machine. The lower wire E*e*, immersed in quicksilver, communicated with a chain VG connected with the outer coating of a Leyden jar containing about a hundred and forty-four square inches of coated glass, and having its ball M in contact with the prime conductor AB. When the electrical discharges were sent through the distilled water, the gas was disengaged as long as the ball C was in contact with the conductor; but upon increasing its distance, a position was found where the gas was disengaged, and ascended to the top of the tube. The evolution of the gas continued till it reached nearly the lower extremity of the upper wire, and then a discharge caused the whole gas to disappear, its place being supplied by water. With this apparatus the Dutch philosophers made the following experiments.

Oxygen gas from red precipitate had its original volume diminished one twentieth, and the properties of what remained were not changed.

Nitrous gas had its volume diminished to less than one half. There were no red fumes when it was mixed with atmospheric air, neither was there any condensation. It would not support combustion, and it lost its usual smell. A kind of powder covered the surface of the mercury, consisting of a new combination formed from the mercury.

Hydrogen gas, obtained from sulphuric acid and iron, suffered no diminution. Owing probably to some admixture of common air, it gave a slight redness to tincture of turnsol.

Olefiant gas from sulphuric acid and alcohol had its original volume tripled, and in some degree lost its inflammability.

Sulphurous acid gas, from sulphuric acid and charcoal, had only one eighth of its volume absorbed by water. Black spots were formed on the inside of the glass receiver. It had little smell, and extinguished a candle.

Muriatic acid gas experienced a considerable diminution of volume, but the remainder was readily absorbed by water. The electric sparks would not pass through more than two inches and a quarter of this gas.

Carbonic acid gas from sulphuric acid and chalk had its volume increased a little, and was made less absorbable by water.

Ammoniacal gas had its volume at first almost doubled, and then experienced a slight diminution. It became incapable of being absorbed by water, and exploded by the contact of flame.

Fluoric acid gas experienced no perceptible change.

Atmospheric air gave a slight redness to tincture of turnsol, and at the same time became sensibly deoxygenated. The diminution of volume was $\frac{151}{600}$ths, the mean of three experiments; and of the same air not electrified $\frac{182}{600}$ths, the mean of three experiments.

The Dutch philosophers made many other experiments which we have not space to describe, and in 1789 they succeeded in repeating the experiment of Cavendish on the decomposition of water.

Dr Wollaston's experiments and apparatus.

Hitherto a powerful apparatus was deemed necessary for effecting the decomposition of water, and a succession of discharges from a coated surface was deemed indispensable. Dr Wollaston, however, considering that the decomposition must depend upon a proper proportion between the quantity of water and the decomposing force, conceived the idea of reducing the surface of communication between the air and the metal which conveyed the electricity.

"Having procured," says he, "a small wire of fine gold, and given it as fine a point as I could, I inserted it into a capillary glass tube; and after heating the tube so as to make it adhere to the point, and cover it in every part, I gradually ground it down till, with a pocket lens, I could discern that the point of the gold was exposed.

"The success of this method exceeded my expectations. I coated several wires in the same manner, and found that when sparks from the conductors before mentioned were made to pass through water by means of a point so guarded, a spark passing to the distance of one eighth of an inch would decompose water when the point exposed did not exceed one seven hundredth of an inch in diameter. With another point, which I estimated at $\frac{1}{15000}$th, a succession of sparks one twentieth of an inch in length afforded a current of small bubbles of air.

"I have since found that the same apparatus will decompose water with a wire one fortieth of an inch diameter, coated in the manner before described, if the spark from the prime conductor passes to the distance of four tenths of an inch of air.

"In order to try how far the strength of the electric spark might be reduced by proportional diminution of the extremity of the wire, I passed a solution of gold through a capillary tube, and, by heating the tube, expelled the acid. There remained a thin film of gold lining the inner surface of the tube, which, by melting the tube, was converted into a very fine thread of gold through the substance of the glass.

"When the extremity of this thread was made the medium of communication through water, I found that the mere current of electricity would occasion a stream of very small bubbles to rise from the extremity of the gold, although the wire by which it communicated with the positive or negative conductor was placed in absolute contact with them. Hence it appears that decomposition of water may take place by common electricity as well as by the electric pile, although no discernible sparks are produced. The appearance of two currents of air may also be imitated, by occasioning the electricity to pass by fine points of communication on both sides of the water; but in fact the resemblance is not complete, for in every way in which I have tried it, I observed that each wire gave both oxygen and hydrogen gas, instead of their being formed separately, as by the electric pile.

"I am inclined to attribute the difference in this respect to the greater intensity with which it is necessary to employ

Phenomena and Laws.

common electricity; for, that positive and negative electricity so created have each the same chemical power as they are observed to have in the electric pile, may be ascertained by other means."

Dr Wollaston's experiments and apparatus.

Observations of Dr Faraday.

The preceding experiment, which is only an elegant repetition of one formerly made by Dr Pearson and the Dutch philosophers, has excited much attention, and cannot be regarded as any proof of the identity of ordinary and voltaic electricity; Dr Faraday justly remarks that it should never be quoted as establishing true electro-chemical decomposition, because the law which regulates the transference and final place of the evolved bodies has no influence here. The water is decomposed at the two poles by an independent action, and the oxygen and hydrogen evolved are the elements of the water existing at the wires the instant before. The substitution of the finger for one of the points will not interfere with the action of the other. But although Dr Wollaston did not decompose water in any way analogous to that of the pile, yet Dr Faraday seems to have succeeded in doing it by the same apparatus; but when he considered that he had obtained the true effect, the gas evolved was so small in quantity that he could not ascertain whether or not oxygen was emitted at the one wire and hydrogen at the other, as ought to have been the case.

Dr Faraday's apparatus and experiments.

The inability of Dr Wollaston's apparatus to exhibit in an unquestionable manner true electro-chemical decomposition being thus obvious, Dr Faraday devised the following ingenious arrangement for effecting chemical decomposition by ordinary electricity, and by means of it he effected true electro-chemical decompositions, perfectly identical with those produced by voltaic electricity. The plate machine which he used had its glass disc fifty inches in diameter. It had two sets of rubbers. The prime conductor consisted of two brass cylinders, connected by a third, the whole length being twelve feet, and the surface in contact with air was 1422 inches. When well excited, one revolution of the plate gives ten or twelve sparks, each an inch long; and sparks or flashes from ten to fourteen inches long may easily be drawn from the conductors. When moderately worked, each turn of the machine is made in four fifths of a second. The electric battery consists of fifteen equal jars, each twenty-three inches in circumference, and coated eight inches upward from the bottom, so as to contain 184 inches of glass each, coated on both sides, independent of the bottoms, which are thicker glass, and contain each about fifty square inches.

In order to carry off instantaneously electricity of the feeblest tension, Dr Faraday formed what he calls a *discharging train*. This discharging train consisted in connecting a sufficiently thick wire metallically, first with the metallic gas pipes of the house, then with the metal pipes of the public gas works of London, and lastly with the metallic water-pipes of London. This arrangement was so effectual that the electricity even of a single voltaic trough was instantly carried off; and this was essential to the success of many of his experiments.

Plate CCXXVII., fig. 3.

The arrangement for applying the apparatus now described to chemical decomposition is shown in Plate CCXXVII., fig. 3. Two pieces of tinfoil *a*, *b* are placed upon a glass plate raised above a piece of white paper to prevent the interference of shadows. One of these pieces *a*, is connected by an insulated wire *c*, or by a wire and wet string, with the electric machine, and the other piece *b*, by a wire *g*, with the discharging train or the negative conductor. Two pieces of fine platina wire must then be provided, bent as in fig. 4, so that the part *d* shall be nearly upright, whilst the whole rests on the three points *e*, *f*, *p*. By this means we can obtain at pleasure surfaces of contact as minute as possible; the connection can be discontinued or removed in a moment, and the substances which are acted upon can be readily examined. With this apparatus Dr Faraday obtained the following results.

Fig. 4.

1. Having made a coarse line on the glass plate with a solution of sulphate of copper, the ends *p* and *n* of the platina wires were put into it, the foil *a* being connected by a wire and wet string with the positive conductor of the machine, so that no sparks passed. After twenty turns of the machine there was so much copper precipitated on the end *p* that it looked like copper wire, no apparent change having taken place at *n*.

2. A large drop of a mixture of equal parts of muriatic acid and water coloured a deep blue by sulphate of indigo was placed on the glass, so that the ends *p* and *n* were plunged in opposite sides of it; *one* turn of the machine evolved sufficient chlorine to exhibit bleaching effects round *p*. *Twenty* revolutions produced no effect at *n*, but there was so much chlorine got free at *p*, that when the drop was stirred the whole became colourless.

3. Having mingled a solution of iodide of potassium with starch, the ends *p* and *n* were immersed in a drop of it as before; on turning the machine, iodine was evolved at *p*, but not at *n*.

Dr Faraday improved his apparatus still further by wetting a piece of filtering paper in the solution to be examined, and placing it on the glass beneath the points *p*, *n*. The paper will retain the substance evolved at the point of evolution; its whiteness will render visible the least change of colour, and will allow the point of contact between it and the wires *p*, *n* to be contracted to the utmost degree. Dr Faraday found a piece of paper moistened in the solution of iodide of potassium and starch, or of the iodide alone, to be with certain precautions a most admirable test of electro-chemical action; and when it is placed and acted upon in the manner already described, it will exhibit the evolution of iodine at *p* by half a turn only of the machine. He found, indeed, that with these adjustments, and the use of iodide of potassium on paper, chemical action is sometimes a more delicate test of electrical currents than the most delicate galvanometer.

A piece of litmus paper wetted in a solution of muriate or sulphate of soda was quickly reddened at *p*, and a similar piece wetted in muriatic acid was soon bleached at *p*, no similar effects taking place at *n*.

A piece of turmeric paper wetted in a solution of sulphate of soda was reddened at *n* by two or three turns of the machine, and by twenty or thirty turns abundance of alkali was evolved at the same place. By turning the paper round so that the spot came under *p*, and working the machine, the alkali soon disappeared, the place became yellow, and a brown alkaline spot appeared in the new part under *n*.

Dr Faraday next combined a piece of turmeric paper with a piece of litmus, wetting both with a solution of sulphate of soda. The paper was placed so that *p* was on the litmus and *n* on the turmeric paper. By a few turns of the machine, acid was evolved at *p* and alkali at *n*, as in galvanic decomposition. These various decompositions were equally effected whether the electricity passed to the foil *a* from the machine through water or wire only, by *contact* with the conductor, or by *sparks* there, provided the sparks were not so large as to cause the electricity to pass in sparks from *p* to *n*, or towards *n*.

Dr Faraday's final experiment deserves peculiar notice, as affording a case in which there is the most perfect analogy between the effects of ordinary and voltaic electricity. Three compound pieces of litmus and turmeric paper, when wetted by a solution of sulphate of soda, were disposed on a plate of glass as shown in fig. 5. The wire *m* was connected with the prime conductor, *t* with the discharging train, and the wires *r* and *s* connected the moistened pieces of paper, each wire resting on three points, one of the points, at *r* and *s*, being on the glass, and the others on the papers, the ends *p*, *p*, *p* resting on the litmus and *n*, *n*, *n* on the tur-

Plate CCXXVII., fig. 5.

Phenomena and Laws.

meric paper. When the machine had been worked for a short time, acid was evolved at all the poles *p*, *p*, *p*, by which the electricity entered the solution; and alkali at the other poles *n*, *n*, *n*, by which the electricity left the solution.

The precaution above referred to, in using the iodide of potassium as a test of electro-chemical action, is that no sparks should be passed in any part of the current, and no increase of intensity allowed by which the electricity may be induced to pass between the platina wires and the moistened papers, *otherwise than by conduction;* for if the electricity burst through the air, a different effect is produced. The litmus paper is in this case reddened by the spark, and iodine will be evolved from paper moistened by iodide of potassium. This effect is owing to the formation of nitric acid by the oxygen and nitrogen of the air. The acid thus formed reddens the litmus paper, or prevents the exhibition of alkali in the turmeric paper, or evolves iodine from the iodide of potassium. We have thus a simple and elegant method of illustrating Mr Cavendish's experiment of forming nitric acid from the atmosphere.

M. Bonjol's experiments.

M. Bonjol of Geneva was among the first who decomposed water by common electricity. The electricity was obtained from an insulated lightning rod; and the decomposition is said to have proceeded continuously and rapidly even when the electricity of the atmosphere was by no means powerful. M. Bonjol also decomposed potash and chloride of silver, by passing the sparks of an ordinary machine through these substances placed in narrow tubes. Dr Faraday justly regards these as not cases of true electro-chemical decomposition, but as analogous to that of Dr Wollaston's apparatus, arising either from a very high temperature acting upon minute portions of matter, or perhaps connected with the results produced in air by the passage of the spark.

Experiments of Dr Barry.

One of the most remarkable decompositions, however, which has been obtained previous to Dr Faraday's experiments, is that of the late Dr Barry. This experiment is given as a proof of the chemical action of atmospheric electricity; but, as Dr Faraday has shown, it possesses a much greater interest if confirmed. The following is his own account of it:—"In August 1824 I elevated the kite in an atmosphere favourable to the exhibition of its phenomena. It was raised from an apparatus firmly fixed in the earth, and was insulated by a glass pillar. The usual shocks were felt on touching the string, which simple fact I am induced to mention from the circumstance of no electrometer having been employed. The portion of string let out, with a double gilt thread passed through it, was about 500 yards. I then made the connection shown in fig. 6, where the straight glass tubes, A, B, having platina wires passed from above half down their axes, and standing in their respective glass cups C, D, were filled with a solution of sulphate of soda coloured with syrup of violets connected also with each other by the bent glass tube E, likewise filled with the above solution in the usual manner. A portion of gilt thread *d* was then brought from the tube at A, and united to the kite-string K, whilst a similar thread *b* was carried from B to the earth. Bubbles of hydrogen in A, and of oxygen in B, soon appeared. In about ten minutes the blue liquid in A became green from the separation of the soda, whilst the sulphuric acid, by passing to the pole in the tube B, changed its contents, as usual, red.[1]

Plate CCXXVII., fig. 6.

Dr Faraday's observations on them.

The effect now described as produced by *atmospheric electricity* was never produced by *common electricity*. Dr Wollaston and other philosophers could not obtain the gases in separate vessels, and Dr Faraday kept his powerful machine in action for a quarter of an hour, during which 700 revolutions were made, without producing any sensible effect, although the shocks that it could then have given must have been more numerous and powerful than could have been taken with any chance of safety from the kite-string of Mr Barry. Dr Faraday thinks "it just possible that the air which was passing by the kite and string, being in an electrical state sufficient to produce the 'usual shocks' only, could still, when the electricity was drawn off below, renew the charge, and so continue the current. The string was 1500 feet long, and contained two double threads; but when the enormous quantity which must have been thus collected is considered, the explanation seems very doubtful." Dr Faraday therefore considers Mr Barry's experiment as a very important one to repeat and verify; and he remarks, that if it is confirmed, it will be the first recorded case of the true electro-chemical decomposition of water by common electricity, and will supply a form of electrical current which is exactly intermediate, both in point of quantity and intensity, between those of the common electrical machine and the voltaic pile.

Effects of electricity on gases.

The effects of electricity on mixed and compound gases have been given by Mr Singer in his work on electricity. These effects are regarded by Mr Singer as mechanical, and as arising from the momentary agitation into which the various media are thrown by the action of the spark, which tends to promote a new arrangement of parts. This theory, of which Mr Singer himself not only saw but has stated the difficulties, cannot now be maintained with any show of reason; and there can be no doubt that the effects in question arise from a molecular polarity related to the two poles of the electric circuit, or to the two kinds of electricity which exist in nature.

Influence of electricity on putrefaction

It has been asserted, but not from any extensive series of accurate experiments, that putrefaction and fermentation are promoted by electricity. M. Achard of Berlin, considering that, in animals killed by lightning, the process of putrefaction advances with great rapidity, cut a piece of beef into three parts, and electrified one piece positively for ten hours, another negatively during the same time, while the third was not electrified at all. On the fourth day the electrified pieces had an intolerably fetid smell, while the unelectrified piece had only begun to smell a little. The same result was obtained with a piece of boiled veal. M. Achard also killed several birds by electrical shocks, and having killed others by sticking a needle through their heads, he placed them all under similar circumstances. The birds killed by electricity became putrid much sooner than the rest. The influence of electricity on fermentation was studied also by M. Achard. A handful of rye brought into a state of fermentation for the purpose of being distilled, was separated into two portions, one of which was electrified and the other not. Five hours afterwards the vinous fermentation had ceased in the electrified portion, but did not cease in the other portion till after the lapse of eight hours.

and fermentation.

Influence of electricity on colours.

The influence of electricity upon colours is a subject of peculiar interest, and cannot fail to prove a rich field of discovery to those who may enter upon it with ardour. That electricity does alter the colour of particular bodies is undoubted; but whether it produces a real chemical change on these bodies, or merely a transient change in their power of absorbing specific rays of the spectrum, remains to be determined. The few experiments made by Cavallo are extremely vague. He found that vermilion, carmine, verdigris, white and red lead, had their colour altered by the electric shock; and that the colours of orpiment, gamboge, sage-green, red ink, ultramarine, Prussian blue, and of a few other compounds, were not altered. The eye, however, is no judge of a real change of colour. It can judge only of the general result of the change, without indicating the nature of the change or changes that have taken place. A body, too, which may have lost or gained

[1] *Phil. Trans.* 1831. Part I., pp. 165, 166.

Phenomena and Laws.

the power of absorbing definite rays of the spectrum, may often appear to have suffered no change at all, provided that the sum of the changes is a colour similar to the original colour of the body.

In producing these effects, namely, putrefaction, fermentation, and change of colour, the electric fluid may act, not by any virtue of its own, but by the intermedium of those ponderable substances which the spark carries along with it, and consequently leaves in bodies.

Sect. III.—*On the Changes produced by Electricity on Phosphorescent Bodies.*

Influence of electricity on phosphorescence.

Although the phenomena of phosphorescence have been lately much studied, yet philosophers are very little acquainted with its cause, whether it is developed by the light of the sun, the action of heat, or the transmission of electricity.

Almost all bodies may be rendered luminous during the transmission of an electric discharge through their substance; but unless this luminosity continues after the discharge is over, the body cannot be said to have been rendered phosphorescent by electricity. In his numerous experiments on this subject, Mr Skrimshire invariably kept his eyes closed till the sound of the discharge had been heard, and therefore the light which he then saw was not the light of the electric spark, modified by its transmission through the body, but was a real phosphorescence, which continued after the original cause of it was withdrawn.

The substances which he submitted to examination, including minerals of all classes, were placed on a horizontal brass plate, fixed to the ball of the prime conductor, and he then tried to obtain a spark from the body by means of a common discharger. The body was next placed upon a table, and the charge of a Leyden phial passed *over it*, at the distance of about a quarter or half an inch above its surface; and, as a last trial, the charge of the jar was made to traverse its surface by resting the points of the discharging rod at an inch or more distant from each other, upon the specimens under examination.

As many bodies possess the property of becoming phosphorescent by heat, the phosphorescence produced in the preceding experiments may in general be ascribed to the heat which accompanies an electrical discharge. But although the heat thus produced may be either the sole or an auxiliary cause of the phosphorescence which is excited in bodies which are known to be phosphorescent by common heat, yet it is obvious from other experiments, that electricity exercises a specific influence upon that peculiar structure or condition of bodies which causes them to give out light when heated.

Experiments of Dessaignes.

M. Dessaignes seems to have been the first person who established a relation between electricity and phosphorescence. He found that the metallic powders, such as those of zinc and antimony, which are the most phosphorescent, lose their luminous qualities in a damp state of the atmosphere. Even in dry weather antimony loses its power of phosphorescing if it be rubbed in a metallic mortar; whereas, in an insulated mortar the light is very much increased. Glass pounded in dry weather becomes much more luminous than when it is pounded in a damp state of the air. It loses this property entirely in wet linen; but being as it were self-insulated, it is not deprived of its phosphorescence, like antimony, by being pounded in a mortar, which is a conductor of electricity. In order to make adularia phosphoresce briskly it must be pounded in an insulating or insulated mortar, and the handle of the pestle should likewise be insulated. M. Dessaignes also found that *if glass be calcined till its phosphorescence is diminished, it resumes that property by being exposed on an insulated support, and subjected to a few electrical discharges, or to a current of electrical matter.* Other substances which have *lost their phosphorescence* by calcination resume it when electrified; but our author remarked *that electricity does not restore the phosphorescence of those substances which have been deprived of it by the light of the sun.*

In pursuing this branch of the subject M. Dessaignes found that those phosphorescent substances which are imperfect conductors of electricity, are susceptible of receiving the luminous property from the action of the sun's rays; that *non-conductors* will not thus phosphoresce at all, or at least very imperfectly; and that most conductors give out no light whatever. Orpiment, and some of the oxides of arsenic, tin, zinc, and lead, are exceptions to this remark, and also the muriate of tin, and the sulphate and phosphate of lead. Non-conductors, and conductors which refuse to phosphoresce after feeble electrical discharges, become luminous after strong ones; while imperfect conductors that phosphoresce after weak electrical discharges give no light whatever when the discharges are much increased. In support of the analogy between electricity and phosphorescence, M. Dessaignes remarks that phosphorescence is affected by the presence of points. Fluor spar, which has the asperities produced by fracture, phosphoresces readily, while the entire and smooth crystal remains dark. The same is true of calcareous spar, adularia, apatite, emerald, and common salt. If both sides of the glass be rough, it phosphoresces throughout; but if one side be rough and the other polished, it only shines when the rough surface receives the heat. It is a fact still more curious, that when Iceland crystal with smooth faces is exposed to the solar rays, it acquires very little phosphorescence; whereas, if but one of the faces is roughened and exposed to the sun, it readily becomes luminous. In like manner, arragonite becomes luminous when a fractured face is exposed to the sun, but acquires very little light when the smooth natural surface is exposed to it. M. Dessaignes likewise maintains that nearly all the bodies that are susceptible of phosphorescence by friction become luminous by heat, by electricity and by exposure to light. The general view which our author takes of these phenomena is, that phosphorescence is produced by a particular fluid, which is set in motion by light, by heat, by electricity, and by friction, and that it is dissipated by overheating or too long exposure to light.

Experiments of Mr Pearsall.

The influence of electricity upon phosphorescence and the colours of certain bodies has been examined by Mr Pearsall, who has amply confirmed the general result deduced experimentally by M. Dessaignes, that bodies which have lost their phosphorescent property by calcination acquire it again when an electrical discharge is passed through them. Having submitted a piece of chlorophane to a powerful heat, it gave out a strong phosphorescent light of a *pale violet colour;* but the specimen decrepitated so much during its calcination that a piece of sufficient size to be electrified could not be preserved. He therefore placed the calcined fragments in a glass tube, and sent through them three electrical discharges, the effect of which was the emission of a *deep violet light.* He then heated the fragments upon platinum, and they emitted a phosphoric light of different colours. Some of the fragments appeared *green,* others *yellow,* and all of them finished by emitting a *deep violet light.* These colours are evidently distinct from those of the natural mineral, for a portion of the latter heated at the same time produced only a *feeble violet colour.* Another portion of the same specimen, calcined but not electrified, emitted no light when heated.

A specimen of chlorophane, whose phosphorescence had been destroyed by an intense heat, was exposed to the solar rays for two days without any of its phosphorescent quality being restored. A single electrical discharge, however, restored its phosphorescence, which increased in the ratio of the number and the intensity of the shocks it received.

Phenomena and Laws.

Experiments of Mr Pearsall.

The green light emitted by the action of heat was more deep and of longer continuance after three, six, or even twelve discharges, than after one. Mr Pearsall obtained the same results with apatite and some diamonds; but electricity produced no effect in developing phosphorescence by heat in amethyst, sapphire, ruby, garnets, and other mineral substances which he tried.

In the course of his experiments Mr Pearsall observed the curious fact, that the specimens of fluor spar, though colourless in their natural state, received a bluish tint when electrified, and the acquired phosphorescence was proportional to the depth of the tint. When a number of fragments were used, the larger fragments were of a blue colour, and emitted a blue light when heated, whereas the smaller fragments emitted only a pale yellow light. Mr Pearsall thinks it probable that the phosphorescent property is communicated by electricity only to the surface, which he considers as explaining the fact that fragments of different dimensions emit differently coloured lights.

In resuming the investigation of this subject, Mr Pearsall found, that bodies not naturally phosphorescent, such as statuary marble in its natural or calcined state, ivory when its carbonaceous part was removed, calcined mother of pearl, calcined oyster shells, calcined petuncles, egg shells, and lime, were not only rendered phosphorescent by heat after being strongly electrified, but acquired this property with a beauty, a variety, and an intensity of colour superior to those which occur in specimens that possess a natural phosphorescence. We regret that our limits will not permit us to give in detail a second series of experiments which Mr Pearsall performed with twelve different varieties of fluor spar, all of which gave distinct phosphorescence previous to their being electrified; but the general result of them may be thus expressed. When the natural spars emit by heat a light of different colours, the electric action produces only one of them; but when the mineral yields only one natural colour by heat, this is replaced, when electricity is applied, by a phosphorescence of various colours, among which the primitive tint does not appear. As the colours change with the number of electrical discharges, Mr Pearsall found the following to be the order of progression. The specimen was a green fluor.

1 discharge,		pale purple light when heated.
2	... ...	pale green, changing into purple.
3	... ...	the same colours, more intense and durable.
4	... ...	purple, with increased intensity.
6	... ...	green, brighter and deeper.
10	... ...	green bright: fine and more durable purple.
20	... ...	deep and more durable colours.
40	... ...	very rich colours, the purple at last inclining to red.
100	... ...	green colour, highly brilliant, and becoming yellowish. The purple had now a superb tint.
160	... ...	an intense light nearly white, followed with a brilliant green light, then with a durable purple, and then with a yellow accompanied with violet tints.

This specimen had been successively heated and electrified nearly fifteen times, and had suffered no deterioration in its phosphorescent property.

Mr Pearsall next shows that the property communicated by electricity was preserved even for *three* months, when the specimen was kept in the dark. Out of twelve fragments, two had completely lost their acquired phosphorescence by exposure to the sun for twenty-one days, five had nearly lost it, and six had experienced a modification in their colours by this exposure.

Mr Pearsall now examined the influence of electricity on the natural phosphorescence of bodies, and he found that an augmentation of intensity was produced, of which it is difficult to give an idea. Specimens of fluor whose pyro-phosphorescence was feeble or uncertain, were raised to the rank of highly phosphorescent bodies, and some of them even rivalled the Siberian fluor. At the end of fifty days some of these specimens still preserved the excess of phosphorescence which had been communicated to them, while others continued to exhibit the same order of colours.

Phenomena and Laws.

Experiments of Mr Pearsall.

Mr Pearsall has brought forward several experiments to prove that the phosphorescence of bodies, and the modifications it experiences, depend on their structure and mechanical condition. Phosphate of lime, for example, which in the form of *apatite* has an intense natural phosphorescence, has none when aggregated from a precipitation of it in a solution of muriatic acid, nor when obtained from powdered or calcined apatite. A calculus of phosphate of lime, however, gave green, yellow, and orange light when heated after having been calcined and exposed to twenty electrical discharges. Mr Pearsall also several times observed that the power of phosphorescence returned after it had disappeared.

With the view of showing that the phosphorescence was not owing to any radiating matter which was carried along with the sparks, Mr Pearsall inclosed coloured chlorophane in glass tubes hermetically sealed, and found them phosphorescent after 225 discharges. He found voltaic electricity capable of producing phosphorescence in some cases and not in others; so that it differs greatly from common electricity in this property.

In explaining the preceding phenomena, Mr Pearsall considers the intense electricity of the Leyden jar as altering the structure upon which phorphorescence depends, by the vibratory motion which it communicates, and which allows the particles to take a new arrangement. When the body has had a new structure communicated to it by the vibrations or shocks of each electrical discharge, the action of heat is supposed by our author to permit the body to return to its primitive structure; and he conceives that the vibrations of the atoms during these changes of structure may produce light.

Sect. IV.—*On the Changes produced by Electricity on Odoriferous Bodies.*

Influence on odoriferous bodies.

It was discovered by M. Libri of Florence that electricity exercises a curious influence over odoriferous bodies. Having caused a continued current of electricity to traverse a piece of camphor, the odour of this substance became more and more feeble, and at last entirely disappeared. When the camphor has suffered this change, and is withdrawn from all electrical influence, and put in communication with the ground, it will remain without odour for some time, but it will afterwards resume its former properties slowly and gradually. M. Libri seems to have obtained a similar result with other odoriferous bodies; but he has not, so far as we know, given any more particular account of his researches.

Sect. V.—*On the Magnetic Effects of Electricity.*

Magnetic effects of electricity

During almost every period of the history of electricity, philosophers have pointed out strong resemblances between the phenomena which it exhibits and those of magnetism. Some of the most striking points of resemblance were, that each consisted, as it were, of two powers or directions of powers, of an opposite nature, and subjected to similar laws of attraction and repulsion; that the action of magnetism has a great analogy with that of electricity; that the distribution of the forces in an electrified body differs very little from that of the forces in a magnet; and that the pyro-electrical tourmaline has the strongest resemblance to an artificial magnet.

These views were powerfully confirmed by the fact, often observed, that magnetism was communicated to bodies by a stroke of lightning, and that the compass needles of ships have had their polarity changed by a similar cause The

Phenomena and Laws.

Effects of lightning on compass needles.

ship Dover was struck by lightning in the Atlantic on the 9th January 1749; and in four compasses on board, one of which was in a brass box, and the other three in wooden boxes, *all the needles had lost their virtue.* At first their polarity seemed to have been nearly reversed, but after a little while they moved about in every direction, and were of no use. Mr Gowin Knight, having examined one of these compasses, observed that the outward case was joined together by pieces of iron wire, sixteen of which were found in the sides of the box and ten in the bottom. By applying a small needle to each of these wires, Mr Knight found that they were all strongly magnetical, particularly those which had joined the sides.

Another very remarkable case occurred on board the New York Packet, in its voyage from America to Liverpool in 1827; and as a very accurate description of it was communicated by the Rev. Mr Scoresby to the British Association at York in 1831, we shall lay before our readers his own abstract of it. "Soon after the commencement of the voyage, this vessel encountered a severe thunderstorm, and received a stroke of lightning, which shattered the masts in several parts, and started some of the exterior planks of the bends. This was in the morning before day-light. The weather continuing unsettled, and the air in a highly electric state, with water-spouts in various directions around, the captain, fearing another explosion from the highly charged atmosphere, put up a lightning conductor which he had on board. In the afternoon of the same day the ship was a second time struck, but preserved by the conductor, though the iron of which it was composed was destroyed, and fell in melted globules upon the deck. No lives were lost, though some of the crew received heavy shocks; whilst one person, an invalid passenger, derived essential benefit from the electric discharge. Mr Scoresby had an opportunity of examining the vessel immediately on her arrival in Liverpool, when, on investigating the condition of the iron on board, he found almost every article capable of permanent magnetism, with sensible polarity. Table-knives and forks were capable of lifting needles or small nails, and one knife sustained a travelling-trunk key. Most of the watches on board suffered by the magnetic influence, especially those which were under the pillows of their owners in bed. These were all stopped, and on examination were found so highly magnetic that portions of the steel-work were capable of suspension by each other, in a chain of three or four pieces. Of one of these pieces (the cap-spring) Mr Scoresby made a pocket compass, which was exhibited when his communication to the association was made, and was observed to be in all respects a delicate and perfect instrument."

Experiments of Franklin.

In enumerating the points of analogy between lightning and electricity, Dr Franklin remarks that they have both the power, not merely of reversing the poles of magnets, but of completely destroying their magnetism. By discharging four large jars through a common sewing needle, he communicated to it such a degree of magnetism, that it placed itself on the plane of the magnetic meridian when it was made to float on water. If at the time of receiving the discharge the needle lay east and west, the end at which the discharge entered pointed north; but if the needle lay north and south, the end which lay to the north continued to point to the north, at whatever end the discharge entered. He found also that the magnetic intensity developed in a needle was a *maximum* when the needle lay north and south, and a *minimum* when it lay east and west, at the time of receiving the electrical discharge. If the charge of a large jar or battery is transmitted through a steel wire perpendicular to the horizon, it will be permanently magnetized, and the lower end, at the time of the discharge, will afterwards turn to the north when it is made to traverse in a horizontal plane. If we now replace the wire in its vertical position, the end which was formerly the lowest being now the highest, and again transmit the discharge, the polarity of the needle will either be completely destroyed, or the poles will be reversed.

It has been found also that the polarity of a natural magnet may be completely destroyed by transmitting through it the charge of a battery.

Experiments of Beccaria;

In repeating the experiments of Franklin, Beccaria discovered that lightning always communicates the magnetic polarity to bodies containing iron, and he observed this phenomenon even in common bricks that had been struck by lightning. Guided by the observations which he made on the polarity of such bodies, he was able to trace the directions which the lightning had taken in passing through them.

of Van Marum.

A series of elaborate experiments were made by Van Marum, on the magnetic effects of electricity. He employed a battery of 135 jars, containing 130 square feet of coated surface, and he transmitted the powerful charges which it yielded through watch-spring needles from three to six inches long, and also through steel bars nine inches long, between a quarter and half an inch broad, and nearly a line thick.

In this way he found that when the needle or bar was placed horizontally in the plane of the magnetic meridian, its north end acquired north polarity, and its south end south polarity, in whatever direction it received the discharge. When the bars possessed some degree of polarity before receiving the shock, it was either diminished or reversed after receiving it. When the needle or bar received the shock in a vertical position, its lower end became the north pole whether it had been previously magnetic or not. Generally speaking, the degree of magnetism which was communicated was as strong in a horizontal as in a vertical position. When the needle was placed in the magnetic equator, and received the discharge longitudinally or along its axis, it received no magnetism whatever; but when the *shock was passed through its width, or at right angles to its axis,* the needle received a considerable degree of magnetism, the end which pointed to the west becoming the north pole, and that which pointed to the east the south pole.

When the charge was so powerful as to render the needle hot, no sensible polarity was communicated to it.

Discovery of electro-magnetism by Professor Oersted.

Such was the state of our knowledge respecting the connection between electricity and magnetism, when Professor Oersted of Copenhagen, led by theoretical views, established a most interesting relation between these two powers, and laid the foundation of the new science of *Electro-magnetism*, or *Magneto-electricity*. The fundamental fact which Mr Oersted discovered may be thus expressed.

When a wire conducting electricity is placed parallel to a magnetic needle properly suspended, the needle will deviate from its original or natural direction. This deviation follows a regular law.

1. If the needle is *above* the conducting wire, and the positive electricity goes from right to left, the *north* end of the needle will be moved *from* the observer.

2. If the needle is *below* the wire, and the positive electricity passes as before, the *north* end of the needle will be moved *towards* the observer.

3. If the needle is in the same horizontal plane with the wire, and is between the observer and the wire, the *north* end of it will be *elevated.*

4. If the needle is similarly placed on the opposite side, the *north* end of it will be depressed. In these two experiments the needle must be very near the wire.

From these simple facts Mr Oersted concludes, *that the magnetical action of the electrical current has a circular motion round the wire which conducts it.* This law will be understood by inspecting Plate CCXXVI., fig. 10, where, if

Phenomena and Laws.

AB is the conducting wire or the direction of the positive electricity, the circle *c d e f* will be the plane in which the magnetical circulation takes place. The small arrows show the direction of the austral or polar magnetism, the sharp ends or heads of the arrows indicating the direction in which the *austral* magnetism, and consequently the *north end* of the needle is *repelled*, and the *boreal* or north-polar magnetism is attracted; while the opposite ends of the arrows indicate the direction in which the *boreal* magnetism, and consequently the *south end* of the needle is *repelled*, and the opposite magnetism attracted.

Dr Colladon's experiments with ordinary electricity.

The preceding discovery was made with the electricity of the galvanic battery, but it is equally true when a strong current is obtained from the common electrical machine. An electric spark sent along a conducting wire passes too quickly to move the needle, and a current produced by the electrical machine does not appear to contain a sufficient quantity of electricity to act upon the needle, or rather to show its action. If the electrical effect of the current, however, is multiplied, its action upon the needle becomes apparent. In order to do this we must use, as Dr Colladon first did with success, Schweigger's multiplier, which is shown in fig. 11, where ABCDE is the wire which conducts the electrical current, bent several times, and covered with three folds of silk for the purpose of insulation. The needle NS is then inclosed within the coils of the wire, and the effect of the current upon it is obviously quadrupled by the *four* coils of the wire which surround it. The coils should be as near to each other as possible; and as they can be repeated a great number of times, the multiplication of the effect is almost unlimited. The needle is suspended by a single fibre of silk, and the sensibility of the instrument may be increased by using a magnet for the purpose of diminishing the directive power of the needle. When Dr Colladon brought the two ends of the wire of this apparatus to the two conductors of an electrical battery of 4000 square inches, so as to make the discharge go a little way through the air before it entered the wire, a current of sufficient strength and of some duration was obtained, which produced a considerable deviation in the needle. Dr Colladon also obtained a deviation of several degrees with this multiplier, by means of the electrical current obtained from an electrical machine.

Fig. 11.

Experiments of Dr Faraday.

These interesting experiments of M. Colladon have been amply confirmed and beautifully extended by Dr Faraday. Although MM. Arago, Ampere, and Savary had witnessed a successful repetition of M. Colladon's experiments, yet the conclusions to which they led were doubted by some and denied by others. Dr Faraday was therefore induced to repeat them with great care. He employed for this purpose the electrical machine, battery, and discharging train already described (see page 596).

The galvanometer which he used was sometimes a single one, consisting of sixteen or eighteen convolutions of copper wire covered with silk, and sometimes a double one, consisting of two independent coils, each containing sixteen feet of silked copper wire. The glass jar which covered the galvanometer and supported the needle was coated inside and outside with tinfoil, the upper part (left uncoated for the purpose of examining the motions of the needle) was covered with a frame of wire-work with numerous sharp projecting points. When this frame and the two coatings were connected with the discharging train, an insulated point or ball, connected with the machine in its most active state, could be brought within an inch of any part of the galvanometer, without the inclosed needle being affected by any ordinary electrical attraction or repulsion.

Dr Faraday expected, by means of the retarding power of bad conductors, to obtain from ordinary electricity the powers of voltaic electricity. After the connections were properly made, a battery charged positively by about forty turns of the machine was discharged through the galvanometer, when the needle immediately moved. By repeating this experiment when the needle was vibrating, its vibrations were extended to above forty degrees on each side of the line of rest: on reversing the galvanometer the needle was equally well deflected in the opposite direction, the deflections being in the same direction as if a voltaic current had passed through the galvanometer, the positive surface of the battery coinciding with the positive end of the voltaic apparatus. Similar effects were obtained by taking the electrical current directly from the prime conductor, and dispensing with the battery altogether. When the electricity, too, was passed through an exhausted receiver to imitate the aurora borealis, and then through the galvanometer to the earth, it was equally efficacious in deflecting the needle.

From these and other experiments, Dr Faraday concludes that a current of common electricity, whether transmitted through rarified air, water, brine, acids, and other imperfect conductors, or through wire, or by means of points in common air, is still able to deflect the needle (the only thing necessary being to allow time for its action), and is just as magnetic as a voltaic current.

As it is by the galvanic battery, however, that this subject has been studied, we cannot pursue it any farther at present, and must refer our readers to the articles already mentioned, in which a full view of this new science will be given.

Sect. VI.—*On the Effects of Electricity upon Animal Bodies.*

Influence of electricity on animal bodies.

The influence of electricity on the human frame, whether it is administered in small quantities so as to excite and surprise us, or in the more powerful and awful form of a stroke of lightning, must be well known to the least informed of our readers.

When any part of the body receives an electric shock, a disagreeable sensation is felt in the place; and, according to Dr Robison, it is sharper when taken from a long wire than from a large body. When the human frame forms part of the electric circuit, or when the charge of a Leyden phial is made to enter the body at one hand and pass out of it at the other, a violent concussion or shock is felt along the line of its passage across the breast and through the arms. This electrical shock, and the involuntary motion which accompanies it, arises no doubt from the obstructions which an imperfect conductor like the human body, composed of fluids and solids of different conducting powers, presents to the free passage of the electric fluid. If the charge is increased, the patient through whom it passes falls down under its influence, and suffers a temporary suspension of vital action; and if it is increased to a still greater degree, it will produce instantaneous death. This case is frequently exemplified when persons are killed by lightning; and a very remarkable instance of the laceration of the human body occurred several years ago which could have arisen only from an obstruction to the free passage of the fluid. The case to which we refer presents us with a most singular variety of action exhibited by the lightning in passing through animal bodies; and it is so interesting, and so well described by Mr B. Boddington, the father of the gentleman who was struck with the lightning, that we shall present our readers with an abstract of it.

The electrical shock.

Singular effects of lightning.

On the 13th of April 1832, Mr and Mrs T. F. Boddington left Tenbury, occupying the hind barouche seat of their post-chariot, the servants being in the inside. About half past three o'clock, with the sun shining, and a serene sky, they observed a dark cloud to arise in the direction of their route. Soon after a clap of distant thunder was heard, but no lightning was seen. A few drops of rain having begun to fall, Mr Boddington put up an umbrella, and, after giving it to his wife, he put up another, and when he was in the

Phenomena and Laws.

Singular effects of lightning.

act of extending the latter, a flash of lightning struck them both senseless, threw the horses on the ground, and cast the post-boy to a distance. One of the servants, after recovering from his alarm, looked out of the window, and saw the head of Mr Boddington hanging over the seat, and apparently lifeless. Jumping from the carriage, he raised his master's head, and found his clothes on fire, while Mrs Boddington was standing up tearing off her bonnet and shawls. She had neither seen the flash nor heard the thunder, but felt a sense of suffocation, and was putting off her things to obtain air. She and the servant then proceeded to extinguish the fire, which was still consuming her husband's dress. The lightning, passing down through the umbrella, penetrated through the bonnet into Mrs Boddington's neck, and zigzagged along the skin of her neck to the steel busk of her stays, leaving a painful but not a deep wound, and affecting the hearing of the left ear. From the lower end of the busk the lightning pierced through all the garments down to her thighs, where it made wounds on both; but the one on the left was so deep and so near the femoral artery, that the astonishment is she escaped with her life, the hæmorrhage being very great. None of her clothes were burnt, notwithstanding their inflammable nature, nor did any of her wounds present the appearance of burns. Mr Boddington, after remaining insensible for ten minutes, revived, and felt a pain all over him. The main force of the shock passed down the handle of the umbrella to his left arm, though a portion of it made a hole through the brim of his hat, and burnt off all the hair that was below it, along with his eye-brows and eye-lashes. The fragments of the burnt parts falling into the eyes, deprived him nearly of sight for two or three days. The electric stream shattered his left hand, melted his gold shirt-buttons, and tore the clothes in a most extraordinary manner, forcing parts of them, with the buttons, to a distance, and inflicting a deep wound under their position on the wrist. The arm was laid bare to the elbow, a severe wound was made in his body, and every article of his dress torn away as if by gunpowder. It then passed to the iron of the seat, wounding his back, the whole of which was literally flayed. The horse rode by the postilion was killed. A very striking difference was observed in the wounds of Mr and Mrs Boddington. Hers were fractures of the flesh. His, on the contrary, whether deep or shallow, were all burns, and had a white and blistered appearance. No wound was visible on the dead horse, excepting an indentation on the head where the fluid entered, discolouring the spine in its passage.

Experiments of Van Marum on eels.

For the purpose of determining in what manner death is produced by a powerful electric discharge, Van Marum sent the electric shock through eels one and a half and three and a half feet long. The smaller eels were instantly killed when the shock was sent through their whole body; but when the charge was only sent through individual parts, these parts only lost their irritability, while the rest retained it. When the shock went through the upper and fore part of the head of the large eels, the under jaw, as well as the muscles of the neck and belly, and even the lower part of the body, preserved their irritability, while the parts which conveyed the charge had totally lost it. When smaller shocks were sent through warm-blooded animals, similar effects were observed; and hence it has been inferred that the circulation of the blood cannot take place when such an effect has been produced, and that the suspension or destruction of life must arise from this cause. When the shock does not affect the large arteries the animal may recover, provided that the spinal marrow and the cerebellum are not injured.

Various experiments have been made by Mr Morgan and others, with the view of ascertaining the influence of electricity on the animal functions. Mr Morgan found that if the diaphragm forms part of the circuit between the inside and outside coating of a jar containing two square feet, the lungs will make a sudden effort, followed by a loud shout. When a small charge is similarly applied, a violent fit of laughter is always produced, even on the gravest persons. A strong charge transmitted through the diaphragm is frequently accompanied by tears and sighs, and sometimes by fainting. When a strong charge is sent through the spine of a person standing, he will frequently either drop on his knees, or fall prostrate on the floor. A strong charge having been transmitted accidentally through Mr Singer's head, he felt the sensation of a violent but universal blow, which was followed by transient indistinctness of vision and loss of memory, but no permanent injury was received. When the charge of a battery is sent through the head of a bird, its optic nerve is always injured or destroyed; and when a smarter shock is given to a larger animal, a tremor and depression, with a general prostration of strength, is produced.[1]

Experiments of Morgan;

of Mr Cavendish;

Mr Cavendish observed that the sensible shock depended more on the quantity than on the intensity of the charge, a double degree of intensity with only half the quantity invariably producing a less powerful shock. According to Volta, only a little more electricity is necessary to produce an equal shock from a larger surface A surface, for example, 16 times as large required only an elevation of the electrometer to one-tenth of the number of degrees. Dr Robison informs us that the shock obtained from a small charge given to a large surface, yields a less unpleasant shock than a large charge given to a small surface. As these observations, however, depend upon individual feeling, and as it is known that different persons are affected in very different ways with the same degree of electricity, they may not be generally correct.

of Dr Robison.

Effects of electricity on the pulse.

The influence of electricity on the pulse has been examined by different authors, though with some variety of result. M. Trembley found that the arterial pulse was quickened in persons electrified. M. Boze was of the same opinion; but the Abbé Nollet could not discover any increase in the rapidity of the circulation of various animals which he electrified. Cavallo, on the contrary, informs us that an experienced medical electrician assured him that, "in a diseased state of the body, an obvious acceleration of the pulse was observed to result from the application of electricity."

Experiments of Nollet.

In the experiments made by M. Nollet, his attention was directed to other points besides the state of the pulse. His experiments were made with birds, cats, and the human subject; and having selected and carefully weighed pairs of the animals, he communicated to them a current of electricity for some hours, when they were again weighed. The loss sustained was ascribed to perspiration. The general result was, that the animal which was electrified was always found to be lighter than the one which was not. The persons who submitted to these experiments suffered no inconvenience from them. They experienced a slight degree of exhaustion, and an increase of appetite, but none of them found themselves sensibly warmer.

Experiments of Van Marum.

In order to settle these questions respecting the influence of electricity on the pulse and on insensible perspiration, Van Marum selected *eleven* persons, and repeated the experiment *four* times upon each, with negative as well as with positive electricity. They were placed in a room so remote from the machine that they could not hear the noise which was made in working it. They were placed on insulating stools, and their pulse was felt and carefully

[1] Dr Young observes, that a minute tremor communicated to the most elastic parts of the human body, particularly to the chest, occasions a nervous agitation, not unlike the effect of weak electricity.

Phenomena and Laws.

counted both when the machine was in motion and at rest. The general result was, that no decided acceleration was observed, a few additional beats having taken place in some cases. In general, however, *there was a great irregularity in the pulse.*

The next experiment of Van Marum was a very interesting one. He placed a boy eight years old in one scale of a delicate balance, which scale was insulated by means of a silk cord. The boy being connected with the conductor, the balance was brought to a state of exact equilibrium. Having determined that the boy, previous to being electrified, lost 280 grains in an hour, he electrified him, and found that the loss was 295. In another experiment the boy lost 330 grains before, and 310 after being electrified. A girl seven and a half years old lost 180 grains before, and 165 after being electrified. A boy eight and a half years old lost 430 grains before, and 290 after being electrified. A boy nine years old lost 170 before, and 240 after being electrified. As this boy had remained very quiet during the experiment, the increase was ascribed to electricity, and the experiment was carefully repeated. He now lost 550 grains before, and 390, 330, 270, 550, and 420 after being electrified. Hence it appeared that the insensible perspiration had rather decreased than augmented.

Medical electricity.

The powerful influence of electricity on the human frame led the more sober part of the medical profession to view it as a valuable auxiliary in the healing art, while those who were more sanguine regarded it as an universal medicine, which might be resorted to in every form of disease. Charlatans of every degree found the electrical machine a lucrative article of trade; and there were not wanting well-meaning enthusiasts who contributed to prolong the reign of medical electricity.

But though electricity has not yet taken up a position in the healing art, there can be no doubt that in various disorders its application has been found advantageous, and that patients have, in a particular class of diseases, experienced instantaneous relief.

Electrical machine for medical purposes. Plate CCXXIX., fig. 16.

The machine used for medical purposes should have sufficient power to yield a continued current of strong sparks. The diameter of the plate in a plate machine should be about twenty inches, and that of a cylinder about ten or twelve inches. The only apparatus necessary is a jar fitted up with Lane's electrometer (see Plate CCXXIX., fig. 16), and a pair of directors, each consisting of a glass handle surmounted by a brass cap, with a wire a few inches long, carrying a ball at its extremity. A wooden point is sometimes substituted for this ball. When it is required to pass a shock through any part of the body, the directors are applied at the opposite extremities of the part, one director being connected by a wire with the inside coating, and the other with the outside coating of the jar, or, what is the same thing, with the receiving ball of Lane's electrometer, previously placed at such a distance from the ball of the jar as to yield a charge of the proper magnitude. When sparks are to be administered, it is done with the director and brass ball; but when the organ is very delicate, such as the eye, a stream of electricity is thrown upon it from the wooden point, held at the distance of about half an inch. An insulating stool, capable of holding a chair for the patient, is also necessary. In certain cases a brass plate, communicating with the inside of the jar, is placed in the bottom of the chair, so as to apply itself to the lower part of the body, when the electricity is required to pass through the abdomen or adjacent parts.

Sect. VII.—*On the Effects of Electricity upon Vegetable Bodies.*

It has been distinctly shown by Priestley, Ingenhousz, and Sennebier, but especially by Theodore Saussure, that the various parts of plants act upon atmospheric air; that they insensibly disengage a large quantity of carbonic acid at the expense of the oxygen; and that, owing to some combination within the plant, they sometimes exhale pure oxygen. Now, as all carbonic acid has vitreous electricity, this exhalation of the acid from the plants ought to furnish an abundant supply of it to the atmosphere. M. Pouillet, of whose researches we have already given an abstract, has placed this truth beyond a doubt.

Electrical Apparatus.

Effects of electricity on vegetables.

From this fact alone we might reasonably infer that electricity performs an important function in the phenomena of vegetation; but so little attention has been paid to this subject, that we have some hesitation in laying before our readers the very imperfect and unsatisfactory experiments which have been recorded. The best experiments, indeed, have entirely a negative character; and the general result of them is given when we say that electricity appears to have no decided efficacy as a stimulus to vegetable life.

The recent discoveries, however, which have been made on endosmose and exosmose by M. Dutrochet, render it extremely probable that an electrical action is the cause of the ascent of the sap in plants; but as M. Poisson has ascribed these curious facts to capillary action, and other philosophers to other causes, we must wait for further experiments before we can treat this subject as a branch of electricity.

PART II.

DESCRIPTION OF ELECTRICAL APPARATUS.

Electrical apparatus.

In the preceding part of this treatise we have already had occasion to refer to several pieces of electrical apparatus, and particularly to two or three varieties of the best machines for generating electricity by friction. Notwithstanding this slight anticipation, however, we must resume the subject at some length, on account of its great importance in a popular and practical view of the science.

The various kinds of electrical apparatus may be classed under the four following heads:—

1. Instruments for generating and collecting electricity.
2. Instruments for accumulating electricity.
3. Instruments for indicating the presence of electricity, and measuring its quantity.
4. Instruments for miscellaneous purposes.

CHAP. I.—DESCRIPTION OF INSTRUMENTS FOR GENERATING AND COLLECTING ELECTRICITY.

Instruments for generating electricity.

The instruments which belong to this chapter are, electrical machines, atmospherical conductors, and electrophori.

Sect. 1.—*Description of Electrical Machines.*

The simplest of all pieces of apparatus for generating electricity is a tube or rod of glass, which, when rubbed with a piece of woollen cloth, will yield as much electricity as will charge a jar in a short time. In consequence, however, of the labour which attends this operation, it has been usual to turn a sphere or cylinder of glass round an axis by a simple winch, or by a double wheel and band, for the purpose of generating electricity rapidly, and without fatigue to the operator.

We have already exhibited two of these machines in Plate CCXXII., figs. 1, 2, 3, 6, & 7, and described their general construction. It is easy to modify this construction in various ways;—and for particular purposes and particular classes of experiments particular forms of the machine may be most convenient: But as the philosopher is best capable of introducing such modifications for his own use, we shall not occupy our pages with the descriptions of electrical machines which have sprung more from the fancy and caprice of individuals than from the wants of the science.

Electrical Apparatus.

There can be no doubt that the plate-glass machine is the most commodious and the most powerful form of the electrical machine. But whether the glass has the form of a plate or a cylinder, it should be of that kind which has the least quantity of alkali in its composition. Bohemian glass, and glass pretty old, is preferred to modern glass. It has also been stated that a glass plate will derive great electrical power by a considerable exposure to the sun's rays.

We have already described, and given representations of very excellent plate-glass machines in Plate CCXXII., figs. 1, 2, and 7, and in Plate CCXXIII., figs. 1-5, of the last of which we shall give a fuller description; but we have reserved to the present chapter the description of the best form of the electrical machine with which we are acquainted, and which we owe to the ingenuity of Sir Snow Harris, F.R.S., Plymouth.

1. *Description of Sir W. Snow Harris's Electrical Machine.*

Sir Snow Harris's electrical machine. Plate CCXXVII., fig. 7.

This machine, which is shown in perspective in Plate CCXXVII., fig. 7, consists of a circular disc of plate glass ZZ, three feet in diameter, mounted on a horizontal axis, resting on two horizontal supporters of mahogany. These supporters are themselves sustained by four vertical mahogany columns, fixed upon a firm frame as a base. To the lower side of this frame are fixed four legs M, N, O, P, upon which the whole machine rests; and these legs again rest upon another steady frame RST, furnished with rollers, so as to move it easily into any required position, and likewise with three levelling screws, RST, for placing it horizontally. By these means the machine may be so adjusted and fixed that the axis of the plate of glass, which has a free motion backwards and forwards in the holes in which it turns, may not tend more to one side than to the other, and occasion an unequal action on the rubbers. The rubbers, which are four in number, are insulated on pillars of glass A, B, one placed at each extremity of the horizontal diameter A, B, of the plate. The positive conductor CBD projects in a vertical position in front of the plate ZZ, while the negative conductor passes in a curvilineal direction behind, and connects the rubbers of each side.

The plate of glass is turned by an insulated handle, immediately in front of which is placed a short index, which is fixed to the axis, and which moves over a graduated circle L, attached to the horizontal part of the frame, and through the centre of which the axis passes. In this manner the number of revolutions of the plate may be accurately registered.

In order to strengthen the centre of the plate, two smaller plates are cemented to each side by varnish; and a small stop is inserted into the axis, to prevent the pressure from increasing beyond a certain point.

Fig. 7.

When the machine is used for ordinary purposes, the conductors shown in fig. 7 are employed; but when it is employed to accumulate electricity, the conductors should have the smallest extent possible, and, excepting at the receiving points, where they collect the electricity from the edge of the silk flaps about H, H, they should be covered with sealing wax. In this case the positive conductor is formed of small straight tubes, as shown in fig. 8, and its extremities terminate in balls of varnished wood, through the substance of which the metallic communications pass.

Fig. 8.

2. *Description of Van Marum's Electrifying Machine.*

Van Marum's electrical machine. Plate CCXXIII., figs. 1-5.

This machine, to which we have made a brief reference in Sect. III. Chap. II. Part I., is represented in elevation and in section in figs. 1 and 2 of Plate CCXXIII. The plate of glass AB, which is thirty-one inches in diameter, is sustained by a single pillar E, at the upper extremity of which are two similar brass collars I, I, one of which is shown separately in fig. 4. The horizontal axis MN rests upon these collars, and this axis carries a counterweight L, in order to balance the plate of glass and its appendages, and thus equalize the friction on the collars. The rubbers, which cannot be seen in the section, fig. 2, are shown at *m*, *n*, fig. 1. The pair at *m* is attached to the ball O, and supported by the glass pillar *e*; and in like manner the pair at *n* is attached to the ball P, and supported by the glass pillar *f*. A horizontal section of the rubbers and balls is shown separately in fig. 3. A semicircle of brass CD is attached to an axis *g* that turns on the ball G, resting on the pillar F, so as to give the conductor CGD a motion round that axis. Collectors six inches long and two and a half in diameter are placed at C and D, to collect the electricity from the revolving plate AB. At the outer end of the axis *g* is a copper tube H*h*, terminating at its lower end in a ball H, and its upper end in a smaller ball *h*, two inches in diameter, which, screwing into G, will fix the tube H*h* in any position round *g*. An arch of brass wire *cId*, half an inch in diameter, is fixed to the end of the bearing piece K, and moves round I into any given azimuth, so as to be placed, as in fig. 1, opposite the rubbers *m*, *n*, or at right angles to them. In like manner, the conductor CGD can be placed either horizontally, so that the collectors C and D may be opposite the rubbers *m* and *n*, or vertically, as shown in fig. 1. By this apparatus it is easy to produce either positive or negative electricity. In the position of the conductor shown in fig. 1, where CGD is at right angles to the rubbers, and where the rubbers are connected with the ground by the arch *cId*, and by the wire KK, fig. 2, the conductor G will give *positive* electricity; but when we wish *negative* electricity, the conductor CGD is placed horizontally, with its collectors C, D opposite the rubbers, and the arch *cId* is placed vertically, so as to insulate the rubbers.

A mahogany cap T covers the metallic caps of the supports, in order to insulate them more perfectly. A hollow ring of mahogany, VX, is, for the same reason, made to cover the metallic socket into which the support is inserted. In fig. 3, *a*, *b*, *a*, *b*, are four pieces of gum-lac. In figs. 1 and 2, W is the handle by which the machine is wrought.

3. *Description of Hare's Electrical Machine.*

Hare's electrical machine. Plate CCXXII., fig. 7.

This machine, which we have previously noticed, differs from those generally made, in having its glass plate horizontal; and it is considered by its inventor, Professor Hare of Philadelphia, as giving negative electricity in a way preferable to that in which it is obtained in Van Marum's machine. The glass plate MN, thirty-four inches in diameter, is supported on an upright iron bar PR, about an inch in diameter, and covered by a stout glass cylinder, sixteen inches high and four and a half inches in diameter, open only at the base, through which the bar is introduced so as to form its axis. At the top of the bar PR is a block of wood turned to fit the cavity at the apex of the cylinder, and cemented therein. The external apex of the cylinder, is fixed by cement into the brass cap which carries the plate. The glass cylinder, which is liable to no strain, effectually insulates the plate from the iron axis PR. The brass cap seen at P is surmounted by a screw and flange, which, with the aid of a corresponding nut and discs of cork, keeps the plate firm. The wheel W, driven by a handle, communicates by means of a band with another wheel about twenty inches in diameter, placed on the iron axis RS.

"Nearly the same mode of insulation and support," says Dr Hare, "which is used for the plate is used in the case of the conductors. They consist severally of arched tubes of brass (ABC, DEF), of about an inch and a quarter in diameter, which pass over the plate from one side of it to the other, so as to be at right angles to, and at a due distance

Electrical Apparatus.

from, each other. They are terminated by brass balls and caps, which last are cemented on glass cylinders of the same dimensions nearly as that which supports the plate. The glass cylinders are suspended upon wooden axes, surmounted by plugs of cork turned accurately to fit the space which they occupy. The cylinders are kept steady below by bosses of wood which surround them. In this way the conductors are effectually insulated, while the principal strain is borne by the wooden axes."

The collectors are shown at MN in connection with the *positive* conductor ABC, and the rubbers are shown between P and the balls D and F in connection with the *negative* conductor DEF. The advantage of this form of the machine over that of Van Marum is, that the two conductors are permanently fixed in their places, and that positive and negative electricity can be at any time obtained without any change in the machine. Dr Hare considers the band as of advantage in preventing the plate from being cracked by any hasty effort to put it in motion when it adheres to the cushions, as it often does. Dr Hare uses a winch on the other side of the wheel, so that two persons, or one with both hands, may drive it.

The great expense of large cylinders and plates of glass, and their liability to injury, have induced artists to construct electrical machines of different substances. M. Walckiere de St Amand of Brussels constructed a machine of extraordinary power, which consisted of a web of varnished silk twenty-five feet long and five feet wide, revolving upon two wooden cylinders covered with woollen serge. During the revolutions of the cylinders, the silk moves between two cushions, each seven feet long and two inches in diameter, covered by cat's skin or hare's skin, and moveable so as to vary the friction. The machine was driven by four men, and it had so great power that it gave sparks fifteen inches long, and nobody durst take a spark from it but with the shoulder and elbow.

Machines of silk webs;

Dr Ingenhousz constructed machines with discs of pasteboard four feet in diameter, and soaked in copal or amber varnish dissolved in linseed oil. They were covered with the same varnish, and were mounted upon an axis or flat board, three inches broad, and covered with flannel or hare's skin, being placed between each two discs, so as to act as a rubber. Sparks one and even two feet long were given out by the front disc when the knuckle was presented to it.

of varnished pasteboard;

Wooden discs, and cylinder discs of gum-lac partly immersed in mercury, which acted on the rubber, and stretched varnished ribbons, have been all used in the construction of electrifying machines, but it would be an unprofitable task to describe them.

of wooden discs.

4. *General Observations on the Construction and Use of the Electrical Machine.*

Observations on the electrical machine.

Although, in fine dry weather, and in a warm and dry place, a good electrical machine may be brought into an excellent state of action merely by wiping it with a warm linen cloth and afterwards with a silk handkerchief, yet in a different state of the atmosphere, and in humid apartments, every precaution is necessary to insure the vigorous and steady action of the machine. By turning the machine before a fire, or placing it in a current of heated air, or, as Dr Faraday suggests, by placing it over a sand-bath or a hot iron plate whose temperature does not exceed 212 degrees, the different parts of the machine will be thoroughly dried and heated without affecting the cements.

Methods of heating the machine.

We have already described (see page 536) the improvement of Mr Ronalds, who heats the inside of the machine, &c., by a spirit-lamp. Dr Faraday recommends the heating of a cylinder machine by placing a chemical Argand lamp with a low flame beneath the cylinder, and to support a plate of metal nearly six inches square about an inch above the chimney of the lamp. This plate, by being heated, varies the air above it, and produces a large moderately heated current, which encircles the cylinder and thoroughly warms it. Care must be taken not to heat the cylinder in spots, but to bring it, and especially the insulating parts, to an uniform temperature, which shall never be sufficient to melt the cement which is used in any part of it.

The state of the rubbers requires particular attention. They must be carefully freed from dust, and supplied with a soft and uniform coating of amalgam, which should always be rubbed in a mortar with tallow previous to being used. Large spots of amalgam should be removed from the cylinder or plate, either by the nail or a piece of wood. Dr Faraday remarks that a few spots of amalgam rather increase than diminish the activity of the machine, and that the silk which proceeds from the rubber is better when impregnated with amalgam than when free from it. Dr Faraday adds that it is often useful to hold a piece of silk, with some amalgam adhering to it, against the revolving plate or cylinder, and also to rub the surface of amalgam on the rubber with the same amalgamated silk. When the machine is thus put into good action, and the prime conductor removed, it should discharge a continued series of brushes from the edge of the silk, and abundance of sparks flying round the glass.

Armstrong's Hydro-Electric Machine.

Armstrong's hydro-electric machine.

This powerful electrical machine, the history of which we have already given, is represented in the annexed figure, where AB is a steam-boiler made of the usual material, $6\frac{1}{2}$ feet long, and $3\frac{1}{2}$ broad, or of a less size if required. It is

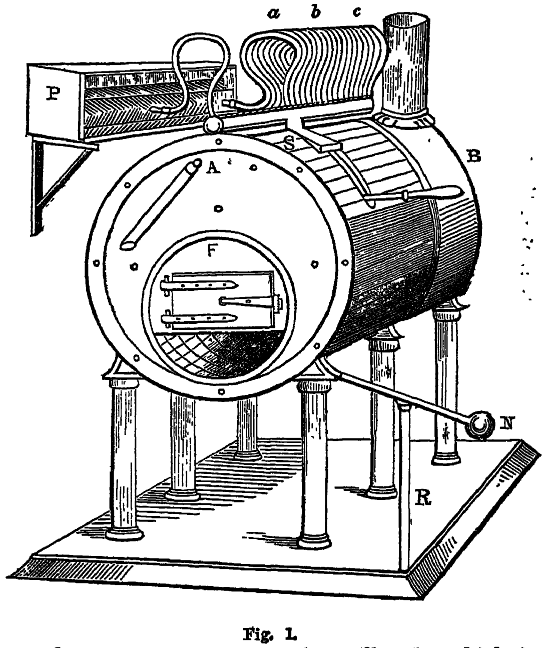

Fig. 1.

supported on four or six strong glass pillars by which it is insulated. The steam generated by the heat of the furnace F, escapes from the common steam pipe by a stop-cock S; and issues through a great number of bent iron tubes *a*, *b*, *c*, terminated in jets or adjutages of box-wood. A conductor N insulated by a glass rod R projects from the boiler, in order to collect from it the excited electricity, and another conductor P is placed in front of the jets to carry off the opposite electricity of the steam, and prevent it from neutralizing that of the boiler. The tubes are often inclosed in a box containing water for the purpose of cooling the tubes, which are kept wet, not by contact with the water, but by cotton threads which carry it up to them by capillary attraction. In this way minute drops of water are pro-

Electrical Apparatus.

duced, which being carried away by the steam produce the electricity by their friction upon the wooden adjutages. According to Dr Faraday, the steam performs no other part than that of making the particles of water rub upon the wood through which they pass. A magnificent hydro-electric machine has been erected at the Faculty of Sciences in Paris, with no fewer than 80 jets. Its enormous sparks succeed one another so rapidly as to form continuous and brilliant jets about a foot in length, and some inches in breadth.

Sect. II.—*Description of the Electrophorus.*

Electrophorus of Volta. Plate CCXXVII., fig. 9.

This ingenious instrument, which was invented by the celebrated Volta, is shown in Plate CCXXVII., fig. 9. It consists of a circular metallic disc A, or a plate of wood covered with tinfoil, having an insulating handle of glass screwed into a nut E, made of wood or brass. The plate A is called the *upper conductor*, or *cover*. The next plate B, called the *resinous plate*, consists of a plate half an inch thick, composed of equal parts of shell-lac, common resin, and Venice turpentine, poured when hot upon a marble or stone table. The next plate is a metallic one C, called the *lower conductor*, or *sole*, which may be either separate or not from the *resinous plate* which rests upon it. The edge of the first plate A must be pretty thick, and made smooth and round. The following is the method of generating electricity with this apparatus.

The *cover* A being held in the left hand, rub the upper surface of the *resinous plate* B with a piece of dry fur, or whip it with a fox's tail or stripe of cat's skin. It will thus be excited *negatively*. Place the upper conductor above the resinous plate, and while it is there touch it with the finger, and then raise it by its glass handle. It will exhibit signs of positive electricity, and will yield a spark either to the knuckle or to the knob of a Leyden phial. If the cover A is again placed upon B, and, after being touched, again raised, it will give another spark, and *twenty* of these sparks will charge a Leyden jar of a moderate size. If the upper conductor A is not touched by the finger when placed upon B, it will exhibit, when raised, very faint, if any, traces of electricity. Now, as the resinous plate B continues, without any new excitation, to charge the upper conductor A, it is manifest that its electric condition is not destroyed by the contact and removal of A; and as it is necessary to connect the upper conductor with the ground, by touching it previous to its being raised, it is obvious that the electricity acquired by A is derived from its contact with B.

Fig. 10.

In order to explain the theory of the electrophorus, let us insulate the *lower conductor* C, by placing it on a glass stand, as in fig. 10, and let this conductor communicate with the pith balls of an electroscope. As soon as the upper surface of the cake B is excited, the pith balls will diverge with negative electricity. The negative electricity developed by the excitation of the upper surface has decomposed the natural electricity of C, by attracting the positive part and repelling the resinous part into the electroscope where it is indicated. If we now touch the conductor C, its negative electricity is carried off, and the positive undergoes no diminution; but, owing to the escape of the negative portion, the balls will collapse. If we now make the upper conductor A approach to B, and rest upon it, touching it at the same time with the finger, so as to connect it with the ground, the positive electricity of the cake B will decompose the natural electricity of A, repelling its negative electricity to the earth through the finger, and attracting its positive portion to its lower surface. This positive electricity of A attracting the negative electricity of the surface of B, and repelling the vitreous electricity of C, thus doubly tends to diminish the force by which this positive electricity is rendered latent or detained. Some of it, therefore, will be set free, and the pith balls will diverge with positive electricity, the divergence increasing as the conductor A comes nearer and nearer to the plate B. But as the positive electricity of the lower conductor has a tendency to repel the positive electricity with which we wish to charge the upper conductor A, we must cause the lower conductor C to communicate with the earth, as in fig. 9. By this means the electricity of C is reduced to its natural state, and the electricity of the upper surface of the cake B renders latent the maximum quantity of positive electricity on the upper conductor B.

Fig. 9.

Although the air produces a gradual dissipation of the electricities which are not rendered latent in an excited electrophorus, yet a well-constructed electrophorus will remain for months in full energy.

Lichtenberg's electrical figures.

M. Biot has ingeniously applied the principle of the electrophorus to explain what have been called the figures of Lichtenberg. If, when the electrophorus is charged, we raise the conductor A, and replace it on the cake B, by making it rest obliquely and upon its edge, then its positive electricity, accumulating itself wholly in the part which touches B, will become much stronger. It will escape from A, and will completely neutralize the negative electricity of the places towards which it goes, and after some contacts thus repeated upon different parts of the cake B, it will be all discharged. Hence we may deduce the following curious experiment:—Instead of bringing back upon the negative electricity the positive which it has developed by its influence, carry it to another resinous cake B′, in its natural state. It will likewise attach itself to the surface of this cake, which will become positively electrified, and be capable in its turn of developing by its influence negative electricity. When the second cake B′ is thus charged, place upon its surface a disc of metal. We shall then have an electrophorus of an opposite kind to the first; and if this last is used to charge a third cake B″, the latter will have negative electricity; and in this way we may have any number of cakes, which will be electrified positively and negatively alternately. By this process we may electrify each surface only in certain parts, by attaching to the conductor A a rod and metallic button. If we then touch the resinous cake with this button, the electricity will be carried wholly to the point of contact. These points may be so chosen as to form the outlines of any regular or picturesque figures. In order to render these forms or pictures visible, we have only to strew on the surface of the resinous cake some light powder formed by a non-conducting substance, such as pounded resin or sulphur. The small particles of the resin, for example, will attach themselves only to the electrified spots; so that, by inverting the plate, all the rest will fall down by their own weight. These small particles affect regular and different arrangements, according to the nature of the electricity which makes them adhere; so that, by forming figures with the two electricities in different parts of the same plate, we obtain at the same time two sorts of figures.

Lichtenberg's method of making these figures visible is exceedingly beautiful. Having triturated sulphur and minium or red lead together in a mortar, so as to have a mixture of a yellow and red powder, he traced his figures on the resinous cake with the knob of a jar charged with vitreous electricity, and repeated them with the knob of a jar charged with resinous electricity. The compound powder being now projected, either with a powder puff or by means of a pair of bellows, upon the cake, the particles of sulphur which are electrified positively by trituration will attach themselves to the negatively electrified spots, while the negatively electrified particles of red lead will adhere to the positively electrified spots, so as to form a series of red and yellow figures when the cake has been inverted, and the rest of the powder has fallen from it. Many beautiful variations of this experiment have been devised;

Electrical Apparatus.

and Mr Bennet has shown how to make the figures permanent, by transferring them to paper.

When this experiment was first made, some German philosophers observed that the powder of rosin had sometimes a progressive motion which was not regular, and a new theory was the consequence of this. It was found, however, that they were very small insects of the genus *acarus* which happened to be in the powder, and which walked over the surface of the plate.

When well made and properly used, the electrophorus is a very powerful and useful instrument. Dr Klincock of Prague has shown, that if we transfer alternately the upper conductor from one resinous cake to another, and touch it after it is placed on the cakes, both cakes continually acquire more and more electricity, so that the upper conductor returns from either plate quite overcharged; and Leyden jars may be so strongly charged by them as to burst by the charge. The conductor returns from one plate charged with positive, and from the other charged with negative electricity.

M. Cavallo informs us that an electrophorus made of sealing-wax spread upon a thick plate of glass six inches in diameter was capable, when once excited, of charging a Leyden jar several times in succession, and so strongly as to perforate a card with the discharge. The upper conductor, when separated from the plate, was sometimes so strongly electrified that it darted strong flashes to the table upon which the electric plate was laid, and even into the air.

2. *Mr J. Phillips' Modification of the Electrophorus.*

Phillips' electrophorus. Plate CCXXVII., fig. 11.

As the contact of the operator's finger is of no other use than to connect the upper conductor with the earth, Mr John Phillips of York conceived the ingenious idea of producing the same effect by a momentary contact between the upper and under conductors. In effecting this he adopted three methods. The *first* consisted in raising a brass wire and ball from the lower conductor above the edge of the resinous cake, so that the edge of the upper conductor, or a brass ball upon it, may be brought in contact with it. This method answered very well with small instruments, in which the upper conductor can be easily directed to any particular point of the sole. In the *second* mode he fixed a narrow strip of tinfoil across the whole diameter of the resinous surface, so as to join the metallic sole or lower conductor. This construction answers perfectly, and is particularly suitable to large circles, whose upper conductors will infallibly touch some point of the metallic strip. The *third* method is to perforate the resinous disc quite through at the centre, and at any other point, and to insert in these perforations brass wires with their smoothest tops level with the resinous surface.

These three methods are represented in fig. 11, where *a* represents the ball in the *first* method, *b* the slip of tinfoil in the *second*, and *c, c, c* the conducting wires in the *third* and best method.

"On two of the largest electrophori," says Mr Phillips, "which I have made, both the second and third methods have been tried with equal success, but I much prefer the latter construction. The largest instrument has a cast-iron basis 20·5 inches diameter, resinous surface 19·75 inches, cover 16·25 inches. The resinous composition was made according to the directions in Mr Faraday's work on Chemical Manipulation. The cover is made of a plate of thin copper, strengthened at the edge by a thick brass wire, from which three radial brass wires pass to the upper part of a central brass tube. In consequence of the angle they thus form with the plane of the plate, they act as pretty strong braces to maintain its figure, and the whole is very light. This central brass tube receives a cylindrical piece of wood, into which the insulating glass handle covered with sealing-wax is screwed by its wooden foot.

"With ordinary excitation this instrument will yield loud flashing sparks two inches long or more, and speedily charge considerable jars. The cover can be easily charged and discharged fifty or a hundred times in a minute, by merely setting it down and lifting it up as fast as the operator chooses, or the hand can work. In charging a jar or plate, I placed one knob of the connecting rod near the insulated surface of the jar or plate, and the other some inches above the cover; then the cover being alternately lifted up and set down, the jar is very quickly charged.

"One instrument nine inches in diameter, which I have made from the second plan above described, has very often surprised me by its remarkable power of retaining electrical excitation.

"The following example is worthy of notice. Early in September 1832 this instrument was removed from a house in York, where it had been for some time laid by, and brought to my present residence, distant one third of a mile. It was placed on a shelf on my book-cases, where it remained untouched until the 23d March 1833, and was then taken down *covered with dust*. It was found to be in a state of feeble excitement, so as to give sparks, visible in the day light, nearly one fourth of an inch long."

3. *On Dr Faraday's Improvements on the Construction of the Electrophorus.*

Improvement on the electrophorus.

As the electrophorus is an excellent substitute for an electrical machine in the laboratory of the chemist, from its being capable, when in good order, of inflaming the greater number of explosive mixtures operated upon in eudiometers, Dr Faraday has given the following simple and ingenious methods of constructing this instrument.

He recommends the *cover* to be made of a piece of flat deal board one third or one half of an inch thick. This board is to be covered with pasted tinfoil laid on smoothly, particularly at the edges, and having all asperities rubbed down. The smoothest and flattest side being reserved for the lowest, a piece of glass tube seven or eight inches long is to be fixed on the centre of the other side for a handle; and towards the edge, on the same side, there should be fixed a piece of thick wire, about two inches long, bent outwards, and carrying a smooth metal ball at its upper end.

In order to make the resinous plate, a sheet of tinfoil one or one and a half inch wider than the cover is laid smoothly in the bottom of a flat dish, so that its edges may rise up all round, or in the inside of a hoop. Shell-lac, common resin, and Venice turpentine, in equal proportions, are then to be melted together in a metallic vessel, and kept in a state of fusion from 230 to 240 degrees of Fahrenheit, till the vapour has ceased to evolve, and the fluid is quiet. When it has thickened by cooling, it must then be poured quickly, to avoid the formation of bubbles, upon the tinfoil, so as to form above it a cake one third or one half of an inch thick. The tinfoil should then be trimmed round its edge, and the cake should rest upon or be attached, by its tinfoiled side, to a board, to serve as a base and prevent it from injury. Dr Faraday observes that the *cover*, instead of a board, may be a plate of tin turned up round a thick wire, so that no sharp edge or angle may be presented outwards; and that for the resinous plate may be substituted a sheet of thin crown glass, having for its metallic base a sheet of tinfoil pasted to it. He adds also, that a large plate of mica without fissures, and coated in the same manner with tinfoil on one side, makes an excellent electrophorus. When glass, however, is employed, it must be well warmed at first, and kept warm during the experiments. The glass should be excited by being *rubbed* with a piece of silk with some

Electrical Apparatus.

amalgam spread upon it. It should be passed briskly over its surface backward and forward, and finally slid quickly off at its edge, so as not to rest upon any one point of the glass, lest it should discharge that portion of its surface.

Use of the electrophorus.

To return, however, to the use of the electrophorus first described. The resinous plate, when warm and dry, should be placed horizontally on its board, with the tinfoil below, and connected by a wire or chain with the ground, or with a discharging train when it can be obtained. See page 596. A piece of warm flannel, doubled up loosely into a roll about ten inches long, is to be held in the hand by one end; and the other end, being swung round in an inclined direction with a quick motion of the wrist, should strike the surface of the plate obliquely each time it passes, so as to produce an effect between that of a rub and a blow. When the whole surface of the warm resinous cake has been thus struck, it will be excited to a considerable degree. The *cover* of the electrophorus, being previously warmed, must now be lifted by its glass handle and placed on the middle of the resinous cake; and if the knob or metallic ball of the cover be now touched, a spark will pass from it to the finger. The cover is next to be lifted by its handle in a horizontal direction; and when it is two or three inches above the plate, the knob upon it is again to be touched by the finger or a ball, when a spark stronger than the first will be obtained. The cover being again put down on the plate, a third spark will pass between the knob and the knuckle. The cover being again lifted as formerly, a spark as strong as the second may be taken from it. By repeating this process, similar effects may be obtained for a long time. The sparks which are taken by the knuckle after putting the cover down are negative, and those which are taken after lifting it up are positive. Hence we charge a jar either positively or negatively, according as we take the spark when the cover is up or down. In order to obtain strong positive sparks, the cover, when on the resinous plate, must be touched with the finger, which must be removed before the cover is lifted up; and to obtain the strongest negative sparks, the cover when raised should have all its electricity carried off by the hand or some other conducting body before it is again placed on the plate. As the cover ought to be in a state of good insulation, the handle should be made of sealing-wax and gum-lac, or if made of glass, it should be varnished with sealing-wax dissolved in alcohol.

SECT. III.—*Description of Conductors for bringing down Electricity from the Atmosphere.*

Conductors.

Various means have been adopted for collecting the free electricity of the atmosphere, either for the purposes of experimental investigation, or in order to defend buildings and ships from lightning. The apparatus for the first of these purposes is essentially different from that which is used for the last.

1. *Electrical Kites.*

Electrical kites.

When the lower atmosphere is charged with electricity, it is not difficult to collect it for the purposes of experiment; but in ordinary states of the air, or when the free electricity exists at some height above the earth, it is necessary to bring it down by means of a kite. For this purpose a schoolboy's kite is sufficient. It is only necessary to twist a copper wire round the hempen string. Dr Franklin covered the frame of his kite with a thin silk handkerchief, in order that it might the better sustain the violence of a thunder-storm. In order to compensate for this additional weight, he made the framework of two strips of cedar wood in the form of a cross. The string of the kite terminates towards the observer in a silk string or cord, which insulates the kite and its conducting string; and in order to protect the observer still farther, a safety chain has been sometimes suspended from the extremity of the conducting string, so as to reach the ground and carry off the electricity in case of its becoming too powerful.

Mr Cuthbertson sometimes found it necessary to use three kites all connected together. On one occasion when he could collect no electricity from the atmosphere with a kite having a string 500 feet long, he succeeded in obtaining it by adding other two kites, each of which had strings of the same length. Mr Cuthbertson likewise employed an apparatus for raising his kites, in which the strings were lengthened or shortened by coiling them round a drum.

2. *Exploring Conductors.*

Exploring conductors.

Read's hand-exploring rod.

One of the simplest instruments for collecting atmospherical electricity is the *hand-exploring* rod used by Mr Read. It was of the same material, length, and thickness as a common fishing-rod, and had small wire twisted round it from one end to another. Standing on an insulating stool, he raised the rod in a vertical position, and after a minute or two he touched with his other hand an electrometer, which indicated the nature and intensity of the electricity brought down. When the electricity thus obtained was very weak, he placed on the rod a lighted torch, keeping it as far up the rod as the strength of his arm would permit; and he always found that the flame attracted the electricity more powerfully than the end of the rod.

Read's fixed thunder rod. Plate CCXXVII. fig. 12.

Mr Read, however, found it necessary to use a fixed conductor or thunder-rod; and we have shown in Plate CCXXVII., fig. 12, the apparatus which he used in his experiments on the electricity of the atmosphere, of which we have already given some account. The principal part of it is a wooden rod AA, twenty feet long, one inch in diameter at the top, and two at the bottom. Into the lower end of it is cemented a solid glass pillar B, coated with wax, and twenty-two inches long. This pillar rests on a wooden pedestal C, carried by a bracket D. At thirteen inches above D, the rod passes through a glass tube F, coated with wax, and supported by a strong arm of wood E. A lining of cork lies between the rod A and the tube F, to prevent the latter from being broken when the rod is bent by the wind. Several sharp-pointed wires G stand out from the top of the tube. Two of them are of copper, about one-eighth of an inch thick, one of them being twisted round the rod to the right, and the other to the left, as shown in the figure, so as to reach the brass collar at the top of the lower funnel H, to which they are soldered. The use of the two funnels H, H is to defend the glass rods B, F from the weather. Through a hole in the wall at I passes a glass tube coated with sealing-wax, through which a strong brass wire passes from the rod at M into the room. At the end of the tube this wire passes through a brass ball L, two inches in diameter; and, after proceeding a little farther, it suspends from its extremity a pith-ball electrometer K, about twelve inches from the wall. A bell N, carried by a strong wire, is placed two inches from the brass ball L, three tenths of an inch in diameter, suspended from the nail O. The bell N, which has a metallic communication R with the moist ground, is rung by the ball L. Jars and other pieces of apparatus are placed when wanted upon the small shelf P; and all this part of the apparatus is protected from the weather by being inclosed in a wooden box.

Cavallo's atmospherical collector, fig. 13.

M. Cavallo's apparatus, called an atmospherical collector, merits a description here, on account of its simplicity and ingenuity. A common jointed fishing-rod AB, fig. 13, has its smallest joint replaced by a slender glass tube C, coated with sealing-wax. From a cork D at its outer end is suspended a pith-ball electrometer. A piece of string AHGI,

Electrical Apparatus.

is fixed to the end A of the rod, and supported at the point G by a piece of twine FG. When a pin at the end I of the cord is pushed into the cork D, the electrometer is uninsulated; but it is insulated for the purposes of observation in the following manner:—The pin being fixed in the cork D, and the rod held by the hand at A, it is held out of one of the highest windows. at an angle of about 50° or 60° to the horizon, and kept there for a few seconds. The cord is then pulled at H, so as to disengage the pin from the cork D, and the string drops into the dotted position KL, leaving the electrometer insulated and electrified in a state opposite to that of the atmosphere.

3. *On Lightning Conductors.*

Lightning conductors.

We have already seen that electricity is from various causes generated and set free in our atmosphere, and that individual clouds and masses of clouds are often highly charged with electricity, and insulated by the surrounding air. The earth and the sea are good conductors of electricity; and, generally speaking, their natural electricity is undisturbed. The attraction, therefore, of the electricity of the clouds for the opposite electricity in the earth or the sea, may become so powerful as to break through the resisting medium which intervenes. If the clouds are above a mountain or rising ground, this discharge of electric matter into the earth is attended with no danger. The effects have sometimes been traced in the fusion of portions of the rocks which crown these exposed summits. If a tree stands in the stratum of air through which the cloud discharges itself, the lightning passes through it, cleaving it, dissipating its sap into a visible vapour, and sometimes splitting the lower part of it into fibres like lucifer matches. If a house obstructs its path, the electricity descends through its walls, seeking the quickest and easiest passage to the earth. It will follow bell-wires, iron rods, damp walls, and gilded pictures, and find out any matter, whether organized or unorganized, living or dead, which is placed near its path and is capable of advancing it on its rapid and breathless errand to the earth. If a living animal grazing, or a human being walking, in an open field, intervenes between the overcharged cloud and the ground, the one or the other will become the chosen path of this irresistible foe. If a ship floats under an electrified canopy of vapour, it has less chance of escape than the tree, the house, or the living being.

The only terms upon which we can meet this relentless enemy, is a humble admission of its supreme and irresistible power, and a resolution to give it the freest and the fullest passport. We must supply it, in short, with a railway of metal, the only species of road upon which it can travel with a suitable speed, and a harmless intention. The moment it ceases to find a conducting body, it begins its devastation among imperfect or non-conducting substances, till it again gets into a safe and easy path.

The common practice of using cylindrical rods of copper or iron for conducting the lightning to the ground affords to buildings a very imperfect security. It has been supposed that such rods would influence the discharge from a cloud at a distance equal to two-thirds of the height of the rod, and therefore give protection to that extent. This, however, is not the case, for buildings have been often struck in one place when there was a conductor not very far from the spot that was struck; and, in the case of ships, the foremast has been frequently struck when a lightning chain was applied at the mainmast.

Lightning conductors for buildings.

In securing buildings, one or more capacious channels of conduction should be applied systematically to certain parts of them along the walls, terminating above in solid projecting points, and below by two or more branches under the surface of the earth. These main channels should consist of the best metallic conductors. Copper is to be preferred, and they may either consist of stout copper tubing, from an inch to 2 inches in diameter, and not less than $\frac{1}{8}$th of an inch in thickness; or otherwise, of copper plates, varying from 2 to 4 inches in width, and of a similar thickness. These may be carried down either within or without the building, as circumstances may require. When copper tubing is employed, the joints must be well secured over solid plugs by screw joints, and be firmly pinned to them. When plates are used, it would be desirable to place them in two layers, one over the other, so as to admit of the continuous portions of the one covering the joints of the other. The plates should be firmly united at the joints, and should be $\frac{1}{8}$th to $\frac{1}{16}$th of an inch in thickness. These lines of conduction should be secured immediately against the masonry, and not be placed at any distance from the building, or pass through rings of glass or other insulators, as is sometimes erroneously done. It is to be here remembered, that the materials of which a building consist are already conductors of electricity to a very considerable extent, and will of themselves allow large quantities of atmospheric electricity a fair passage to the earth. The object in applying metals along the walls is to complete the conducting power of the general mass up to the point required for a full transmission of a shock of lightning without intermediate explosion, and therefore the closer the conductor is applied to the walls the better. The notion of keeping the electrical discharge out of the building by insulating the conductor from its walls is evidently very futile, and can only arise out of a false view of the nature of the electrical discharge, which (as we have already seen experimentally) is determined to the surface of the earth in a path of least resistance, which the conductor itself supplies. We can not therefore imagine that the electrical agency will leave a good capacious conductor, immediately in its line of action, and in which the resistance is a minimum, to move in a bad conducting circuit out of that line, in which the resistance is a maximum. But if we were to admit that such an effect were possible, even then it is not to be supposed that a small mass of bad conducting matter, such as a small ring of glass or a little pitch, could arrest such a terrible agency in its onward course. An agency which can shiver immense oak trees, split solid rocks asunder, and break down half a mile thick of air, would scarcely be arrested by an insignificant mass of glass or pitch. It has been the custom in some instances to place balls of glass on the pinnacles of towers and on the masts of ships, under the impression that glass is a repeller of lightning, but it is evident that glass is no more a repeller of lightning than the air itself. The spire of Christ Church at Doncaster had a ball of glass placed on it, with a view to its security from lightning. In November 1836, however, it was struck by the electrical discharge, and the spire totally destroyed.[1]

The main conducting channels being complete to the earth and applied in selected positions in the way alluded to, we should be careful to link into connection with them, so far as possible, all the vicinal detached masses of metal in the building, either by branches or immediate contact; and in this way bring the general mass into that passive electrical state it would have as regards the electrical discharge, supposing the whole structure were metallic throughout, or at least as nearly as may be, so that in case of lightning striking with fury on any point of the building, the explosive action may vanish, and the discharge have unlimited room for expansion in all directions upon the surface of the earth to which it is always determined.

Lightning conductor for ships.

The necessity of providing against the destructive agency of lightning on ship board has been long felt. The continuous and fixed metallic conductors available for build-

[1] *Times* Newspaper, 7th March 1836.

Electrical Apparatus.

ings were not however equally applicable in ships, in consequence of the masts, the only parts to which they could be well attached, being subject to motion in a variety of ways, to frequent elongation and contraction, and to the necessity which frequently arises for removing the higher portions of the mast altogether. It was hence proposed to substitute long flexible chains, or links of copper about the size of a goose quill. These being supplied to ships packed in boxes, were hoisted up to the truck as occasion required, were stepped along the rigging, and allowed to hang overboard in the sea. Of late years copper wire rope has been somewhat extensively applied in this way as rigging, and there is little doubt but that these temporary forms of lightning conductors for ships may occasionally transmit very heavy shocks of lightning. Unfortunately, however, the many trying and variable circumstances under which a ship is placed—the liability of damage to the ropes and rigging, and the complication of changes to which the whole is subject, has, generally speaking, baffled all these attempts to secure ships against the electrical discharge; so that notwithstanding that ships have been commonly supplied with such lines of conduction, the amount of destruction in the royal navy and in the merchant service has been very frightful, as appears by parliamentary papers, printed by the House of Commons in December 1854. Hence the necessity of some more capacious and permanent security, and which from time to time has been repeatedly called for. Mr Singer, in his excellent work on electricity, suggested the possibility of joining continuous rods applied to the masts by flexible spiral wires, observing at the same time, "that the conductors employed to protect ships from lightning are by no means so efficient as requisite, that they are kept packed in boxes, so that, partly from inattention, and partly from prejudice, they frequently remain in the ship's hold unemployed altogether." But besides these mechanical objections, such temporary forms of conductors are not always secure on account of their small capacity. The Hotel des Invalides at Paris, having a conductor of twisted wire ropes was struck by lightning in June 1839, the wire was knocked in pieces and the building damaged.[1] The same thing happened in H. M. ship "Hazard," struck by lightning at Sarawak, Borneo, in June 1846. This vessel had a conductor of copper wire rope—the wires were twisted in pieces, torn from the ship's side; the electrical discharge divided between the main-mast and rope, a portion of it shivered the spars, and went into the hull. The commission appointed by the Board of Admiralty in 1838 under the countenance of the House of Commons, to inquire and report on the best form of lightning conductors for H. M. ships gave, in their report, many examples of the insufficiency of temporary conductors applied as rigging, to meet the exigencies of the case, and concurred fully in the opinion advanced by every practical seaman, that if lightning conductors be applied on shipboard, they should be applied under a capacious and permanent form, so as to render them secure and independent of the officers and crew of the ship.

Sir W. Snow Harris's inquiries.

About the year 1820, Sir W. Snow Harris having devoted himself to the investigation of the best means of guarding the royal navy from lightning, and the general laws of atmospheric electrical discharge, proposed to the Board of Admiralty a new method of capacious electrical conductors for ships, to be permanently fixed and systematically applied along the masts, and generally throughout the hull, so as to render the vessel secure from lightning at all times and under all circumstances, without the officers and crew of the ship incurring any responsibility whatever for due attention to their application or care in handling them under various trying circumstances, as in the case of the ordinary chains, and not unfrequently to their great peril and annoyance. Adopting the broad general principles we have already laid down as the true theoretical ones for lightning conductors, the inventor came to the conclusion that if a ship were perfectly conducting in all its structure, no damage could arise to it when struck by lightning; since at the instant of the electrical discharge falling on any point aloft, the explosive action would vanish, and would be converted into a comparatively quiescent current action with unlimited room of expansion upon the surface of the sea in all directions, that is upon one of the surfaces to which the discharge is determined.

Sir W. Snow Harris's ship-conductors.

In order to afford a ship effectual protection from lightning, Sir W. Snow Harris conceived it to be essential that the conductor be as continuous and direct as possible from the highest points to the sea; that they be permanently fixed in the masts throughout their whole extent, so as to allow one part of the mast to move upon another; and, if any part of the mast should be accidentally or wilfully removed along with the conductor attached to it, that the remaining portion of the conductor should still be perfect, and capable of transmitting an electrical discharge into the sea. To accomplish these objects, a sort of double conductor should be formed, consisting of two laminæ of sheet copper, placed one above the other, so that the extremities of the laminæ of one layer should be opposite the middle of the laminæ of the other layer. These laminæ are each about four feet long, from six inches to one and a half broad; the thickness of the under layer being one eighth, and of the upper layer one sixteenth, of an inch. The copper bands thus formed are fixed in a fine dove-tailed groove in the aft sides of the different masts, and are secured in their place by wrought copper nails, so as to form a smooth surface, the nails being driven at each side, so as to be about four inches apart. Before inserting the conductor, the groove should be painted over with white lead, and must be deep enough to allow the copper to lie a little beneath the surface of the wood. "The metallic line," says Sir S. Harris, "thus constructed, will then pass downward from the copper spindle at the mast-head, along the aft sides of the royal-mast and top-gallant-mast, being connected in its course with the copper about the sheeve-holes. A copper lining in the aft side of the cap through which the top-mast slides now takes up the connection, and continues it over the cap to the aft side of the top-mast, and so on as before, to the step of the mast; here it meets a thick wide copper lining, turned round the step, under the heel of the mast, and resting on a similar layer of copper fixed to the keelson; this last is connected with some of the keelson bolts, and with three perpendicular bolts of copper, of two inches diameter, which are driven into the main keel upon three transverse or horizontal bolts, brought into immediate contact with the copper expanded over the bottom. The laminæ of copper are turned over the respective mast-heads, and secured about an inch or more down on the opposite side; the cap which corresponds is prepared in a somewhat similar way, the copper being continued from the lining in the aft part of the round hole over the cap, into the fore part of the square one, when it is turned down and secured as before, so that when the cap is in its place the contact is complete. In this way we have, under all circumstances, a continuous metallic line from the highest points to the sea, which will transmit the electric matter directly through the keel, being the line of least resistance."[2]

[1] *Comptes Rendus*, 1839.

[2] "Since the mizen-mast does not step on the keelson, it will be necessary to have a metallic communication at the step of the mast, with the perpendicular stancheon immediately under, and so on to the keelson as before, or otherwise carry the conductor out at the sides of the vessel."

Electrical Apparatus.

This metallic line is shown in Plate CCXXVII., figs. 14, 15, 16, by the dotted line ABCD; and it will be seen that any elongation or contraction of the masts, as in figs. 14 and 15, or the removal of either of them, as in fig. 16, which brings them into a new position, will in no way disturb the continuity of the line ABCD, which evidently remains the same, and is therefore, under these different circumstances, the shortest and best conducting line between the mast-head at D and the sea at S. When the sliding masts are struck, a part of the conducting line necessarily remains below the cap and top; but as this is quite out of the circuit, it will not at all influence the passage of the electric fluid along the shorter line. For this invention Sir William Snow Harris has received from the government the sum of L.5000, a very inadequate reward for so great a service.[1]

Plate CCXXVII., figs. 14, 15, 16.

CHAP. II.—DESCRIPTION OF INSTRUMENTS FOR ACCUMULATING, CONDENSING, AND MULTIPLYING ELECTRICITY.

Instruments for accumulating electricity.

The instruments which have been employed for the purposes of accumulating, condensing, doubling, and multiplying electricity, may be divided into four classes:

1. Jars and batteries.
2. Condensers.
3. Doublers.
4. Multipliers.

SECT. I.—*On the Construction and Action of Jars and Batteries.*

Jars and batteries.

By means of the prime conductor of an excited electrical machine, we can obtain electricity in sufficient quantity and intensity for many important researches; but when we wish to accumulate it in great quantities, and to obtain a powerful charge, it is necessary to employ the Leyden phial or jar; and by increasing the number of jars, and uniting them together, we can accumulate electricity to an unlimited extent.

Electrical jar.

An electrical jar, in its best form, is shown in Plate CCXXVIII., fig. 1, where AB is a glass jar having its lower end CDEB coated both on the outside and the inside with tinfoil, which is made to adhere to the glass by means of gum water. The jar should have no cover, as it generally has, and the charge should be conveyed to the bottom of the jar by a copper tube FGH, three eighths of an inch in diameter. This tube terminates in a ball, F, of baked wood, and is kept in its place by a convenient foot, firmly cemented to the bottom of the jar, which is previously covered with a circle of pasted paper, leaving a central portion of the coating free for the perfect contact of the charging rod FGH, which passes through the centre of the foot, as shown by the dotted lines in the figure.[2] When the jars are either employed singly, or united so as to form a battery, they should be placed on a conducting base, supported by short columns of glass, or some other insulating substance, such as rosin or brimstone, so that the whole can be insulated when necessary.

Fig. 2.

In order to allow the jars to be charged and discharged with precision, Sir W. Snow Harris connects them with what he calls two centres of action, A, B, shown in fig. 2. The first of these, A, consists of a brass ball, which slides with friction on a metallic rod AD, so as to admit of its being placed at any required height. This ball has a number of holes perforated in its circumference, to receive the points of the rod or rods which connect it with the jar or jars. The rod AB which supports this ball may be either insulated on a separate foot, and connected with the prime conductor, or it may be inserted directly into it. The second centre of action consists of a larger ball of metal, B, attached to a firm foot, and placed on the same conducting base with the jar, so as to be perfectly connected with it. When the first centre of action, A, requires to have a separate insulation, the insulating glass rod is screwed immediately into the lower ball B, and sustains the metallic rod above described, by the intervention of a ball of baked wood, D, the opposite end of the rod terminating in a similar ball, C, through the substance of which the conducting communication with the machine passes when it is placed on a separate foot. All the metallic connection should be covered with sealing-wax, except at the points of junction, and the wooden balls and different insulations should be carefully varnished.

Electrical battery, fig. 3.

A battery constructed in this manner, and containing six jars, is shown in fig. 3, A and B being the two centres of action, and C and D the two balls of baked wood, as shown in fig. 2. The communication with the prime conductor is made by a wire CE passing through the ball C, and the jars communicate with the centre of action A by means of wires entering the ball A, as shown in the figure.

In order to charge the jar shown in fig. 1, it is only necessary to make the copper tube FG communicate with the prime conductor of the electrifying machine by means of a wire passing through F. It was formerly the custom to make the copper rod HG terminate above in a brass ball at F; and when this was the case the jar could be charged by bringing the ball F near the conductor, or by holding the jar by the outside coating, and bringing the brass knob close to the conductor.

When the jar is fully charged, it may be discharged by holding the outside coating in one hand, and touching with the other the copper tube FG, or the ball F if it is a brass one; but in this case the person will receive a shock, the electrical charge passing into his body. The jar may be discharged without receiving a shock, by a very simple instrument called a *discharging rod*, shown in fig. 4. It consists of two bent wires BC, BD, having a brass ball C and D at each end, and uniting at B, where they are fastened at their common junction into a glass handle AB. The operator takes hold of the glass handle, and placing the lower knob D on the outside coating of the jar, and the upper knob C in contact with the copper wire FG, or the brass ball at F, if there is one, the discharge takes place with a loud snap the instant that the knob C touches F.

Discharging rod, fig. 4.

Fig. 5.

A more convenient form of discharging rod is shown in fig. 5, where the two balls C, D, and the branches CE, DE, correspond to the balls C, D of the branches CB, DB, in fig. 4; but in place of attaching one insulating glass handle to the joint E, a separate glass handle, viz. A and B, is attached to each branch. By this means, by taking the handle A in one hand, and B in the other, we can open the balls C, D to the required distance without touching the metallic branches CE, DE, and also with greater facility and certainty.

If the jar is connected with the piece of apparatus BC, fig. 2, so that the centre of action A communicates with the internal coating of the jar, and the centre of action B with the external coating, then the jar will be discharged by making the knob D of the discharging rod touch B, while the knob C touches A. In like manner the whole battery in fig. 3 may be discharged by making the knob D of the discharging rod touch B, while the knob C touches A.

Henley's universal discharge. Plate CCXXVIII. fig. 6.

A general instrument for discharging jars and batteries, invented by Mr Henley, has been much used, particularly in the deflagration of metals by electricity. It is shown in fig. 6, where A and B are insulating glass pillars, cemented into a wooden stand. A brass cap with a horizontal and vertical motion is fixed on the top of each of these pillars;

[1] See the *Edinburgh Review*, Oct. 1844, vol. lxxxi. p. 442.

[2] The method of constructing the jars and batteries here described is that used by Sir William Snow Harris, and described in his valuable paper on the Laws of Electrical Accumulations.

and at the top of this joint is a spring tube, through which the handles D or C can be slid backwards or forwards. These handles are made of strong brass wire, terminating at one end in a ball, or point, or a pair of forceps, and at the other in a solid glass rod for an insulating handle. A small wooden table F, about five inches in diameter, has a slip of ivory glued into its upper surface, and may be raised or depressed in its socket by the screw-nut G. Sometimes a small mahogany press accompanies the instrument. It consists of two boards, which can be pressed together by two nuts, and is put into the socket in place of the table F, when it is necessary to fix or hold steady the body through which the discharge is to be passed. The body to receive the charge must either be laid on the table or fixed in the press, or held between the balls, points, or forceps. The two sides of the jar or battery are then connected with the two brass caps at the tops of the pillars A, B; and, by means of the insulating handles, the distance is regulated through which the charge has to pass.

This instrument was originally constructed without any insulating handles; and the wires, and the handles C and D, were thick brass wires, terminating on one side in a ball or point, and on the other in a ring of brass, with which the connection with the jar or battery was formed.

Coated plates of glass.

Although it has proved advantageous to use jars for receiving and accumulating electricity, yet this form of the recipient is by no means essential. The very same effect is obtained if a plate of glass is coated on both sides within an inch of its edges; for a jar may be considered as a plate of glass rolled up into a cylindrical form. Hence a battery may be composed of a number of coated plates of glass; and it was actually with one of this kind, consisting of eleven panes of window glass, that Dr Franklin performed most of his experiments.

When one of these panes of glass is fitted up as in the annexed figure, it is called the *sparkling pane*, or the *magic picture*, and is a good illustration of the Leyden jar. A sheet of tinfoil, TT, is attached to its two surfaces, leaving a space of two or three inches between the edges of the tinfoil and the edges of the plate of glass, both fixed in a frame. When one of the sheets is electrified, and the other is put in communication with the ground, a bright spark is obtained by making the two sheets communicate by means of a discharging rod. A Leyden jar or phial is therefore nothing more than a pane turned into a cylinder, the coating on the inside of the jar representing one side of the pane, and the outside coating the other.

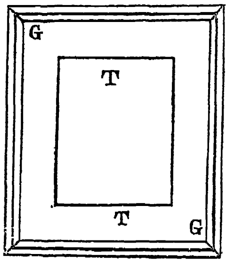

Fig. 12.

If, instead of the sheets of tinfoil, we cover the space which they occupy with metal filings stuck upon the glass by gum, and electrify one side as before, the discharge produced by the discharging rod will produce an infinite number of brilliant sparks passing from each metallic particle to its neighbours, and occasioning the sparkling from which the name is derived.

Franklin's theory of the Leyden phial.

Dr Franklin was the first person who explained the principle upon which the action of the Leyden jar depends. He began by examining the electricities of the inside and outside coatings. A cork ball suspended by a silk thread was attracted by the outside and repelled by the inside coating. When the jar was charged with the opposite electricity, the ball was repelled by the outside and attracted by the inside coating. Hence it follows that *the outside and inside coatings of a Leyden jar are charged with opposite electricities.*

When the inside coating was charged from the prime conductor, its electricity was positive, while that of the outside was negative; but when the outside of the jar was charged from the same conductor, the outside was positively electrified, and the inside negatively, and the charge was as strong as before.

In order to show that the negative electricity of the one coating was equal to the positive electricity of the other, Dr Franklin hung a small linen thread near the outside coating of a charged jar, and every time that he touched the knob or wire of the jar the thread was attracted by the coating, the electricity taken from the inside by the finger being equal to what was drawn in on the outside by the thread. He then repeated this experiment when the jar was placed upon an insulating stand, and he found that at every successive contact a portion of the electricity of the outside became free, and the linen thread sprang to the outside coating to receive and carry off the superfluous electricity.

Richman's experiment to show the equality of the two electricities. Plate CCXXVIII. fig. 7.

The equality of the two electricities is still more clearly evinced in the fine experiment of Professor Richman, shown in fig. 7. Having coated with tinfoil the opposite sides of a plate of glass AB, to within two inches of its edges, the glass was then placed vertically, and a linen thread *m* was suspended to the upper part of each of the two coatings. When the plate was not charged, the two threads hung down parallel to each other, and touched the tinfoil; but when the plate of glass was charged, the threads were repelled from the glass, and formed equal angles with it on both sides. When any conducting body, such as the finger, was brought near one coating, the thread on that side sunk, and formed a less angle with the glass, while the thread on the other side rose to a greater angle, the augmentation of the angle on one side being exactly equal to its diminution on the other. When the finger touched one coating, the corresponding thread fell down entirely, and the thread on the other side rose to a double elevation, so that the angle formed by the two threads was a constant quantity, depending on the intensity of the charge communicated to the plate.

Franklin's experiments. Fig. 1.

The next point of inquiry to which Dr Franklin applied himself, was to ascertain where the two electricities resided, and what was the function performed by each coating. Having charged a jar, and placed it on an insulating stand, he took out the ball F, and rod FH, fig. 1, and found that they did not contain any electricity. He then touched the outside coating with one hand, and putting the finger of another hand into the mouth of the bottle, he received a shock as powerful as if the ball and rod FH had been in their place. He next put into the phial some clean water, which, being a conductor, answers the same purpose as tinfoil, and having charged the jar, and poured out the water into an insulated bottle, he found that it would not give the shock. Upon filling the phial with fresh water, and without giving any new charge to the jar, he received a shock as at first, which clearly proved to him that the electricity resided in the glass. This important truth may be clearly established in the following manner:—Take a cylindrical jar, and let the outside and inside coatings of tinfoil be nicely fitted, and applied to the surface without any cement. When this jar is charged in the usual manner, place it on an insulating stand or a glass plate, and holding it by the uncovered part, lift out the interior cylinder of tinfoil without injuring its shape, and then lift the glass cylinder out of its exterior coating. If we now touch the outside of the glass cylinder with one hand, and at the same time the inside with the other, we shall obtain no perceptible shock. In like manner, no shock will be experienced by touching the outside coating of tinfoil with one hand, and the inside with the other, nor by touching either separately. But if the two coatings are again replaced on the glass cylinder, the one on the outside and the other on the inside, a shock will be obtained in the usual way. Hence it follows, as Dr Franklin concluded from the same experiment in another

Electrical Apparatus.

form, that the electricity is accumulated on the surface of the glass, and that the metallic coatings, or other conducting substances, which are placed in contact with both sides of the glass, perform only the function of forming a perfect communication between every point of the external with every point of the internal surface of the glass at the instant of the discharge.

Theory of the Leyden jar. Plate CCXXVIII. fig. 8.

In order to explain the theory of the Leyden jar, let us place a jar AB uncharged upon an insulating stand, and make its outside coating B communicate with a pair of insulated pith balls m, n, as shown in fig. 8. From the prime conductor convey a few sparks of positive electricity to the jar by the knob F, the pith balls m, n will diverge with positive electricity, owing to the decomposition of the natural electricity of the external coating. If we now touch the pith balls, the positive electricity which made them diverge will escape, and they will fall into their natural vertical position. But we have not thus removed all the positive electricity which was communicated to the interior coating. A portion of it has become *fixed* or *latent*, or *disguised* or *dissimulated*, which can only happen from the influence of a portion of resinous electricity. If we now touch, indeed, the brass ball F, the portion of positive electricity which remains free in the inside coating will cause the pith balls communicating with the outside coating to diverge with negative electricity.

Disguised electricity.

If, when the pith balls are divergent with positive electricity supplied from the conductor, we touch them so as to allow it to escape, the repulsive force which it exerted on that in the interior coating will cease, and the ball F and the interior coating will be capable of receiving an additional quantity from the conductor. The pith balls will again diverge with positive electricity; and if this be removed, the ball F will again be able to receive a farther supply from the conductor, so as to make the pith balls again diverge. The interior coating will be receiving more and more positive electricity, till its repulsive power becomes so great as to resist the introduction of any more. The jar is now charged, and will give a shock in the usual manner, or may be discharged by the discharging rod. Hence we may conclude that the positive electricity introduced into the inside coating of the jar decomposes the natural electricities of the outside, drives away from it the positive and fixes the negative electricity, which, by its reciprocal attraction, fixes also a part of it in its turn.

Plate CCXXVIII. fig. 9.

From the principles above established, it may be shown that a given quantity of electricity from the prime conductor may be made to charge two or more jars, almost as powerfully as if the whole quantity was communicated to one jar only. The jars being placed as in fig. 9, the electricity from the prime conductor is conveyed by a chain A to the ball B of the first jar. The ball F of the second jar has a similar connection with the coating of the first, and by a third chain the coating of the second jar is connected with the earth. When the inner coating of the first jar receives positive electricity, the outer coating has its natural electricity decomposed; the negative portion is fixed by the influence of the positive electricity within, and the positive portion is repelled to the interior of the second jar, where it does the very same thing which was done by the same electricity within the first jar. The positive electricity set free at the exterior of the second jar is repelled to the earth, and any requisite portion of negative electricity is conveyed to the outer coating of the same jar, in order to fix by its influence the positive electricity which arrives at the interior of the jar. If we now remove all the connections, the two jars will have received their full charge; and the same will take place with any number of jars similarly arranged for the purpose.

As the accumulation of electricity in a jar depends upon the mutual attraction of the two electricities, and as this force varies inversely as the square of the distance of the molecules, the intensity of charge which any jar can receive should increase with the thinness of the glass which separates the two fluids. Mr Cavendish inferred from his researches, that the intensity of the charge was inversely as the thickness of the glass; but we cannot avail ourselves of this principle in practice, as a certain thickness of glass is necessary to the due strength of the jar; and it has been proved by experiment, that when the glass is thin, the mutual attraction of the two electricities has been capable of forcing a passage through the glass itself. The common glass jars, therefore, are as thin as they can be made with perfect safety. Mr Brooke always placed a layer of paper between the tinfoil and the glass, for the purpose of enabling the jar to contain a charge of greater intensity.

An insulated wire in water a Leyden jar.

A very remarkable apparatus, similar to a Leyden jar, is made by a long wire insulated with gutta percha, and placed in water. We owe this beautiful experiment to Dr Faraday, who made it with a wire 140 miles long, one end of which communicated with a pile of 360 elements of zinc and copper, charged with acidulated water. The pile was perfectly insulated, and communicated with the ground by its second extremity. The insulation of the wire was so perfect that the remaining current produced only a deviation of 5° in the galvanometer. When the communication of the pile with the long wire was cut off, the following phenomena were observed. Upon touching with the finger either extremity of the long wire, a powerful sensation was felt, which was repeated after a great number of successive touches of the finger. The sensation was felt even after an interval of five minutes. If, instead of discharging the electricity with the finger, the wire is connected with a galvanometer, a very great deviation is produced, and is still perceptible half an hour after the pile is removed from the wire. All this is easily explained. *The wire is a Leyden phial!* The copper wire is the inside coating, the gutta percha is the glass, and the water the external coating; and when one end of the wire communicates with a source of electricity, it becomes charged. When the wire is placed in air the phenomena disappear. In one of Mr Faraday's experiments the wire was 1·6 millimetre in diameter, and the insulating layer of gutta percha 2·5 millimetres. Hence the interior coating of this species of Leyden jar had a surface of nearly 770 square metres, and the exterior coating a surface of 3050 square metres.

Cavallo's self-charging jar.

Before concluding this section, we shall describe a pretty little instrument invented by M. Cavallo, called the *self-charging* jar. Having procured a glass tube eighteen inches long and one and a half inch in diameter, coat one half of the inside of it with tinfoil, and close the aperture of the coated end with a cork, through which there passes a wire touching the inner coating, and terminating in a brass ball fixed at the uncoated end of the tube. If we now hold the uncoated part of the tube in one hand, and rub the outside of the coated part with the other, and after every three or four strokes touch with the rubbing hand the brass knob or ball, the hand will communicate to it a spark, and the inside coating will thus be gradually charged. If we now grasp the outside of the coated end with one hand, and with the other touch the brass ball, we shall discharge the tube and receive a shock.

The lateral explosion.

If we insulate a metallic tubular or solid rod rounded at the extremities, and about an inch or less in diameter, and place it against the external coating of a charged jar, and then place another metallic cylinder of five or six feet long within about half an inch of its opposite extremity, it will be found that at the instant of discharging the jar by means of a common discharging rod and a chain resting on the table near the outside of the jar, a small spark will be ob-

Electrical Apparatus.

served to pass between the insulated conductor, touching the outer coating of the jar, and the conductor near its opposite extremity. Or if we connect a piece of metallic chain any how with the outer coating, and discharge the jar through another circuit independent of the chain, then at the instant of the discharge the links of the chain will appear luminous, showing that some kind of electrical action has been produced in it. This phenomenon has been called "Lateral Explosion," and as it has been sometimes associated with the passage of lightning along lightning conductors, it will be requisite to see in what this kind of electrical action consists. The most critical analysis as yet made of this phenomenon appears in a paper by Sir Snow Harris in the London and Edinburgh Philosophical Magazine for December 1839, to which we must refer the reader.

Sect. II.—*On the Construction of Condensers of Electricity.*

Condensers of electricity. Plate CCXXVIII. fig. 10.

An apparatus for condensing electricity in a conducting body was the undoubted invention of M. Æpinus, who also gave the true theory of its action. Volta, however, had the merit of first applying it to an electrometer for indicating small quantities of electricity.

The condenser shown in fig. 10 consists of two separate parts, the first of which is a metallic disc B, supported by a metallic stand BD, and the second is a similar disc A, having a glass handle C rising from its tube, and a small metallic pin and knob P projecting from its circumference. The upper surface of the plate B and the lower surface of A are covered with a thin film of a non-conducting substance, such as varnished silk, rosin, or glass. If it is now wished to condense any feeble electricity from any body, as, for example, from a feebly electrified conductor, bring the metallic pin P into contact with the body or electrified conductor; and while it is in contact let the metallic disc B be brought close under it, as in the figure, the varnished surface of A resting on the varnished surface of B. In this state withdraw the whole from the prime conductor; and having removed the plate B, apply the plate A to two suspended pith balls, which will separate to a very considerable angle in consequence of the electricity having been condensed by the contact of the disc B. That this is the case may be readily proved by applying A to the pith ball before the disc B was joined to A, when their divergence will be greatly less than before. The explanation of this is very simple. The positive electricity, for example, conveyed by the prime conductor to the plate A decomposes the natural electricity of B. The positive portion of B is repelled to the earth by the similar electricity in A, while the negative portion is attracted to the upper surface of B by the opposite electricity in A. In this position it is capable of attracting to the inner surface of A an additional quantity of the free electricity in the prime conductor; and this additional quantity will in its new position produce a farther decomposition of the natural electricity of C. All these effects will take place simultaneously till an equilibrium is established between the free positive electricity supplied to A by the prime conductor, and the negative electricity which the attractive force of this electricity can draw from the earth.

It is manifest, from these observations, that the principle of the condenser is exactly the same as that of the Leyden jar. The upper disc A which receives the electricity corresponds with the inner coating of the jar, the under disc C with the outer coating, and the film or films of rosin, &c. with the glass of the jar.

Volta's condensing electrometer, fig. 11.

The condensing electrometer of Volta is shown in fig. 11, where CAB is the condenser above described. From the lower side of the plate B are suspended, by two metallic wires, two perfectly even and straight straws m, n, and on the mouth of the bottle DEFG is fixed the disc B, so that the two straws hang freely in the axis of the neck of the bottle. A graduated circle seen below mn is pasted on the outside of the bottle, to estimate the angular separation of the straws, which affords a mean of the electricity condensed in the manner already described.

Cuthbertson's condenser, fig. 12.

Mr Cuthbertson's condenser, shown in fig. 12, consists of two flat circular plates of brass, A, B, about six inches in diameter. The receiving plate A is supported by a glass pillar, firmly fixed to a wooden stand, while the condensing plate B is sustained by a brass pillar, but so as to move round a joint at its lower end, in order that it may be thrown back into the dotted position shown in the figure. When the plates stand parallel and vertical, the receiving one A is connected by a wire with the body whose electricity is to be condensed. In this state it is allowed to continue for a short time, when the wire is removed and the plate B thrown back into the dotted position. The electricity will then be found condensed in the plate A.

Fig. 13.

When this instrument is applied to an electrometer, as in fig. 13, it forms an excellent condensing electrometer; and the effect may be greatly increased by uniting Cuthbertson's condenser with that shown in fig. 13. This may be done by merely uniting the moveable plate of the former to the fixed plate A of the latter by a small brass pin.

Nicholson's spinning condenser, fig. 14.

Nicholson's spinning condenser, which is a very ingenious instrument, is shown in fig. 14, where A is a metallic vase, which revolves about a steel axis EK, whose pivot K runs in the adjustable socket C at the bottom of the stand H. A circular disc of glass D, one and a half inch in diameter and two-tenths thick, is fixed to the vase A, and revolves along with it, while a similar plate E is fixed on the top of the stand H. These two discs are shown separately in fig. 15. In the edge of the plate E are drilled two holes to receive metallic hooks F, G, and into the edge of the upper plate D are cemented two small tails of the flattened wire used in making silver lace. These tails are bent down so as to strike the hooks F, G during their revolution, without touching the rest of the apparatus. The two adjacent faces of the glass discs are coated with segments of tinfoil, as shown in fig. 15; and they may be set at any distance by means of the screw C. Each tail communicates with the tinfoil coating of D; the hook F communicates with that of E, but the hook G is insulated so as to communicate only with the electrified body. The coating of E communicates with the earth by means of the stand H.

Fig. 15.

If the vase A, the plate D, and the axis EK, are now set a spinning by the action of the finger and thumb applied at T, one of the tails will strike the hook G, and receive through it from the electrified body some of its electricity, which it will convey to D, which will thus assume the electric state of the body. The tail which has struck G proceeding onwards, will after half a revolution touch F, and will convey the free electricity received at G to the two coatings, which with the hook F constitute one insulated mass. The tail advances, acquires more electricity from G, deposits it at F, and thus condenses it, on the principle of the common condenser, till it is capable of affecting the pith balls at F. The instrument constructed by Mr Nicholson was five inches high, and condensed very small degrees of electricity.

Sect. III.—*On the Construction of Electrical Doublers.*

Electrical doublers.

This class of instruments operate by continually doubling small quantities of electricity till the common electrometer is capable of indicating its presence and qualities.

Bennet's doubler.

The doubler invented by Mr Bennet consists of three plates, A, B, and C, fig. 16. The plate A, which is of brass,

Electrical Apparatus.

has an insulating handle rising from its centre; the plate B, which is also of brass, has a similar handle fixed in its circumference. The third plate, C, also of brass, is placed on Bennet's gold-leaf electrometer. The under side of A, the upper side of C, and both sides of B, are varnished. The body whose electricity it is required to double is brought into contact with the under side of C, which rests on the cap of the electrometer, while B is touched with the finger of the other hand. The communication with the electrified body being broken off, B is lifted up by its glass handle. If the electrometer leaves do not diverge, A is placed by its handle upon B, thus lifted up; and A being now touched by stretching a finger over the juncture of its insulating handle and immediately withdrawing it, A is separated from B. In this situation two of the plates have obviously nearly equal quantities of one kind of electricity, while the third plate has the opposite kind. The plate A is then made to touch the under surface of C, resting on the electrometer, and at the same time C is covered with B. The plate B is now touched by the finger as A was; and removing A, and withdrawing the finger from B, and lifting it up from C, the electricity is doubled. By repeating this operation ten or twenty times, which may be done in forty seconds, the electricity will, by continual duplication, be augmented 500,000 times When sparks are required, C must rest on an insulating stand in place of the electrometer.

Bennet's doubler. Plate CCXXVIII. fig. 16.

It was found by Mr Bennet, Cavallo, and others, that the doubler became strongly electrified even when no electricity was communicated to it. To remove this evil, M. Cavallo used three plates without varnish, and he placed them on insulating stands, so as to have a vertical direction, and to stand within one-eighth of an inch of each other, the plates of air being a substitute for the varnish. The method of doubling is exactly the same as before. Dr Robison adopted the same idea, but he kept his plates horizontal, making them rest on each other by three small spherules of glass or sealing-wax. Notwithstanding these precautions, however, electricity was still produced.

In order to perform the operation of doubling with more rapidity, Dr Darwin proposed the *moveable doubler*, or one in which the plates could be moved by wheel-work into their proper positions. Dr Nicholson improved upon this idea by producing the whole effect with the simple revolution of a winch.

Nicholson's revolving doubler. Plate CCXXVIII. fig. 17.

This *revolving doubler*, as it has been called, is represented in fig. 17. It consists of two fixed plates of brass A, C, two inches in diameter, insulated separately, and placed in the same plane, so that a revolving plate B may pass near them without touching. A brass ball D is fixed on the end of the axis which carries B, and is loaded within at one side so as to counterpoise the plate B, and allow it to rest in any position. The axis PN, and the axes that join the three plates with the brass axis NO, which passes through the brass piece M, by which the plates A and C are supported, are made of varnished glass. One end of this axis carries the ball D, and the other is connected with a rod of glass NP, upon which the handle L is fixed, and also the piece GH insulated separately. The pins E, F rise from the back of the plates A, C, at equal distances from the axis. The arm K is parallel to GH, and the ends of both are armed with pieces of harpsichord wire, so as to touch the pins E, F in certain points of their revolution. A pin I is fixed on M to intercept a small wire proceeding from the revolving plate B. These wires are so bent that, when B is opposite to D, GH connects the two fixed plates, A, C, while the wire and pin at I connect the ball D and plate B. On the other hand, when B is opposite C, D is connected with C by the contact of F with the wire at K, the plates A, B being then entirely unconnected with any other part of the instrument. In all other positions the three plates and the ball D will have no connection with each other. The operation of this instrument is thus described by Mr Nicholson: "When the plates A and B are opposite to each other, the two fixed plates A and C may be considered as one mass, and the revolving plate B, together with the ball D, will constitute another mass. All the experiments yet made concur to prove that these two masses will not possess the same electric state; but that, with respect to each other, their electricities will be *plus* and *minus*. These plates would be simple, and without any compensation, if the masses were remote from each other; but as that is not the case, a part of the redundant electricity will take the form of a charge in the opposed plates A and B. From other experiments, I find that the effect of the compensation on plates opposed to each other at the distance of one-fortieth part of an inch is such that they require, to produce a given intensity, at least a hundred times the quantity of electricity that would have produced it in either singly and apart. The redundant electricities in the masses under consideration will therefore be unequally distributed; the plate A will have about ninety-nine parts, and the plate C one; and for the same reason the revolving plate B will have ninety-nine parts of the opposite electricity, and the ball D one. The rotation, by destroying the contacts, preserves this unequal distribution, and carries B from A to C, at the same time that the tail K connects the ball with the plate C. In this situation the electricity in B acts upon that in C, and produces the contrary state by virtue of the communication between C and the ball; which last must therefore acquire an electricity of the same kind with that of the revolving plate. But the rotation again destroys the contact, and restores B to its first situation opposite A. Here, if we attend to the effect of the whole revolution, we shall find that the electric states of the respective masses have been greatly increased; for the ninety-nine parts in A and in B remain, and the one part of electricity in C has been increased so as nearly to compensate ninety-nine parts of the opposite electricity in the revolving plate B, while the communication produced an equal mutation in the electricity of the ball. A second rotation will of course produce a proportional augmentation of these increased quantities, and a continuance of turning will soon bring the intensities to their maximum, which is limited by an explosion between the plates."

Ronalds pendulum doubler. Plate CCXXVIII. fig. 18.

An ingenious instrument, called a *pendulum doubler*, has been recently constructed and described by Mr Ronalds. Having found it necessary to keep a telegraphic wire constantly electrified with a very small source of electricity, he converted the bob of a pendulum into the centre plate of a doubler, and he found the instrument thus modified not only useful for that purpose, but also for that class of experiments, such as those on vegetation and animal life, which require a constant supply of small quantities of electricity to repair the loss occasioned by unavoidable defective insulation, either in the glass which is used, or in the surrounding atmosphere. This improvement on the doubler is shown in fig. 18, where A and B are the two fixed plates, about 4 inches in diameter, supported by glass pillars; C is the bob carried by the pendulum rod D, and insulated by the piece of glass *e*. The form of the bob C is that of a plano-convex lens, with its interior filled with lead; *f* is a small cylinder connected to C with screws, which also adjust the plane of C parallel to the plane of vibration; *g* is another insulating glass rod, carrying the bent wire *h*, the left end of which lies nearly in the same vertical plane as the end of the wire *m*, the right end being nearly in the same plane as the end of the wire *n*. A wire, *i*, rises perpendicularly from C; and another, *k*, perpendicular to the plane of vibration, is fixed into the brass cup at the end of the pendulum rod. A wire,

Electrical Apparatus.

l, is screwed into the edge of the plate B, and the long wire *m* is fixed on the lower edge of B, so as to approach within a small distance of A, where it is bent at right angles, and then projects in a plane perpendicular to that of vibration. Another wire, *n*, is fixed into the edge of A, so as to bend and project similarly; but *n* projects farther than *m*, that the right side of the bow *h* may pass the end of *m* without touching it. A wire, *o*, is fixed at right angles into the base of the instrument.

When the bob C is exactly opposite A, the insulated wire *h* touches simultaneously the ends of the wires *m* and *n*, and establishes a communication between A and B, while at the same time the wire *i*, by touching *o*, forms a communication between C and the ground. Now, if a quantity of *positive* electricity, for example = 1, is given to A or B when the centres of A and C are opposite to each other, that quantity will be nearly all condensed on A, and C will acquire *negative* electricity nearly = 1.

"If C," says Mr Ronalds, "be now allowed to begin its vibrations, the connection of A and B with each other will be instantly broken, as also that of C with the earth, and they will be all insulated, and all retaining the electric states which they possessed before the connections were broken (*i.e.*, A will be positive nearly = 1, B negative nearly = 1, and C positive almost 0).

"When C has arrived opposite B, the *uninsulated* wire *k* will touch the wire L, and thus place B in connection with the earth; therefore C, by virtue of its negative charge, will induce a positive charge in it nearly = 1.

"When C arrives a second time opposite to A, all the former connections will be re-established, and the charge of B will (by means of the wire *m*) be nearly all condensed on and added to the original charge of A, making a tension nearly = 2 of positive electricity, which tension will induce a tension of nearly = 2 of negative electricity on C.

"And so the charges in A and C would go on, nearly *doubling* at each vibration of the pendulum, until their tensions would arrive at such a point as to cause a spark to pass between them.

"But P is a Leyden jar furnished with a Lane's discharging electrometer *q;* a connection is established by means of a small chain between it and A; and the distance between the two balls *r* and *s* is considerably less than that between A and C; therefore the spark will be given to the jar, and a spark will be continued to be given at the completion of almost every second vibration, until it is charged almost as highly as A is capable of being charged, or the sparks will continually supply the loss of electricity by any defect of insulation, either of the jar, or of any conducting body in connection with its interior coating within certain limits.

"The contacts of the wires do not impede the velocity of the vibrations, because they are made small enough to act as springs of a required force; but the electric attractions of the plates and bob *do* tend to do so. The pendulum is suspended by two springs, placed one at each extremity of a cross piece, to which the rod is attached, for the purpose of preventing the bob from being drawn, by their attractions, out of its assigned plane of vibration, as much as possible."

SECT. III.—*Description of Instruments for Multiplying Electricity.*

Multipliers of electricity.

The electrical multiplier invented by M. Cavallo is shown in fig. 19, on a scale about one-third of its real size, and is chiefly useful in ascertaining the presence of a considerable quantity of electricity occupying an extended space. Its principal parts are four plates of brass A, B, C, D. The plates A, C are supported by two glass rods G, H, fixed in the wooden base RSQ. A similar plate B is supported by another glass rod I, cemented into the wooden lever LK, moving round a pivot K. The fourth plate D is supported by a metallic rod. By the lever KL the plate B can be moved from its position on the figure into the dotted position KX. The plate D is screwed at P into a piece of brass FP, which slides in a groove, so that D can be pulled out to any distance from C. At the corner Q is fixed a brass rod N, and O*m* is a small bent wire fixed to the brass socket O on the back of B. When B is as near as possible to A, their distance being one-twentieth of an inch, this wire *m* touches the rod N, and forms a communication with the earth; when FP is pushed in as far as possible, the surfaces of C and D are one-twentieth of an inch distant. As the lever KL moves towards X, the end *m* of the wire *m*O quits N and insulates the plate B; and when the lever has the position KX, the wire *m* will touch the plate C, so as to put the insulated plates B into communication with each other.

Cavallo's multiplier. Plate CCXXVIII. fig. 19.

If a body weakly electrified positively is now made to touch A, when A and B are placed together as in the figure, A will acquire a greater quantity of positive electricity from the presence of the uninsulated plate B, which will be negatively electrified. When KL comes into the position KX, so that B touches C by the wire *m*O, its negative electricity will pass almost wholly to C, owing to its proximity to D, which communicates with the ground. By a number of successive oscillations of the lever between the two positions KL and KX, this operation may be repeated till an accumulated charge of negative electricity has been fixed upon C. The plate D must now be drawn away from C by means of the slider FP, and if pith balls are presented to C they will diverge with negative electricity.

Schweigger's multiplier.

In our chapter on the chemical agencies of electricity, we have already described Schweigger's multiplier or galvanometer, which was used by M. Colladon in his experiments on the chemical action of ordinary electricity; and also the multiplier of Dr Faraday with a double helix, which he employed in his researches on the identity of the electricity of the machine with that of the pile. Various improvements have been made on the multiplier by M. Nobili, Professor Oersted, and others; but we must reserve our account of them for the articles GALVANISM and MAGNETO-ELECTRICITY.

CHAP. III.—DESCRIPTION OF INSTRUMENTS FOR INDICATING THE PRESENCE OF ELECTRICITY, AND MEASURING ITS QUANTITY.

Indicators and measurers of electricity.

Instruments which are intended merely to indicate the presence of electricity are called *electroscopes*, while those which are intended for measuring the quantity of electricity are called *electrometers*. The earliest electrometer which seems to have been employed was a pair of silk threads, which indicated the presence of small quantities of electricity by their divergence; and the Abbé Nollet even attempted to measure the quantity communicated to them, by determining the inclination of the two threads, from their shadow on a board. Mr Waitz improved the instrument by suspending small weights to the threads, and Mr Canton perfected it by substituting the finest linen threads for the silk ones, and by suspending from them a pair of small balls turned out of the dry pith of the elder.

Description of Cavallo's Electroscope.

Cavallo's electroscope.

M. Cavallo made this little instrument portable by fitting it up as in fig. 1, where it is shown in a state of action at

Electrical Apparatus.

B. When it is unloosed, the end B carrying the pith balls is screwed off. and the balls are put into the glass tube at A, which serves for a handle. This glass case is three inches long and three tenths of an inch wide, and half of it is coated with sealing-wax. A cork tapering at both ends is made to fit the mouth of the tube, and to one end of the cork are fixed two linen threads carrying two small cones of elder pith. The case of the electrometer at C incloses at one end a piece of amber for giving negative electricity, and at the other end a piece of ivory insulated upon a bit of amber for giving positive electricity, to the balls, when rubbed with a piece of woollen. All these instruments may be greatly improved by substituting for the pith of elder the pith of the sola, a tree which grows in the East Indies.

Cavallo's electroscope. Plate CCXXIX., fig. 1.

Description of Bennet's Gold-Leaf Electrometer.

Bennet's gold-leaf electrometer, figs. 2, 3.

One of the most useful electrometers is that which was invented by Mr Bennet, and called the gold-leaf electrometer. This instrument, which is shown in fig. 2, and a section of it in fig. 3, consists of a cylinder, ABED, with a broad brass cap, AB. In a hole, *a*, in the centre of the cap, is fixed a wedge of wood, on each side of which is fastened by a little varnish a smooth-edged strip of gold leaf, shown at *m* and *n*, about two inches long and a quarter of an inch broad. Two pieces of tinfoil, *b*, *c*, are pasted opposite each other, and within the cylinder, so as to rise a little higher than the ends of the gold leaves, and the lower ends of these pieces of foil are in contact with the brass stand DEF which sustains the instrument. The inside of the cap AB, and the upper part of the glass cylinder, are sometimes coated with wax. A pointed wire, C, is used to collect the electricity af the atmosphere. In using this instrument, the cap AB is turned round till the surfaces of the gold leaves are parallel to those of the pieces of tinfoil. When no electricity is present the two gold leaves hang in contact in the axis of the cylinder; but if a fully electrified body is made to touch the cap AB, the gold leaves *m*, *n* will diverge as in the figure, and their lower ends will strike the pieces of tinfoil *b*, *c*, which will convey the electricity to the ground.

Mr Nicholson has proposed to substitute two flat radii of brass in place of the tinfoil, and by moving them to and from the gold leaves with a micrometer screw, to make the instrument more sensible, and at the same time obtain a kind of measure of its quantity.

Singer's Improved Electrometer.

Singer's improved electrometer. Plate CCXXIX., figs. 4, 5.

Although insulation may be procured by coating glass insulators with wax, yet, as Mr Singer observes, this affords only a temporary defence, as moisture is eventually precipitated upon them; and in removing this it is almost impossible to avoid exciting the surface of the wax, and disturbing delicate experiments by the electricity which is thus generated. To remove this evil Mr Singer proposes to inclose the insulator in a narrow channel, as the moist air in contact with it would be then limited in quantity, and little disposed to motion. In applying this principle to the improvement of Bennet's electrometer, the insulation is effected by a glass tube four inches long and one-fourth of an inch internal diameter, coated out and in with sealing-wax, and having a brass wire five inches long and one-sixteenth or one-twelfth of an inch thick to pass through its axis, so as to be perfectly free from contact with any part of the tube, in the middle of which it is fixed with a plug of silk, which keeps it concentric with the internal diameter of the tube. This arrangement is shown in figs. 4, 5, where A is a brass cap screwed upon the upper part of the wire

Figs. 4, 5.

w, which prevents the atmosphere from having free contact with the outside of the tube B, and defends at the same time its inside from dust. To the lower end of the wire the gold leaves are fastened, and the glass tube passes through the centre of the usual cap of the electrometer, and is cemented in it near the middle of its length, as may be seen by the dotted lines which represent the cap. "When this construction," says Mr Singer, "is considered, it will be evident that the insulation of the wire, and consequently of the gold leaves, will be preserved until the inside as well as the outside of the glass tube is coated with moisture; but so effectually does the arrangement preclude this, that some of those electrometers that were constructed in 1810, and have never yet (1814) been warmed or wiped, have still apparently the same insulating power as at first." The electrometer constructed upon the preceding principles is shown complete in fig. 4.

Fig. 4.

Dr Faraday's instructions for using electrometers.

Dr Faraday recommends strongly the use of this electrometer; but having found from repeated experience that its indications are not in general well understood by those who have occasion to use it, he has given a very valuable description of the kind of charge which it receives under different circumstances, and the precautions which are necessary in interpreting its indications. As this description would lose its value by any abstract or alteration, we shall make no apology for giving it in his own words, especially as it is applicable to many other analogous instruments.

"If an insulated portion of conducting matter, as a brass ball at the end of a glass handle or silken thread, be electrified, and then placed in *contact* with the cap of the electrometer, the cap and leaves will immediately partake of the electricity of the ball, and the leaves will diverge. If the charge in the ball be of considerable intensity, the leaves will be torn to pieces by their mutual repulsion, and the attraction of the sides of the glass jar; but if the intensity be small, the leaves will diverge moderately, so as not to touch the glass, and the degree of divergence will be in some proportion to the intensity of the charge communicated. The appearances will be the same whether the electricity communicated be positive or negative.

"The circumstances will be different if the body brought in contact with the electrometer is an electrified portion of what is usually called non-conducting matter; if, for instance, it be a stick of sealing-wax rubbed with flannel, instead of a metallic ball. If highly electrified, this will cause the same disturbance and appearance in the leaves during its approach as the ball; if moderately electrified, it will, when in contact with the cap, cause the usual appearance of divergence in the leaves, but upon removing it, the leaves, instead of remaining diverged, will either collapse, or remain very slightly, and frequently uncertainly, electrified. This is a consequence of the non-conducting power of the wax; and the method of transferring electricity to the electrometer in such a case is, to draw the excited parts of the wax over the edge of the cap; small portions will be communicated, and the electrometer will be left electrified similarly to the wax. Such a process is, however, very uncertain; for if the electricity of the wax be weak, the friction of the substance against the electrometer cap will sometimes generate an electricity stronger than that previously existing on the surface of the wax, and the electro meter will become charged, not by the previous electricity of the wax, but by that produced during its friction against the cap.

"This difficulty may, however, be avoided in most circumstances, simply by bringing the electrified non-conductor into contact with the cap, and retaining it there during the experiment; for the electricity which in this way is made by *induction* to exist in the leaves, and causes their divergence, is the same as that which would exist over

the whole of the cap and leaves, if the electricity of the wax could be transferred to them.

"Such are the circumstances relating to the charge of the electrometer, by bodies brought into *contact* with it, and communicating to it part of the electricity they previously possessed. As before mentioned, when highly electrified, they cannot be so applied to the instrument without tearing the leaves to pieces; but they may then, when held at a distance, be made to diverge the leaves by *induction*, and even to communicate a charge to the instrument, and thus enable it to exhibit divergencies when the inducing electrified body is removed. The effects thus produced by induction are the same in kind, and nearly in extent, whether the electrified body be a mass of conducting or non-conducting matter, so that in this respect the metallic ball and the stick of wax are equal; the only difference being in the kind of electricity produced, which, with bodies charged positively, is the reverse of that occasioned by such as are charged negatively.

"When an electrified substance is placed at such a distance from the cap of the electrometer as to occasion considerable divergence, and is retained there for a few minutes, the divergence of the leaves will generally diminish, and the more rapidly as the instrument becomes cold or the glass damp, as the leaves are ragged, or any part of the cap angular and pointed.

"On removing gradually the electrified substance to such a distance that it can no longer affect the instrument, it will be found that the leaves will collapse at first, and afterwards expand again more or less, according as they had lost more or less of their first divergence.

"This ultimate divergence of the leaves will be due to a charge of electricity in the instrument, of the *opposite kind* to that of the inducing or approximated body.

"If no effect of this kind takes place, and there be no diminution of the first divergence, nor any ultimate change, then the insulation and goodness of the electrometer is proved by a powerful test. This being ascertained, then, if whilst the electrified body is in the neighbourhood, and the leaves diverged, the cap be touched by the hand, or any other conducting substance communicating with the earth, the divergence of the leaves will instantly cease. In this state of the instrument, if the communication be broken so as to leave the cap and leaves insulated, they will still remain collapsed; but if the inducing electrified body be now removed from the situation in which it at first caused the divergence, the leaves will immediately diverge, and the electrometer become charged with electricity of the *opposite* kind to that of the inducing body. The degree of charge thus given to the instrument will be in proportion to the degree of divergence induced in the leaves *before* they were made to collapse by the touch of the finger.

"In the case in which a weakly electrified non-conducting substance was directed to be laid on the cap of the electrometer, to occasion a divergence by electricity like its own, it may be observed that, if, during the experiment, the cap be touched by the fingers, and the electrified body afterwards removed, the leaves will first collapse, and then diverge with *opposite* electricity, although at the commencement of the experiment they were diverged with the *same* electricity as that of the body to be examined. If, therefore, the electricity of an excited body is to be examined, the leaves of the electrometer are in the first place to be diverged. This may be done with the *same* electricity, by bringing the body, if *weakly electrified*, into contact with the cap, leaving it there if of non-conducting matter, or removing it after contact if of conducting matter; or, if *strongly electrified*, by approaching it so near as to cause a sufficient divergence of the leaves, and retaining it there until the conclusion of the experiment. On other occasions however with strongly excited bodies, it may be convenient, either because of their size or other circumstances, to communicate a charge of the *opposite* kind, in the manner described; then upon determining what that kind is, in the manner to be immediately described, the electricity of the originally electrified body will of course be known to be opposite to it.

"The tests of the kind of electricity by which the leaves are diverged are of the following nature. A stick of sealing-wax rubbed with warm flannel becomes *negatively* electrified; a tube of warm glass rubbed with a dry silk handkerchief, or, better still, with a piece of silk having a little amalgam upon it, becomes *positively* electrified, both these excitations being so strong as to make the leaves of an uncharged electrometer diverge whilst the wax or glass is at a considerable distance. If one of these excited substances be brought near the cap of an electrometer already diverged, it will either cause the divergence to increase or diminish. The divergence will *increase* if due to electricity of the *same* kind as that of the body approached, but will *diminish* if of the opposite kind; so that the electricity of the body approached being known, that of the electrometer will also be known, and consequently that of the excited body which had originally caused its divergence. The sealing-wax for instance is rendered *negative* by flannel; being approached to a diverged electrometer it may cause the leaves to collapse; the conclusion to be drawn is, that the electrometer leaves were in a *positive* state: being approached to another diverged electrometer it may increase the divergence, in which case it will indicate that the leaves of the electrometer were in a *negative* state. An excited rod of glass brought to these electrometers would make the first diverge still more, and would cause the second to collapse, in both cases indicating the same states as the wax.

"Some precaution is required with respect to the manner in which these excited rods are to be applied. The electrometer being diverged, the wax or glass is to be excited at such a distance as to have no influence over the instrument; the most strongly excited part of the wax or glass is then to be gradually approached to the cap, the hand and all other unnecessary conducting bodies being kept out of the way as much as possible, or at least not moved in the neighbourhood of the electrometer during the experiment. As soon as the rod begins to affect the leaves (even though the distance be two or three feet), the effect must be watched, and then their collapse or further divergence will become evident immediately on moving the rod a little way to or from the instrument.

"It is this first effect that indicates the kind of electricity in the electrometer, and not any stronger one; for although, if the repulsion be increased from the first, no approach will cause a collapse to take place except the actual discharge of the leaves against the sides of the glass, yet when collapse is the first effect, it may soon be completed, and repulsion afterwards occasioned from a too near approach of the strongly excited test-tube. It is, therefore, the first visible effect that occurs, as the test-rod is made to approach from a distance that indicates the nature of the electricity; and when this effect is observed, the rod should not be brought nearer, so as permanently to disturb the state of the electrometer, but should be removed to a distance, and again approached, for the purpose of repeating and verifying the preceding observation.

"It is to be understood, that the approach of the test-rod, though it affects the divergence, causes no permanent change of the electricity in the instrument, unless it be brought much too near, and cause considerable disturbance of the leaves. The electrometer will remain, after a good experiment, in the same state as at first.

"When the body to be examined is so strongly electri-

Electrical Apparatus.

fied that it may not be brought near to the electrometer, but has been placed at such a distance as to affect it, and left there to cause a proper divergence, then its place should not be directly over but rather on one side the cap, that the test-tube, when applied, may be brought towards the instrument on the other side; the originally electrified body, and the test-tube, being retained in directions as widely apart as they conveniently can be."

In order to protect his most sensitive gold-leaf electroscopes from the influence of electricity to which they may be exposed, Dr Faraday covers them with nets of linen or cotton with loose meshes, so that when they are placed in the neighbourhood of powerful electrical machines in action, the electricity never reaches them, being wholly taken up by the net which surrounds them.

Saussure's Electrometer.

Saussure's electrometer. Plate CCXXIX., figs. 6, 7.

The electrometer by which Saussure made the observations on the electricity of the atmosphere is shown in figs. 6, 7. It consists of a glass vessel, ACB, of a bell shape, and so wide that the balls *g*, *g*, when at their maximum divergency, cannot reach the strips of tinfoil *h*, *h*, *h*, *h* pasted within the glass. The pith balls, which are spherical, should not be above half a line in diameter, and should be suspended by the finest silver wires, moving freely in nicely-rounded holes. Four pieces of tinfoil are used, each internal piece having a corresponding one on the outside; and the bottom of the instrument is made of metal, and round it there is a graduated scale for measuring the divergency of the balls.

In order to collect much electricity from the atmosphere, the instrument has a pointed wire, one and a half or two feet long, which unscrews in three or four pieces; and in order to preserve its insulation, a small umbrella is screwed on the top of the instrument, see fig. 7. On other occasions he connected with a hook at H a fine metallic wire fifty or sixty feet long, at the end of which was a three or four ounce ball of lead, which he threw to the height of forty or fifty feet, in order to bring down the electricity of the atmosphere.

Fig. 7.

By dividing between two equal and similar bodies the electricity contained in one, and carrying on the subdivision progressively downwards, M. Saussure determined the relation between the divergency of the balls *g*, *g*, and the force of the electricity which acted upon them. The results which he thus obtained are given in the following table.

Distance of Balls in fourths of a line.	Relative Forces of Electricity.	Distance of Balls in fourths of a line.	Relative Forces of Electricity.
1	1	13	23
2	2	14	26
3	3	15	29
4	4	16	32
5	5	17	36
6	6	18	40
7	8	19	44
8	10	20	48
9	12	21	52
10	14	22	56
11	17	23	60
12	20	24	64

Method of using Saussure's electrometer.

In order to use this instrument, place it in open ground, free from trees and houses, and having screwed the conductor on the top of the electrometer, lay hold of it by its base, and place it so that the base and conductor may touch the ground at the same time; then raise it to the height of the eye, and observe on the scale the number of fourths of a line that the balls have diverged; then lower it till the balls almost touch each other, and measure the distance of the top of the conductor from the ground; this distance is the height at which the electricity of the air begins to become sensible. If the balls still diverge, the other parts of the conductor should be unscrewed, and it will then be seen at what height the electricity becomes sensible.

Hare's Single-Leaf Electrometer.

Hare's single-leaf electrometer. Plate CCXXIX., fig. 8.

As the divergency of the gold leaves is increased by the proximity of the strips of tinfoil, Dr Hare, of the university of Pennsylvania, conceives that the leaves are separated by attraction, and not by repulsion; and he was thus led to construct an electrometer with a single leaf, as shown in fig. 8. A brass ball one fourth of an inch in diameter is so situated that it may be made to touch the leaf, or retire from it to the distance of an inch, by means of a screw which supports it. It is obvious that this instrument is not only more simple than the double-leaved electrometer, but less liable to be destroyed by accident; and Dr Hare informs us that it is exceedingly sensible, and that it has enabled him to detect the electricity produced by one contact between a copper and zinc disc, each six inches in diameter.

Henley's Quadrant Electrometer.

Henley's quadrant electrometer. Plate CCXXIX., fig. 9.

This useful instrument is represented in fig. 9. It consists of a semicircle of ivory, C, fixed to the side of a stand, AB, about seven inches high, rounded and smoothed in all its parts. The lower quadrant of the semicircle is divided into 90°, and a thin piece of cane *ab* is suspended at the centre *m* of the semicircle, carrying a pith ball *b*. When the electricity to be measured is communicated to the instrument, the ball is repelled by the stem AB, and the angular elevation of the cane *ab* is a measure of the electrical force. This instrument may be screwed from its base B, and fixed on the end of the prime conductor, or on the summit of a Leyden phial. Mr Achard states from experiment that the quadrant should be divided according to a scale of arcs whose tangents are in arithmetical progression. It is most frequently used as an appendage to the prime conductor, for the purpose of measuring the state of action of the electrical machine.

In employing this instrument to show the progress of the charge of any jar or battery, Dr Faraday justly observes that it should be so placed that the moving index does not approach to any ball, wire, or surface charged similarly to itself, but on the contrary should recede from it. If it is therefore placed on the end of the conductor, the index should move outwards and away from the conductor, and not in a direction over it towards its more central parts; for the latter would interfere with the free indications of the electrometer, and in some cases would make it quite useless.

Brooke's Steelyard Electrometer.

Brooke's steelyard electrometer. Fig. 10.

This electrometer, which is represented in fig. 10, is calculated to measure the number of grains which the repulsive force of the accumulated electricity is capable of raising. Its base AB, about nine inches and a quarter in diameter, adjusted horizontally by screws A, B, sustains an insulating pillar DD, upon which the electrometer rests. To the brass rod H are attached two tubes of copper, G, *g*, which have a motion round the rod, so as to be turned to a proper distance from the body whose electricity is to be measured. The tube G is screwed into a solid piece within the ball F, and moves in a vertical plane about an axis close to F. The balls I K are of copper, and hollow. The arm E, which moves round an axis in a vertical plane behind the dial-plate R, carries a ball C, which touches the ball L fixed on the top of the glass rod DD. If the arm E rises from a vertical to a horizontal position, or through 90°, the index

Electrical Apparatus.

R on the dial is made to move through a whole circle, or 360°. The apparatus NPH forms the communication between the electrometer and the body whose electricity is to be measured.

Let the body be electrified positively, then the electrometer will be similarly electrified. The balls I, K will repel each other, G will rise in a vertical plane, L will repel C, and EC will also rise in a vertical plane.

The apparatus F, G, *g*, I, K, is chiefly used for graduating the inner circle of the dial-plate. For this purpose a weight *m* moves along the rod G, till it forms an exact counterpoise to the weight of F. One end of the weight *m* will consequently be the *zero* of the scale. Let *m* be now shifted to *n*, near to the ball I, and determine by a pair of good scales the weight of the ball I, or rather the weight produced by shifting *m* to *n*. Divide the space *mn* into as many divisions as the grains now found, and subdivide it into halves and quarters. These divisions are now to be transferred to the inner circle of the dial-plate, by observing the position of the upper or shorter half of the index R when *m* stands at any number of grains in the scale *mn*. When the inner scale on the dial-plate is thus graduated, the arms G, *g* and balls I, K may be removed.

Cuthbertson's Balance Electrometer.

Cuthbertson's balance electrometer. Plate CCXXIX., fig. 11.

This electrometer, which is particularly useful for jars and batteries, is shown in fig. 11. It consists of a metallic rod CD, about thirteen inches long, terminated by balls C, D, and balanced on a knife edge, the ball *b* being constructed in such a manner as to permit the rod CD to move in a vertical plane. A bent tube of brass FG, supports a similar ball G; and four inches below D is placed another insulated ball E, which communicates with a wire and chain with the *outside* of the jar or battery. If the rod AB be now connected with the prime conductor, or the *inside* of the jar, and this last be electrified, the ball E will attract D, because they are oppositely electrified, from being connected with opposite surfaces of the jar; and when this attractive force exceeds the weight at *a* with which the opposite arm is loaded, the arm *b*D will descend and give out its electricity to the ball E. In order to obtain a measure of the attractive force between D and E, and consequently of the intensity of the charge, the arm C*b* is divided experimentally into sixty parts or grains, which are indicated by one side of the moveable index *a*. A Henley's quadrant electrometer is placed at A, to indicate the progress of the charge, which is not shown by the balance electrometer.

Sir W. Snow Harris's Electroscope.

Sir W. Snow Harris's electroscope. Fig. 12.

This very ingenious and beautiful instrument, invented and used by Sir W. Snow Harris, is represented in fig. 12. The following description of it we owe to the kindness of the inventor:—

Fig. 12 represents an electroscope, which acts on the principle of electrical divergence. A small elliptical ring of metal, *a*, is attached obliquely to a small brass rod, *ab*, by the intervention of a short tube of brass at *a*; the rod *ab* terminates in a brass ball, *b*, and is insulated through the substance of the wooden ball *m*. Two arms of brass, *r*, *r*, are fixed vertically in opposite directions on the extremities of the long diameter of the ring, and terminate in small balls; and in the direction of the shorter diameter within the ring there is a delicate axis at *a*, set on extremely fine points. This axis carries, by means of short vertical arms, two light reeds of straw, *an*, *an'*, terminating in balls of pith, and constituting a long index, corresponding in length to the fixed arms above mentioned. The index thus circumstanced is susceptible of an extremely minute force. Its tendency to the vertical position is regulated by small sliders of straw, *s*, *s*, moveable with sufficient friction on either side of the axis. To mark the angular position of the index in any given case, there is a narrow graduated ring of card, board, or ivory, *ef*, placed behind it, the divisions being distinctly legible through sights cut in the reeds. This graduated circle is supported on a transverse rod of glass, *cd*, by the intervention of wooden caps, and is sustained by means of the brass ball *a*, in which the glass rod is fixed. The whole is supported on a long insulator of glass, A, by means of wooden caps terminating in spherical ends.

In the above arrangement, as is evident, the index will diverge from the fixed arms whenever an electrical charge is communicated to the ball *b*.

This instrument is occasionally placed out of the vertical position, at any required angle, by means of a joint at *m*; and all the insulating portions are carefully varnished with a solution of shell-lac in alcohol.

Sir W. Snow Harris's Electrometer.

Sir W. Snow Harris's electrometer. Plate CCXXIX., fig. 13.

The object of this electrometer, an account of which has been kindly communicated to us by its inventor, is to measure directly the attractive force of an electrified body, in terms of a known standard of weight, estimated in degrees on a graduated arch, *xy*, fig. 13. An insulated conductor, *f*, is fixed on a varnished rod of glass, *fg*, resting, by the intervention of a wooden ball on the extremity of a micrometer screw, S, by the aid of which the conductor may be raised or depressed through given intervals to within the hundredth of an inch of any required point. A moveable and similar conductor, *m*, made of light wood, hollowed and gilded, is suspended immediately over the former from the periphery of a small brass wheel W, figs. 13 and 14, by means of a fine silver thread attached near its vertical arm, and passing from thence over its grooved circumference, as shown. This conductor, *m*, is counterpoised by a short cylinder of wood, *pn*, figs. 13, 14, suspended in a similar manner from the opposite side of the wheel by means of a silk thread, and resting partly in water contained in the glass vessel N, fig. 13. Figs. 13, 14.

The extremities of the axis of the wheel W, figs. 13, 14, are turned to extremely fine pivots, and rest on two large friction wheels, after the manner represented in the figures,[1] by which great freedom of motion is obtained.

There is a fine index of light straw, W*c*, attached to the extremity of a small steel needle, inserted diametrically through the circumference, which indicates on the graduated arc *xy* the force exerted between the conductors *m*, *f*. The weight of this index is accurately poised by a small globule of brass, *n*, fig. 14, moveable on a screw, cut in the opposite arm of the steel needle carrying the index.

The centre of the wheel W is accurately placed in the centre of the arc *xy*, which, with its radii of support, is made of varnished wood; the graduated scale being of card, board, or ivory. This arc is the sixth part of a circle, divided into 120 equal parts, 60 in the direction *cx*, and 60 in the direction *cy*; the centre *c* being marked zero.

Fig. 14.

Fig. 14 represents the wheel W, with the suspended conductor and counterpoise, the index and its balance-weight, together with the lines of suspension, passing freely over the circumference, and fixed at the point *ii*.

---

[1] Sir W. Snow Harris resorted to this method of employing friction rollers, as being more efficient than that in which the axis is allowed to rest in the angle formed between the peripheries of four smaller wheels. In this case it rolls fairly on a large circumference, and is prevented from passing off it on either side by the check-wheels, either of which, when acted on, opposes little or no resistance to motion.

The various wheels above mentioned, with the graduated arc, are sustained on a projecting metallic rod, passing through a glass column B. The column is secured by means of the rod to a sort of double stand *pp*, fig. 13, supported on three levelling screws. The interval between the plates of this stand contains the glass vessel N and the micrometer screw S. The upper plate has a circular hole, *p*, through which the cylindrical counterpoise passes into the water *n*. The levelling screws serve to regulate the position of the counterpoise through the hole; so that when it hangs in it centrally, the whole is accurately adjusted.

The gravity of the suspended conductor *m* being in the above arrangement opposed by that of the counterpoise, it may be so far considered as existing in free space devoid of weight, and will therefore become very readily moved by any new force applied to it. It may consequently be caused to approach to or recede from the fixed conductor *f*, by the operation of forces acting in either of these directions; the motion, will, however, be speedily arrested by the cylindrical counterpoise *n*, which becoming either further immersed in, or otherwise raised in the water, furnishes, in the greater or less quantity of water displaced, a measure of the force. In this way the force may be estimated either in degrees or grains of actual weight; since the number of grains requisite to add to either side, in order to advance the index in either direction a given number of divisions, may be immediately found by experiment; and which, as the sections of the cylinder are all similar, will be found to increase or decrease with the degrees of the arc. Thus, if one grain advances the index in either direction five degrees, then two grains will advance it ten degrees, and so on.[1]

In the application of this instrument to electrical inquiries, the force to be measured is first communicated to the fixed conductor *f*, a free communication being established between the suspended conductor *m* and the ground, or otherwise with the negative side of the jar or battery, should the attractive force be derived from this species of accumulation; this is readily effected through the brass work of the apparatus, in connection with the rod passing through the interior of the glass column B.

For the repulsive force we connect the conductor *f* as before, and suspend *m* by a silk thread; in which case it will, after being electrified similarly to *f*, recede from it; but this method of experiment is evidently more complicated than the former, and liable to fallacy. The distance between the conductors *m f* corresponding to a given force is easily ascertained by means of the degrees indicated on the arc *x y*. In the instrument above described, each degree corresponds to a variation of distance between the conductors equal to the ·01 of an inch. If, therefore, at the commencement of any given experiment, we first bring the nearest points of the conductors *m*, *f* in contact, the index being in zero, and then depress the inferior conductor *f* a given distance, known by means of the micrometer screw *s*, then all subsequent distances may be readily determined between these points.

It is now only requisite to observe, that the interior of the cylindrical counterpoise is hollow, in order to weigh it accurately, and cause it to hang vertically in the water; and there is a small hemispherical cup, *p*, fixed on its stem for the reception of small adjusting weights, by which the position of the index at 0 of the scale is regulated with great nicety. With respect to the form of the conductors *m*, *f*, they are generally plain circular areas, backed by small cones, and are about two inches in diameter. Conductors of other forms, however, such as spheres and cylinders, may be occasionally used when the object is to experiment more particularly on bodies of peculiar forms.

Experiments with this instrument are remarkably clear, considering the subtile character of the principle we have to investigate. Thus, when the insulations are perfect, and the atmosphere dry, the index immediately exhibits the amount of the attractive force, and remains stationary for a much longer time than is required to note the result.

By varying the superficial dimensions of insulated conductors, and the quantity of electricity accumulated on them, we may, by the help of the above instrument, deduce many curious and important laws of electrical action. It is, however, first requisite to explain a method of charging simple conductors with comparative quantities of electricity; for without an accurate measure of quantity, little can be effected in almost any department of this branch of science.

Plate CCXXIX., fig. 15.

Simple conductors may have comparative quantities of electricity disposed on them, by abstracting small sparks from an insulated charged jar, fig. 15, either immediately on the given substance, or, otherwise, on an insulated transfer plate, *p*, fig. A. An insulated jar, charged with a given accumulation, as estimated by the unit of measure, which will be presently described, is of singular importance in researches with simple conductors; for series of sparks may be obtained from it of such slow convergence, that many successive terms may be considered as equal. Thus, an insulated metallic disc, *d*, being placed in connection with the electrometer, fig. 13, or with the electroscope, fig. 14, was electrified many times in succession to precisely the same amount, by sparks drawn on an insulated plate from the positive coating, the negative side of the jar after each contact being restored to a neutral state. When a portion of the charge was abstracted so as to sensibly decrease the quantity in the jar, then a new point was arrived at, from which another series of sparks can be obtained, differing extremely little in quantity; and this process may be continued to a low point of accumulation on the jar.

Fig. A.

The quantity given off by the positive coating is dependent on the dimensions of the abstracting conductor, and on the free state of the negative side of the jar. If it be free for each experiment, or be otherwise connected with a conductor of sufficiently large dimensions, it may be observed that a conductor of a double capacity receives a double quantity, a conductor of a treble capacity a treble quantity, and so on. The extent to which this process may be carried with a jar exposing about two square feet of coating is somewhat considerable. We only require in these experiments an extremely perfect insulation.

In disposing given quantities of electricity on simple conductors in this way, and investigating the attractive force by means of the electrometer, Sir W. Snow Harris arrived at the laws formerly explained. (See page 550.)

Lane's Discharging Electrometer.

Lane's discharging electrometer.

This admirable instrument is shown in fig. 16. To the stem AB of a Leyden jar MN, is fixed a bent piece of glass BC, for the purpose of supporting and insulating the brass rod DE, which has two equal brass balls at its extremities. This rod moves through a spring tube at C, so that the brass ball D can be placed at different distances from the equal ball A, by which the jar is charged. The insulated ball D is connected through the metallic wire DE with the outside coating of the jar, by a wire EF. If we bring the ball D near to A, a small electrical charge conveyed to the jar MN will discharge itself from A to D, and

[1] The counterpoise should be free from grease or varnish of every sort, and should, previously to being used, be kept immersed in water; the insulation of the conductor *f* also should be made extremely dry, and occasionally warmed by a stick of burning charcoal.

Electrical Apparatus.

pass off to the ground by the wire EF. If the distance AD is increased, the jar must be more highly charged before it discharges itself; so that the distance AD of the balls is a measure of the intensity of the charge at the time of its discharge. As long, therefore, as the jar has not discharged itself, we are sure that its charge is less than that which corresponds to the distance AD. The chief defect of this instrument arises from the occasional interposition of particles of dust or other light conducting materials between the balls, which occasions the charge to take place sooner than it otherwise would do. The arm of glass is sometimes fixed on the top of the charging rod, where a ball of wood is placed, and is bent downwards, so as to carry the balls D, E. In this case the jar is charged by another ball projecting from the charging rod towards D. This electrometer is sometimes fixed to the prime conductor, with and without a jar accompanying it.

Sir W. Snow Harris's Measuring Electrometer.

Sir W. Snow Harris's measuring electrometer.

This elegant instrument, which we have had the advantage of seeing in operation, is an invaluable addition to our electrical apparatus. According to the law of electrical accumulation on coated jars, 'the quantity added to one side is always proportional to the quantity given off by the other, and reciprocally. Hence the amount of the accumulation may be always estimated by insulating the jar to be charged, and observing, by means of a discharging electrometer, the explosions of a small jar connected with the negative coating. This process is, however, complicated in its general application; but Sir W. Snow Harris has modified it in the following manner:—Let a small jar, N, be furnished with a discharging electrometer, *n*, and inverted as in fig. 17, being supported by a brass rod, *pq*, inserted into the ball D of the prime conductor ABC. Then, as the electricity passes up the rod and accumulates on the inner coating, a similar quantity is given off from the outer coating, which may be made to pass from a ball at *p*. Now, when the small jar N has been charged to a given degree, an explosion or discharge takes place from *m* to *n*, and restores the equilibrium; and hence *one measure* of electricity is marked by the first explosion. When this has taken place, the jar is in the same state as at first; and hence by a repetition of the process we obtain the exact number of measures (or explosions) which pass from the unit jar N, and are finally accumulated on the jar J, or battery, into which the electricity passes from the ball *p*. This process of charging a battery from the outer coating of an exploding jar, instead of from the prime conductor, supersedes all electrometers, and is the best way of measuring quantity.

Plate CCXXIX., fig. 17.

Volta's Flame Electrometer.

Volta's flame electrometer.

It was observed by Mr Bennet, that a lighted candle placed above the cap of his electrometer, and communicating with it, greatly increased the sensibility of the instrument; and it appears, from various experiments, that flame possesses the property of carrying off from bodies the electricity with which they are charged. M. Volta ingeniously availed himself of this principle in order to bring down to his electrometer the electricity of the atmosphere, the nature and intensity of which he was desirous of examining. This effect is produced by elevating above the atmospherical conductor a lighted match or torch.

Matteucci's Phosphorus Electrometer.

Matteucci's phosphorus electrometer.

As the preceding instrument cannot be employed when there is the least wind or rain, and still less during a storm of hail or wind, M. Matteucci conceived the idea of constructing an electrometer depending on the strong conducting power of the vapour of phosphorus. He prepared rods of this substance between the twenty-fifth and the fiftieth of an inch in diameter, by melting the phosphorus under water, and by blowing it while in a state of fusion through a tube of the requisite diameter. He afterwards made the rod of phosphorus project from the fiftieth to the seventy-fifth of an inch beyond the end of the tube. He then fixed the glass tube on a wooden pole, and he insulated the pole by fixing to its extremity a glass handle. The phosphorus communicated by its base with a metallic wire which descended along the pole, and which could be kept at a distance from the pole by some tubes of glass placed at regular distances. M. Matteucci kept the rod of phosphorus perfectly insulated in the time of rain, by means of a glass hood varnished on both its surfaces, and having its convexity turned upwards. The pole was composed of three or four rods, which were adjusted into one another; and the instrument thus constructed was found extremely useful in examining the electricity of the atmosphere.

Mr Ronalds' Improvements on Electrometers.

Ronalds' improvements on electrometers.

As threads, pith or cork balls, and even straws when very dry, lose some of their conducting power, Mr Ronalds prefers fine silver wire, and hard charcoal balls from boxwood, for electrometric purposes. The following is the method which he employs in making electrometers of this kind. The instrument which he uses is represented in fig. 18, where ABCD is a bow of steel wire with a hook at each end. When the charcoal ball has been threaded on the silver wire, and rings formed at each end, it is *very* gently stretched in this bow, by passing the hooks through the rings, and shoving it forward with the thumb placed against the end of the tongue near the handle, which tongue is thus made to open wider by pressing the screw E on each side. The screw E is then turned a little farther into the piece F, in order to fix it firmly. The fine wire is now placed cautiously upon a piece of iron, a little below a red heat, which will make it perfectly straight, when it may be taken from the bow, and suspended on one of the rings of the piece of brass, fig. 19. In fig. 20 is shown Mr Ronalds' method of making gold-leaf electrometers.

Plate CCXXIX., fig. 18.

Figs. 19, 20

Melloni's Electroscope.

Melloni's electroscope.

When a conductor in a neutral state approaches an electrified conductor, it disguises[1] or dissimulates a portion of this electric state, and in restoring to the disguised fluid its positive tension in proportion as the sensible fluid passes from it by dispersion, it prolongs the duration of the electric charge. We know also that this effect takes away from the contrary electricity developed by induction in the part nearest to the body introduced, and that the electricity homologous to that of the inducting body appears on the more distant portions, where it diffuses itself in proportions inversely as the radii of curvature.

A fortunate combination of these three data led M. Melloni to conceive it possible to construct an electroscope singularly sensible, and capable of preserving its electricity a much longer time than any instrument of the same kind. The effect of the instrument is such as he expected, and he regards it as one which will become very useful in all kinds of electrical researches.

Let A (fig. 13) be a metallic cup furnished with two filiform appendages D, D soldered to the opposite points of

[1] See page 613, col. 1.

the upper margin of the cup, and communicating by a conductor which passes into the axis of a tube of glass

Fig. 14.

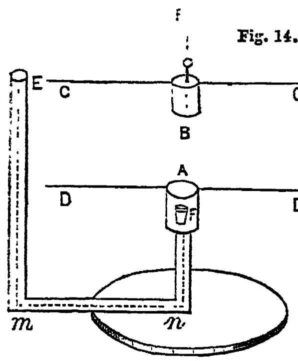

Fig. 13.

having a ball or a metallic disc at E. A second metallic cup B (fig. 14), inverted, and a little smaller and much lighter than A, is fixed below a wire or very thin lever of metal CC, suspended by a silk fibre F. The cup B is then suspended in the manner shown in fig. 15, so as to

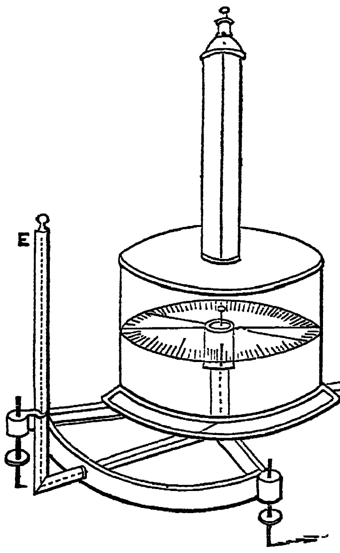

Fig. 15.

be inclosed in A without touching it. A small metallic cylinder *f* is placed in the middle of the cup A, so as not to touch the inside of the cup B.

If we now electrify positively the ball or conductor E, the electricity will pass to the cup A, will act by induction on the cup B, will repel the positive and attract the negative electricity of the natural fluid in B, which will react upon the free fluid in A, disguising a certain quantity and abandoning the rest according to the laws which regulate the distribution of electricity in insulated conductors, so that the intensity of the action will depend on the curvature of the surfaces, and will be less strong on the sides of the cup than upon its appendages. The cup A will therefore contain a certain proportion of positive electricity disguised, that is accumulated without tension and without mobility, and its appendages D, D will possess a free electricity of the same kind increasing towards their extremities. The cup B and its lever CC will possess negative electricity disguised at the central part in respect to the cup A, of free positive electricity in the rest of the moveable system, that is upon the top plate of the inverted cup B, and on the lever above it. But this last species of electricity will be more powerful at the extremities of the lever, than in the middle part or on the top of the cup; 1. Because these extremities are the most distant points of the inductive action; and, 2. Because their radius of curvature is smaller than that of any other part.

As the lever CC thus possesses the same kind of electricity as the appendages DD, it will be energetically repelled if it is not precisely in the same azimuth with them, and after a few oscillations it will rest at a certain angle of deviation. The electric charge communicated to the fixed system will then begin to diminish. This diminution will be much slower than in ordinary electrometers.

In this electrometer the moveable part is always electrified by induction, and never by communication; the difference of form between the centre and the extremities of the fixed and moveable pieces makes the distribution of the moving forces the most favourable for the rotation of the index, and the inductive action of the central surfaces, disguising a portion of the electricity to give it by degrees the free state in proportion to the losses sustained, prolongs the duration of the charge received. The following are the dimensions of the instrument:—

	Millim.
Diameter of glass cage	115
Height of do	11
Length of fibre of silk	25
Distance between dial and glass plate	3
Inner diameter of A	21
Do. do. of B	16

Sir W. Snow Harris's Bifilar Balance.

Sir W. Snow Harris's bifilar balance.

About the year 1831, Sir W. Snow Harris proposed a new method of obtaining a delicate reactive power applicable to the measurement of electrical and magnetic forces, and the movements of oscillating bars and other suspended masses.

If a magnetic or electrical needle, as $p\,n$, No. 1, fig. 16, or other body, G, No. 2, be suspended horizontally by two

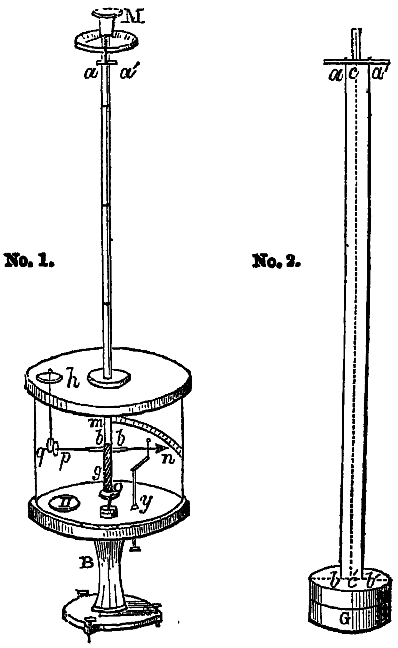

Fig. 16.

equal filaments of unspun silk $a\,b$, $a'\,b'$, fixed parallel to each other, it is evident that its position of rest will be in the vertical plane passing through the two threads. Whenever, therefore, we turn the needle from this position about the imaginary axis $c\,c'$ fig. 2, the filaments of suspension will be deflected from the vertical, so that the distance $c\,c'$ will be somewhat less than before: hence arises a reactive force derived from the weight of the suspended needle or other body, the centre of gravity of which having been raised,

Electrical Apparatus.

Harris's bifilar balance.

will endeavour to descend and rest in its previous position—it will be in a similar condition to that of a body falling down a very small arc. If therefore the needle be freely abandoned to this reactive force, a vibratory motion will arise,[1] by observing which, we may determine the laws of the reactive force imparted to the threads.

By carefully noting the rate of oscillation of a suspended cylinder of wood G, No. 2, about 2 inches high and 2 inches diameter, the following results were arrived at:—1. The time of an oscillation is as the square root of the length of the threads of suspension divided by their distance apart, without reference to the weight of the suspended mass. 2. The oscillations are isochronous at all angles. Applying the general formula $n = \frac{P\pi^2 a^2}{2gT^2}$, employed by Coulomb in his experiments on torsion; it is found that the force imparted to the threads $= n$, will vary with the squares of the distances between them divided by their lengths, and will be also as the weight of the suspended mass $=$ P, hence we have $n \propto \frac{Pd^2}{l}$; and since the oscillations are isochronous, we may conclude that n is proportional to the angle, or perhaps more nearly the sine of the angle, of deflection of the threads, results which the inventor fully verified by experiment.[2]

Upon these data the electrometer, termed by the inventor a bifilar balance, was designed. The instrument, as at first constructed, is somewhat elaborate in its form and contrivances for estimating and observing rapidly electrical forces, to which end it is remarkably available. It will be found very fully described in the *Philosophical Transactions* for 1836. A more simple form of it, however, is that similar to the torsion balance already described, fig. 1, Plate CCXXIV., substituting the bifilar suspension for the wire of Coulomb.

The two threads $a\,b$, $a'\,b'$, No. 1, fig. 16, are secured above to a small cross wire $a\,a'$, at the extremity of a vertical rod terminating in a micrometer and index M; they are about 20 inches long, and are set at a quarter of an inch apart; the electrical needle $p\,n$ is attached to the lower extremities of the threads, in a similar way, and is constructed much in the same way as the needle of Coulomb's balance of torsion, except that the repelling bodies p, q are thin discs of gilded cork of about ·5 of an inch diameter, and the extremity n of the needle balancing the insulated disc p, is formed into an index, and moves over a graduated quadrant $m\,n$ within the glass cage, thereby indicating more accurately the degrees of repulsion of the electrified bodies $p\,q$. The suspension threads are further stretched by a vertical cylinder of brass g, carrying a small stage o for receiving such small circular weights as may suit the purpose of the experimentalist. The lower portion of the cylinder g terminates in a fine needle, which plays freely in a hole drilled in a small elevated plate of brass beneath, as seen in the figure; and by which the whole is prevented from swinging out of a vertical position. The whole is mounted on a raised base of varnished wood B, supported by three levelling screws, and there is a pretty large opening in the floor at H, for the purpose of introducing any small electrified body, and communicating a repulsive force to the discs p, q. To avoid a collapse of the threads when the angle of deflection is considerable, the threads pass through one or two stays of light cork: with this precaution, the force is strictly proportional to the sine of the angle of deflection up to 360°. The angle, however, for all practical purposes need not exceed 60°. There is a small angular lever y moveable with friction through the floor of the glass cage, by which the needle is prevented from taking a violent swing when the repulsion commences, and by which it may be eased off gradually. In the instrument thus constructed, a force so small as the $\frac{1}{1000}$th part of a grain for each degree may be measured: by increasing the length of the threads, diminishing their distance apart, or changing the weights on the stage o, almost any very small fraction of a grain may be obtained and valued. This instrument may be used pretty much in the same way as Coulomb's balance of torsion before described, fig. 1, Plate CCXXIV. The inventor is of opinion, that in experiments with this, and all similar instruments, the electricity should be equal on each of the repelling bodies p, q; the force will be then, at a constant distance, always as the square of the quantity of electricity, as clearly proved by Cavendish in his manuscript papers, and as he himself has fully shown for attractive forces. If one of the repelling bodies p be in a higher state of electrical charge than the other q, then the result is very uncertain—the indications may, in some instances, be nearly as the quantity on one of the discs; but this is not always the case. It is clear, that by continually diminishing the quantity on one of the discs, we shall at length arrive at an attractive force; and to this, under every circumstance, the action of the discs on each other virtually tends, as he thinks he has fully shown.

When it is found desirable to examine the repulsive force in connection with electrified bodies placed externally to the glass cage, then the disc q is attached to a light conducting-wire, terminating above in a contact ball, and insulated through a varnished tube of glass in the hole h, after the manner of the gold-leaf electrometer.

The electroscopes of the Abbé Haüy, and the torsion electrometer of Coulomb, have been described in a preceding part of this treatise.

CHAP. IV.—ON MISCELLANEOUS ELECTRICAL INSTRUMENTS.

1. *Sir W. Snow Harris's Electrical Balance or Scale Beam Electrometer.*

Sir W. Snow Harris's electrical balance. Plate CCXXX., fig. 1.

In investigating the law of the attractive forces of electricity accumulated in jars and batteries, Sir W. Snow Harris made use of the electrical balance shown in fig. 1. The beam mn of the balance, constructed in the usual manner, is suspended from a projecting arm of brass, ea, supported by a vertical stand, abc, consisting of a brass slider and socket, ab, by which the balance can be moved up or down, and of a glass tube, bc, with a ball of varnished wood, b. A wire, pointed out by the line ef', passes through the tube abc, and connects the beam with the *negative* coating of the jar. A hollow gilt conductor of wood, f, is suspended by a metallic thread from one of the arms m, and from the opposite arm n is hung by silk lines a light brass scale, d. In this scale there is placed as much additional weight as will balance the conductor f, and put the whole in a state of equilibrium. By means of an insulated conductor f', of the same dimensions as f, and fixed directly under it, the attractive force of the electricity in the jar is made to act directly on the suspended conductor f. The conductor f', which is connected with the positive coating, is so placed that it can be depressed from contact with the conductor f, through given distances, by means of a cylindrical slide, r, attached to it, which moves in the socket s, and indicates its depression on an engraven scale, divided into twentieths of an inch. The socket s is supported on a glass pillar by means of a var-

[1] *Edin. Trans. for* 1834, Oscillations of the Horizontal Needle, sec. 29.

[2] *Phil. Trans. for* 1836, p. 419.

Electrical Apparatus.

nished ball of baked wood, on which the socket is fixed, and through which the conductor *f'* is connected with the positive coating. The whole balance can be raised or depressed through a small distance by the micrometer screw at *e*.

From this description it is obvious that the attractive force acts directly between the conductors *f* and *f'*, and can therefore be measured by weights placed in the scale *d*. The scale rests on a small circular stand *q*, which can be raised or depressed by the sliding brass rod and tube *vt*, to accommodate itself to the horizontal position of the beam, and to check any oscillation. The balance is fixed on an elliptical base, having three levelling screws.

The following experiment, made by Sir W. Snow Harris, will best explain the use and value of this balance.

Having connected the inside coating of a single jar containing five square feet with the conductor *f*, and the outside coating with the wire *ac*, the conductor *f* was depressed through half an inch, and a weight of sixteen grains was placed in the scale; then, when five turns of the plate were completed (or, if the measuring electrometer is used, when *n* explosions were conveyed to the jar), the attractive force between *f* and *f'* was sufficient to tip the beam. The accumulated electricity being discharged, the conductor *f'* was depressed through a *second interval of half an inch*, making the whole distance *one inch;* and *four grains* or one-fourth of the former weight being placed in the balance, the beam was again depressed with *five* turns of the plate, or *n* explosions of the measuring electrometer. The accumulation being again discharged, and the conductor *f* depressed through a third interval of half an inch, and one-ninth part of the first weight placed in the scale, the beam was again depressed with five turns of the plate, or *n* explosions. Hence, as the distances in the first experiment were as two to one, and the weights four to one, and as in the second experiment the distances were three to one and the weights nine to one, we may infer *that the attractive force between the conductors varied in the inverse ratio of the square of their distance.*

2. *Dr Ure's Detonating Eudiometer.*

Dr Ure's detonating eudiometer. CCXXX., fig. 2.

The electrical eudiometer is a simple instrument, for detonating or exploding gases by means of an electrical spark or shock. The common eudiometer is merely a short tube of glass closed at the upper end, and having two pieces of platina wire passing through the glass near its upper end, so as nearly to meet at the axis of the tube. These wires communicate, the one with the inner and the other with the outer coating of a charged jar, so that when the discharge passes between the platina points, it inflames the gas in the tube. As the gas subjected to the action of the spark is transferred to the tube over water or mercury, the lower or open extremity of the eudiometer must be kept in the water or mercury, in order to confine the gas. With the common eudiometer two persons are required, the one to manage the instrument and the other to manage the electrical machine; but Dr Ure has given it such a form that a single individual can perform all the operations with the greatest facility.

CCXXX., fig. 2.

Dr Ure's instrument, shown in fig. 2, consists of a glass syphon, ABC, with a bore of from two-tenths to four-tenths of an inch. Its legs AB, CB are from six to nine inches long, and from one-fourth to half an inch apart. The open end A is slightly funnel-shaped, and the other, C, which is hermetically sealed, has two platina wires, *a*, *b*, inserted near it by the blowpipe. The outer end of the one wire is bent vertically upwards, and then horizontally so as nearly to touch the edge of the aperture A. The end of the other wire is formed into a little hook, to allow a small spherical button, *d*, to be attached to it when the electrical spark is to be transmitted. The sealed leg CB is graduated by introducing in succession equal weights of mercury from a measure glass tube. Seven ounces troy and sixty-six grains occupy the space of a cubic inch, and thirty-four and a half grains represent a hundredth part of that volume.

The method of using this apparatus is shown in fig 3. Fig. 3.
The whole syphon being filled with mercury or water, a convenient quantity of the gas to be examined, not exceeding one-sixth of the capacity of the tube, must then be introduced in the ordinary manner. The tube is then held upright by the hand, and the gas being transferred into the sealed leg CB, the mercury is brought to a level in both legs, either by the addition of a few drops, or by displacing a portion by pushing down a glass or wooden rod. The tube being grasped as in the figure, the thumb must be placed tightly over the aperture, so as to close it, and at the same time touch the wire next it. A spark from the conductor of the electrical machine is then made to enter the button *d*, and after inflaming the gas, is conducted away by the thumb and hand of the operator, the tip of the finger feeling only a slight push or pressure. When two or more inches of air are left beneath the thumb, it acts as a recoil spring to restrain the violence of the explosion. When condensation of volume takes place, the finger feels pressed down to the orifice. On sliding it gradually to one side and admitting the air, the mercurial column in CB will rise above that in AB. More mercury must then be poured in till the equilibrium is restored, when without any reduction we may read off the resulting volume of gas. If the charge of a jar is to be transmitted through the wires, the thumb must not touch the wire when it closes the aperture. In this case the wire from the outside coating must be hooked on the eudiometer wire nearest the thumb, and then the knob or ball on the charging rod of the jar must be brought in contact with the button on the other wire, when the gas will be exploded.

3. *Volta's Electrical Lamp.*

Volta's electrical lamp.

As hydrogen gas is readily inflamed by a very small electrical spark, Volta conceived the idea of constructing a lamp for temporary purposes, such as that of obtaining a light at night, or in summer for the purpose of sealing letters, by employing the electrophorus to light the hydrogen. With this view a quantity of gas is put into a reservoir, and when subjected to the pressure of a column of water, it escapes from a small aperture by turning a stop-cock. Beneath this reservoir is placed an electrophorus in a box, and from the upper part of the box a wire passes through a glass tube to the small aperture. When the handle of the stop-cock is opened to let out the gas, the cover of the electrophorus is raised by means of a silk cord connected with the handle of the stop-cock, and the spark from this cover is conveyed by this insulated wire to the stream of gas, which is instantly kindled, so as to allow a candle to be immediately lighted. From the smallness of the quantity of gas consumed, a light may be procured an hundred times from the same reservoir of gas. When the hydrogen gas is expended, it is troublesome to persons unaccustomed to chemical manipulations to replenish the reservoir with fresh gas. M. Gay Lussac removed this defect by suspending a bar of zinc on the apparatus, so as to reproduce, by the action of diluted sulphuric acid[1] upon it, as much gas as was exhausted.

Mr Cutbush's improvement upon it.

Although a good electrophorus, when well excited, will retain its charge for many months, yet in general its opera-

[1] The acid should be diluted in the proportion of one part of acid to seven of water.

Electrical Apparatus.

tion has been so uncertain, especially in damp weather, that many persons have been obliged to lay aside the instrument. Mr Cutbush of Philadelphia found that he could produce a spark in the dampest weather when he warmed the electrophorus before exciting it with a fox's tail, and kept the electrophorus box as tight as possible. As the cock is apt to become loose and allow the gas to escape, Mr Cutbush applied a mixture of tallow and finely pulverized plumbago to the cock; and, what is very curious, he found that the hydrogen gas prepared from zinc escapes much more readily than that procured from iron filings. He found that the former sometimes disappeared in twenty-four hours, while the latter often remained more than a week. The gas from iron filings is more impure than the other, from containing more or less carbon. With these precautions Mr Cutbush found that the lamp of Volta seldom disappointed him in producing flame. He ascertained that one cubic inch of gas will light the taper at least ten times if the cock is quickly turned.

Green's hydrogen lamp.

A hydrogen lamp acting by voltaic electricity in place of that of the electrophorus has been invented by Professor Jacob Green of Nassau Hall, and is quite independent of the state of the atmosphere. Its description, however, belongs to the subject of another article.

4. *Ronalds' Electrograph.*

Ronalds' electrograph. CCXXX., fig. 4.

M. Magellan had proposed to delineate the changes which take place in the electricity of the atmosphere, by a cylindrical and a plain electrograph. As our limits, however, will not permit us to describe these instruments, we shall content ourselves with giving a drawing and description of the more recent and useful electrograph invented by Mr Ronalds. This instrument is shown in fig. 4, where AA is a box with a strong time-piece placed horizontally, and moved by the weight B, and CC a disc of baked mahogany eight inches in diameter, with an aperture of $2\frac{1}{2}$ inches at D. The circumference of this disc, and also that of the perforation, are provided with edges or rims, and the outer broad rim is divided off and marked with hours and minutes like a common clock. The space between the two edges is almost filled with cement, composed of rosin, bees' wax, and lamp-black, and this part of the apparatus may be taken from the box at pleasure. A glass-tube EF, with brass caps, and covered inside and out with hard cement, screws by its lower end into the disc CC, while the upper end carries a small sheave, *g*. Within this tube EF a stem of glass is fixed by its lower end on the minute arbor of the time-piece, and a pivot attached to its upper extremity passes through F and the sheave *g*. This pivot carries the iron ball and cap *h*, into which is screwed the horizontal steel wire *i*, carrying the slider *k*, which moves with little friction along the wire. The piece *k* carries the vertical wire *l*, terminating below in a hook, upon which hook is hung a ring at one end of a short wire *m*, whose other end carries a small gold bead. A fine thread, *n*, is attached to *k* by one end, and by the other to the sheave *g*.

When the clock is going, its minute arbor carries round the arm *k*, and the effect of this is to coil the thread *n* round the fixed sheave *g*, and to make the piece *k* advance towards the ball *h*, so that the gold bead will trail upon the resinous disc CC, and describe a spiral upon it. If we now cause the little iron cap above *h* to communicate with a wire connected with any atmospherical conductor, the gold bead will electrify the resinous surface, so that when the plate is removed from the clock and powdered with pounded resin, or even dry hair powder, the spiral line will exhibit configurations varying in shape and in breadth according to the intensity and nature of the electricity which the resinous surface has received from the trailing bead. The times at which these phenomena take place will be shown by the dial-plate.

If this instrument is used for recording the phenomena of serene weather, dew, &c., the hour arbor should be used in place of the minute one; but if for those of a thunder storm, hard shower of rain, or hail, or snow, the minute arbor should be used. Mr Ronalds adds, that he has sometimes found a more rapid motion necessary, which can be obtained by the addition of a third arbor; the glass tube EF, with its appendages, being transferred to the most suitable arbor, and the disc adjusted to a new centre. Sheaves larger and smaller than *g* will be requisite for different applications of this electrograph.

5. *The Electrical Air Thermometer.*

This instrument, invented by Mr Kinnersley, is shown in fig. 5, where AB is a glass tube about ten inches long and two inches wide, having its ends closed by two air-tight brass caps, A and B. Through these caps slide two hooked wires, FG, EI, so that the small brass balls G, I, can be set at any distance, and an electrical spark passing between them may be made stronger or weaker as the occasion requires. Another small tube, HA, open at both ends, passes through a tube in the copper caps, and through this tube a sufficient quantity of mercury or water is introduced to fill the lower ends both of the wide tube AB and the narrow one HA. If an electrical charge is sent through the balls G, I when they are placed in contact, by connecting the hooks E, F with the outside and inside coating of a Leyden jar, no effect will be produced; but if the balls G, I are separated so that the charge passes in the form of a spark through the interposed air, the rarefied and displaced air will press on the surface of the mercury or water at the bottom of the tube AB, and raise it nearly to the top of the small tube HA. It will then sink after the explosion, and resume its former position.

Kinnersley's electrical air thermometer. CCXXX., fig. 5.

6. *Volta's Electrical Pistol.*

A brass vessel of a pear shape, or of an ellipsoidal form, being perforated at its two ends, a glass tube of the same diameter as the perforation is inserted in one of them, so as to extend to the centre of the ellipsoid, and to project about four inches beyond the vertex. Through this tube there passes a metallic stem, which is furnished with a brass ball at its outer end, while its other extremity reaches beyond the inner end of the glass tube. A mixture of equal parts of hydrogen gas and atmospheric air having been introduced at the second aperture, this aperture is closed tightly with a cork. The operator now grasps the ellipsoid by its equator, and when a spark is taken by its brass ball from the prime conductor, the gaseous mixture will instantly be exploded, and drive out the cork with a smart explosion. In place of a mere perforation at the extremity of the ellipsoid, a barrel may be inserted, and by using a cylinder of cork for wadding, a ball may be discharged from the pistol.

Volta's electrical pistol.

7. *Ronalds' Electrical Pistol.*

Another form of the electrical pistol is shown in fig. 9, at BCF, forming a part of Mr Ronalds' electrical telegraph. The pistol has the form of a pear, and the brass rod and ball, in place of being a continuation of its axis, is inserted on one side, as shown at D. We have given a separate section of this pistol in fig. 6, where AB is the body of the pistol, which contains the inflammable gas, C the cork which is to be discharged, D the glass tube, G the brass

Ronalds' electrical pistol.

Fig. 6.

Electrical Apparatus Electrotypie. ball with a brass rod going down through the glass tube and extended a little beyond it, and E another little ball and rod fixed in the lower end of the pistol. When the spark is communicated at G, the gas will explode and discharge the cork.

8. *Ronalds' Electric Telegraph.*

Ronalds' electric telegraph. M. Cavallo suggested the idea of conveying intelligence by passing given numbers of sparks through an insulated wire in given spaces of time; and some German and American authors have proposed to construct galvanic telegraphs by the decomposition of water. Mr Ronalds, who has devoted much time to the consideration of this form of the telegraph, proposes to employ common electricity to convey intelligence along insulated and buried wires; and he proved the practicability of such a scheme by insulating eight miles of wire on his lawn at Hammersmith. In this case the wire was insulated in the air by silk strings; but he also made the trial with 525 feet of buried wire. With this view he dug a trench four feet deep, in which he laid a trough of wood two inches square, well lined both within and without with pitch, and within this trough were placed thick glass tubes, through which the wire ran. The junction of the glass tubes was surrounded with short and wider tubes of glass, the ends of which were sealed up with soft wax.

CCXXX., fig. 7. Mr Ronalds now fixed a circular brass plate, fig. 7, upon the seconds arbor of a clock which beat dead seconds. This plate was divided into twenty equal parts, each division being worked by a figure, a letter, and a preparatory sign. The figures were divided into two series of the units, and the letters were arranged alphabetically, omitting J, Q, U, W, X, and Z. In front of this was fixed another brass Fig. 8. plate, as shown in fig. 8, which could be occasionally turned round by the hand, and which had an aperture like that shown in the figure, which would just exhibit one of the figures, letters, and preparatory signs, for example 9, V, and Ready. In front of this plate was suspended a pith Fig. 9. ball electrometer, B (see fig. 9) from a wire C, which was insulated, and which communicated on one side with a glass cylinder machine, D, and on the other side with the buried wire. At the farther end of the buried wire was an apparatus exactly the same as the one now described, and the clocks were adjusted to as perfect synchronism as possible.

Hence it is manifest, that when the wire was *charged* by the machine at either end, the electrometers at both ends *diverged*, and when it was *discharged* they collapsed, at the same instant. Consequently, if it was discharged at the moment when a given letter, figure, and sign, on the lower plate, fig. 7, appeared through the aperture, fig. 8, the same figure, letter, and sign would appear also at the other clock; so that by means of such discharges at one station, and by marking down the letters, figures, and signs seen at the other, any required words could be spelt.

This is not the place to describe the method of using the telegraphic dictionary, but we may state, that the electrical pistol F, which passed through the side of the clock-case GG, had an apparatus H, by which a spark might pass through it when the sign *prepare* was made, in order that the explosion might excite the attention of the superintendent, and obviate the necessity of close watching. See Telegraph.

9. *Ronalds' Atmospherical Conductor, founded on a New Mode of Insulation.*

This conductor is shown in fig. 10. A glass pillar, A, passes through a circular piece of hard boxwood B, and also through the piece C, the sides of the perforations in these pieces being lined with thick leather. Nut bolts, D, D, pass through B and C, to secure the glass pillar in its place. Ronalds' atmospherical conductor. Fig. 10. The dotted part of the support is hollow. The glass is about one-fourth of an inch thick at the opening, and the upper part of it is coated with sealing-wax. A small spirit-lamp, E, with a single thread of cotton wick, and having a glass chimney, is placed beneath the open mouth of the glass pillar. The pillar terminates above with a strong brass socket carrying the ball F, which is perforated to admit the lowest joint of a long bamboo fishing-rod G G, gilt and inclined at an angle of about 45°. The strong bent wire H carries the upper part of a Volta's straw electrometer I, which rests upon the table M. The piece which supports the straws is entirely detached from the glass bottle I, being fixed to the arm H when the instrument is in use. The same piece carries a cone or funnel K. From the bent wire N, similar to H, a pair of wood charcoal balls are suspended, or instead of them the quadrant electrometer O, which serves to mark the higher electrical intensities, such as those of rain, hail, snow, and heavy clouds, which are too strong to be measured by more delicate instruments.

When this instrument is screwed upon a table in an upper room, and the fishing-rod thrust out of the window, it will be found highly useful for examining the usual atmospherical electricity of serene weather. If it is to be used in the open air the ball F is unnecessary, and the rod can be placed vertically in the brass socket. Two insulators of this kind may be used to sustain a wire if required.

(D. B.)

ELECTRIC TELEGRAPH. See Telegraph.

ELECTROTYPIE, Electro-Metallurgy, Electro-Plating, the art of taking exact copies of any object in copper, silver, gold, or other metal, or of covering objects with metallic surfaces, through the energy of voltaic electricity. This beautiful process now so extensively used in the arts for gilding, plating, multiplying plates for engraving, and forming solid articles in gold, silver, and other metals, appears to have been first put in operation by Mr Bessemer of Camden Town, London, to deposit copper on lead castings so as to produce antique heads in relief for mantel-piece ornaments. Mr Jordan, however, in this country, and Professor Jacobi simultaneously on the continent, appear to have been the first to have made the details of the process known to the public. The process itself is a very simple one. The cast, piece of plate, or other object wished to be covered with a metallic coating, after being properly prepared, is immersed in a solution of the metal we wish to be deposited on it, and is connected with the positive or zinc pole of the galvanic battery; the other pole of the battery terminating in a plate of the metal which is in solution, and also immersed in the metallic solution. The galvanic action decomposes the metallic solution; the metal is deposited in an equal layer all over the prepared cast or object, and the acid or agent which held the metal in solution being thus set free, reacts on the plate of metal at the negative pole, dissolving it, and thus keeping up the strength of the solution. Cyanide of potassium has been found by the Messrs Elkington to be the best agent for producing solution of the oxides of silver and of gold.

When the object to be plated or gilded is of metal it requires only to be extremely clean, which is done by boiling it in caustic potash, and then dipping it in aquafortis solution. If, however, it consist of a cast of plaster of Paris, or wood, of wax, &c., its surface must be rendered a conductor of electricity to render it susceptible of the deposition of the metal on it. It is therefore carefully but completely blackened by means of plumbago; but it has been found that dipping the object in a solution of phosphorus has the same effect. For further information see Voltaic Electricity.

ELEMI, a concrete resinous matter yielded by several different plants, chiefly of the natural order *Burseraceæ*, and imported from a variety of sources. The whole commercial and botanical history of elemi is very confused, but the following varieties of the drug are more or less met with in commerce:—

1. Elemi in flag leaves. This is a yellowish-white resin, with a pervading tinge of green. It comes in masses weighing from one to three pounds, wrapped up in the leaf of a palm or of some species of *canna*. Dr Pereira found that this is imported from Holland, and therefore concluded that it is the produce of some Dutch settlement. It may perhaps be brought to Holland from the Moluccas. The plant yielding it is not known, but it seems not improbable that it may be the produce of *Canarium balsamiferum*, Will., a species found in many parts of the East, including the Moluccas and Ceylon. The resin of the species as brought from Ceylon was found by Dr Christison and others to resemble elemi in its physical characters.

2. East India Elemi. This is a soft yellow resin, imported in bamboos; and, though called East India, does not appear to be produced in any part of Hindustan. This has been ascribed to *Canarium commune*, L., a widely distributed Eastern species.

3. Manilla Elemi. This does not seem to differ essentially from the last, except that it is imported in masses and not in bamboos. It is probably the produce of *Canarium commune*. In the Philippine Isles there is obtained from a tree which M. Baup believed to be *Canarium album*, and which is known as *Arbol a brea*, or pitch tree, a resin resembling elemi, which is got in such quantity as to be used for pitching ships. It is possible that this may form part of the Manilla elemi of commerce.

4. Brazilian Elemi. This is described by M. Guibourt as being of a yellowish-white, mixed with greenish points, and comes in cases containing two or three hundred pounds. It is almost certain that if any elemi comes from Brazil, it is the produce of *Icica Icicæriba*, DC., which exudes a balsamic resin like elemi; but Brazilian elemi is not now known in British commerce, though this at one time seems to have been the most common variety in trade.

5. Mexican Elemi. This kind has been imported of late years into this country. It is pale greenish-white; and, from the shape of some of the masses, seems to have been collected in a large reed or other hollow stem. Dr Royle received specimens of the plant known to yield this variety, and determined it to be a new species of *Elaphrium*, which he named *E. elemiferum*.

6. Common Lump Elemi. This is a dark yellow resin, with a strong turpentine odour, frequently containing pieces of dissimilar appearance. It comes from Hamburg and Holland, and is evidently a factitious substance, probably made up of portions of true elemi mixed with *thus* or common yellow resin, and flavoured with some volatile oil.

Elemi varies much in colour, consistence, and odour, according to its age and state of preservation. All the true varieties have more or less of an odour like that of fennel, sometimes mixed with that of lemons. Elemi softens with a gentle heat, and becomes adhesive. Boiling alcohol dissolves the whole of it except the impurities; the solution as it cools depositing an insipid crystalline white resin which has been called *elemine*. Bonastre obtained from elemi 60 per cent. of transparent resin, 12·5 of volatile oil, 24 of elemine, 2 of bitter extractive, and 1·5 of impurities. It is not known, however, which variety he examined.

Elemi was at one time much in use as a constituent of unguents, but is now little employed. The elemi ointment of the pharmacopœias is intended to represent the once famed Liniment of Arcæus; it is occasionally used to keep up the discharge from setons. The principal consumption of elemi is to make varnishes for coach painters. (D. M.)

ELEPHANT. See index to MAMMALIA.

The Order of the ELEPHANT in Denmark is an order of knighthood of the first distinction. Its origin has been referred to the time of Canute IV., who is said to have instituted the order in commemoration of one of the Danish crusaders having killed an elephant during an expedition against the Saracens in 1189. That the elephant was adopted at that remote period as an heraldic emblem seems probable; but it would appear that properly this order does not date further back than the year 1478, when it was instituted by Christian I. on the marriage of his son with a princess of Saxony. The decoration—which is attached either to a collar of gold, or to a watered blue riband—consists of a white enamelled elephant bearing a black tower. The chevaliers of this order have also a silver star of eight rays embroidered on a mantle of crimson velvet.

ELEPHANTA ISLE, called by the natives Gharipoor, a small island between Bombay and the mainland, about 5½ miles from Bombay. It is nearly 5 miles in circumference, and contains about 100 inhabitants, employed in the cultivation of rice, and in rearing sheep and poultry for the Bombay market. The island is nearly overgrown with wood, and contains several springs of good water. But it owes its chief celebrity to the mythological excavations and sculptures of Hindu superstition which it contains. Opposite to the landing place is a colossal statue of an elephant, cracked and mutilated, from which the island received from the Portuguese the name it still bears. At a short distance from this is a cave, the entrance to which is nearly 60 feet wide and 18 high, supported by pillars cut out of the rock: the sides are sculptured into numerous compartments containing various representations of the Hindu deities, but many of the figures have been defaced by the blind zeal of the Mohammedans and Portuguese. In the centre of the excavations there is a remarkable bust of the Hindu Triad, or three-formed god, namely, Brahma the Creator, Vishnu the Preserver, and Seva or Mahadeva the Destroyer. The heads are 6 feet in length, well cut, and the countenances, with the exception of the under lip, are handsome. The head-dresses are curiously ornamented; and one of the figures, that of the destroyer, holds in its hand a cobra de capella snake, whilst on the cap are, amongst other symbols, a human skull and a young infant. On each side of the Trimurti is a pilaster, the front of which is filled up by a human figure leaning on a dwarf, both much defaced. There is a large compartment to the right, hollowed a little, and covered with a great variety of figures, the largest of which is 16 feet high, representing the double figure of Seva and Parvati, named Viraj, half male and half female. On the right is Brahma, four-faced, on a lotus; and on the left is Vishnu. On the other side of the Trimurti is another compartment with various figures of Seva and Parvati, the most remarkable of which is Seva in his vindictive character, eight-handed, with a collet of skulls round his neck. On the right of the entrance to the cave is a square apartment, supported by eight colossal figures, containing a gigantic symbol of Mahadeva or Seva cut out of the rock. There is a similar chamber in a smaller cavern, with its walls covered with sculptures, which, however, can hardly be seen, owing to the rubbish with which the place is filled. This singular seat of Hindu superstition is said to have been dedicated to Seva, but it contains numerous representations of all the Hindu deities. It has, however, from time immemorial been forsaken by its priests or Brahmins; and it is not even the resort of pilgrims. Its only devotees are married women, who offer up their prayers here for an increase of their family. This place is a most wonderful monument of antiquity and superstition. The work must have been one of incredible labour; and there is not the least trace or tradition to indicate the time when this temple flourished, much less the period of its formation; yet it is a proof that the Brahmi-

nical religion must have flourished in India at a very remote period of antiquity. E. Long. 73.; N. Lat. 18. 57. (E. T.)

ELEPHANTIASIS, a chronic disease, chiefly affecting the legs and feet, which sometimes swell to an enormous size. It is characterized by the skin becoming thick, rough, and scaly; the eyes fierce and staring; and the perspiration highly offensive.

ELEPHANTINE, a small island of the Nile, opposite Syene. See EGYPT.

ELEPHANTINE, in *Antiquity*, an appellation given to the books in which the Romans registered the transactions of the senate, magistrates, emperors, generals, &c.: probably so called as being made of ivory.

ELEUSINIA, in *Grecian Antiquity*, a festival observed in honour of Ceres, by some states every fourth year, but by others every fifth. The Athenians celebrated it at Eleusis, a town of Attica; and hence arose the name.

Ceres, says Isocrates, wandering in quest of her daughter Proserpine, arrived in Attica, where some good offices were rendered her, which it is unlawful for those who are not initiated to hear. In return she conferred two unparalleled benefits, namely, the knowledge of agriculture, by which the human race is raised above the brute creation; and the mysteries, from which the partakers derive sweeter hopes than other men enjoy, both as to the present life and a future state of existence. It was the popular opinion that the Eleusinian goddesses suggested prudent counsel to their votaries, and influenced their conduct; and that the latter were respected in the infernal regions, and had precedence in the assemblies of the blessed, whilst the unhallowed were left in utter darkness, wallowing in mire, or labouring to fill a leaky vessel. The Athenians were solicitous to secure these advantages to their children, by having them initiated as soon as possible in the Eleusinian mysteries.

Ceres was supposed to be particularly attached to Eleusis and its vicinity, which contained various memorials of her presence and of her bounty; as, the well named *Callichorus*, by which she had rested, in the reign of Erechtheus; the stone on which she sat, named the *sorrowful;* the Rharian plain, where barley was first sown; and the thrashing floor and altar of Triptolemus, a herdsman whom she instructed in the culture of that grain, the use of which succeeded that of acorns. Her mysteries continued to possess a pre-eminence in holiness, and to be accounted as much superior to all other religious festivals as the gods were to the deified heroes. Even the garments worn at the solemnity were supposed to partake of the efficacy of the mysteries, and to be possessed of signal virtues. It was customary to retain them until they began to decay, and then to dedicate them in the temple, or to use them as swaddling clothes.

The mystic temple as it was called, provided by Pericles for the solemnity, created by its sanctity an awe only equalled by the astonishment which its beauty and magnitude excited in every beholder. The profane or uninitiated were forbidden to enter it upon any pretence. Two young Acarnanians, who happened inadvertently to mix with the crowd at the season of the mysteries, and to go in, were discovered and put to death. The chief priest, hierophant, or mystagogue, was taken from the Eumolpidæ, a sacred family which flourished at Athens, and derived its descent from Eumolpus, a shepherd and favourite of Ceres. He was enjoined to observe celibacy, and he wore a stole or long garment, and on his head a wreath of myrtle. The grand requisites in this priest were a full and sonorous voice, solemnity of deportment, magnificence, and strict decorum. Under him, besides many of inferior station, was the daduchus or torch-bearer, whose hair was likewise adorned with a fillet; the priest, who officiated at the altar; and the hiero-ceryx, or sacred herald. All these were very important personages. The latter was of a family which claimed the god Mercury, and Aglauros, the daughter of Cecrops, for its ancestors.

The secrecy in which the mysteries were enveloped served to enhance the idea of their importance, and to increase the desire of participation. It was so strict that no person was allowed even to name the hierophant by whom he had been initiated; whilst public abhorrence and detestation awaited the babbler, and the law decreed that he should die.

The Athenians suffered none to be initiated into these mysteries excepting such as were members of their city. This regulation, which compelled Hercules, Castor, and Pollux to become citizens of Athens, was strictly observed in the first ages of the institution; but after a time all persons, barbarians excepted, were freely admitted.

The festivals were divided into greater and lesser mysteries. The institution of the latter arose out of the following circumstance. Hercules, having passed near Eleusis while the Athenians were celebrating the mysteries, desired to be initiated. As this request could not be complied with, he being a stranger, and as Eumolpus was unwilling to displease him on account of his great power and the services which he had rendered to the Athenians, another festival was instituted without violating the laws; it was denominated *μίκρα*, and Hercules was solemnly admitted to the celebration and initiated. These lesser mysteries were observed at Agræ, near the Ilissus. The greater were celebrated at Eleusis, from which place Ceres has been called *Eleusinia.* In later times the lesser festivals were preparatory to the greater, and no person could be initiated at Eleusis without a previous purification at Agræ. This purification they performed by keeping themselves pure, chaste, and unpolluted during nine days; after which they came and offered sacrifices and prayers, wearing garlands of flowers called *ἱμερὰ*, and having under their feet *Δίος κωδίον*, *Jupiter's skin*, which was the skin of a victim offered to that god. The person who assisted was called *ὑδρανός*, from *ὑδώρ*, *water*, which was used at the purification; and those purified were called *μύσται*, *the initiated.* A year after the initiation into the lesser mysteries they sacrificed a sow to Ceres, and were admitted into the greater, and the secrets of the festivals were solemnly revealed to them.

This festival was observed in the month Boedromion or September, and continued nine days, from the 15th till the 23d. During that time it was unlawful to arrest any man, or present any petition, on pain of forfeiting a thousand drachmas, or, according to others, on pain of death. It was also unlawful for those who were initiated to sit upon the cover of a well, or to eat beans, mullets, or weazels. If any woman rode to Eleusis in a chariot, she was obliged by an edict of Lycurgus to pay six thousand drachmas. The design of this law was to destroy all distinction between the richer and poorer citizens. When the season approached, the mystæ, or persons who had been initiated only in the lesser mysteries, repaired to Eleusis to be instructed in the ceremonial. The service for the opening of the temple, with morning sacrifice, was performed, and the ritual was then produced from the sanctuary. It was enveloped in symbolical figures of animals, which suggested words compendiously, in letters with ligatures, the tops being huddled together, or disposed circularly like a wheel, and the whole utterly inexplicable to the profane. The case, which was called *petroma*, consisted of two stones exactly fitted; and the mysterious record, after being read, was closed up and replaced until a future festival. The principal rite was nocturnal, and confined to the temple and its environs. The mystæ waited without with impatience and apprehension. Lamentations and strange sounds were heard. Thunder pealed above these noises, and flashes of light and fire irradiated the gloom, rendering the darkness which followed more awful and sublime. The candidates for initiation were beaten by some invisible hand, whilst frightful apparitions, and monsters of a canine form, were presented to them,

Eleusinia. which filled them with apprehension and terror, and paralysed their energies. The scene then suddenly changed to one of a brilliant and agreeable character. The propylæa or vestibules of the temple were opened, the curtains withdrawn, and the hidden things displayed. They were introduced by the hierophant and daduchus, the former of whom revealed to them the mysteries. The splendour of illumination, the glory of the temple and of the images, and the singing and dancing which accompanied the exhibition, all contributed to soothe the mind after its recent agitation, and to render the wondering devotee tranquil and satisfied. After this inspection, or, as it was called, the *autopsia*, they retired, and others advanced. The succeeding days were employed in purification, in sacrifice, in pompous processions, and in spectacles, at which they assisted, wearing myrtle crowns. The second day was called ἅλαδε μύσται, *to the sea, ye initiated;* because they were commanded to purify themselves by ablution in the sea. On the third day sacrifices were offered, as also a mullet, and barley from a field of Eleusis. These oblations were called θύα, and were held so sacred that the priests themselves dared not, as in other sacrifices, partake of them. On the fourth day the votaries made a solemn procession, in which the καλαθίον, or *holy basket of Ceres*, was paraded in a consecrated cart, while on every side the people shouted χαίρε Δήμητερ, *Hail, Ceres.* After these followed women, called κιστοφόροι, who *carried baskets*, in which was sesamin, carded wool, grains of salt, a serpent, pomegranates, reeds, ivy boughs, and so on. The fifth was called ἡ τῶν λαμπάδων ἡμέρα, *the torch day*, because on the following night the people ran about with torches in their hands. It was usual to dedicate torches to Ceres, and contend who should offer the largest, in commemoration of the travels of the goddess, and of her lighting a torch in the flames of Mount Ætna. The sixth day was called Ἴακχος, from Iacchus, the son of Jupiter and Ceres, who accompanied his mother in her search after Proserpine, with a torch in his hand. From this circumstance the hand of his statue was furnished with a torch, and it was carried in solemn procession from the Ceramicus to Eleusis. The statue, with those who accompanied it, called Ιακχαγωγόν, was crowned with myrtle. In the way nothing was heard but singing and the noise of brazen kettles as the votaries danced along. The way through which they issued from the city was called ἱερὰ ὁδός, or *the sacred way*, the resting place ἱερὰ συκῆ, from a *sacred fig-tree* in the neighbourhood. They also stopped on a bridge over the Cephisus, where they derided those who passed by. After they had crossed this bridge, they entered Eleusis by a place called μυστικὴ εἴσοδος, or *the mystical entrance.* The seventh day was devoted to sports, in which the victors were rewarded with a measure of barley, that grain having been first sown in Eleusis. The eighth day was called Επιδαυρίων ἡμέρα, because Æsculapius on his return from Epidaurus to Athens was initiated by the repetition of the lesser mysteries. It became customary therefore to celebrate them a second time upon this occasion, in order that those who had not hitherto obtained the privilege might be lawfully initiated. The ninth and last day of the festival was called πλημοχόαι, or *earthen vessels*, because it was customary to fill two such vessels with wine, one placed towards the east, and the other towards the west; which, after the repetition of some mystical words, were both thrown down, and the wine spilt on the ground was offered as a libation.

The story of Ceres and Proserpine, the foundation of the Eleusinian mysteries, was both verbally narrated and represented in allegorical show. Proserpine was gathering flowers when she was stolen by Pluto; and hence the procession of the holy basket, which was placed on a car dragged along by oxen and followed by a train of females, some carrying the mystic chests, shouting *Hail, Ceres.* At night a procession was made with lighted torches, in order to commemorate the goddess searching for her daughter. A measure of barley, the grain which it was believed she had bestowed, was the reward of the victors in the gymnic exercises; and the proceedings at the temple had a reference to the legend. A knowledge of these things, from which the profane were excluded, formed the amount of what was communicated to the initiated; and the mode in which it was performed was skilfully adapted to the reigning superstitions. The operation was forcible, and the effect in proportion. The priesthood flourished as piety increased; and although the dispensation was corrupt, its tendency was not malignant. It produced sanctity of manners, an attention to the social duties, and a desire to be distinguished for what was then deemed virtue. (See Warburton, *Divine Legation of Moses demonstrated;* Gibbon, in his *Miscellaneous Works*, on Virgil's account of Æneas's Descent into the Shades; and Heyne's *Excursus*, in reference to the same subject.) Further details respecting the Eleusinia are given under the head MYSTERIES.

Eleusis. ELEUSIS, a city of Attica, four leagues from Athens, and close to the shore opposite the island of Salamis. Like most of the other cities of Greece, its origin is ascribed to various fabulous characters, and, among these, to Ogyges; a circumstance which at least proves it to be of the highest antiquity. In the earlier period of its history it seems to have been an independent state, and was even so powerful as to contest with Athens itself the palm of superiority. A considerable portion of its small territory was occupied by the plains of Thria, remarkable for their fertility, though the hopes of the husbandmen were not unfrequently disappointed from the blight of the south wind. To the west was the Campus Rharius, where Ceres is said to have sown the first seeds of corn; and on its confines was the field called Orgas, planted with trees consecrated to Ceres and Proserpine. The temple of Eleusis, sacred to Ceres and her daughter, was considered as one of the most beautiful productions of the genius of Greece. It is said to have been founded by Pandion II., and Clemens Alexandrinus places it even 120 years earlier, in the reign of Lynceus. Its position and riches naturally exposed it to the attacks of the enemies of Attica, and though defended by a strong fortress, it was seldom able to make any lengthened resistance. Cleomenes, king of Sparta, dared to violate its sacred precincts; but if we may believe the statements of the Athenians, he was soon overtaken by the just vengeance of the gods, and seized with a sudden fit of madness. The Persians burnt it to the ground after the battle of Platæa; but scarcely had they evacuated the confines of Greece, when the Athenians determined to rebuild it with even more than its original magnificence. Ictinus, the architect of the Parthenon, was ordered to draw up the plan of the new edifice. He adopted the Doric order of architecture, without the erection of pillars in front of the building. We know not whether he lived long enough to carry his plan into execution; but it was during the splendid administration of Pericles, and under the cultivated taste of Phidias, that the temple of Eleusis was completed in all its magnificence. The mystic cell was begun by Corœbus, but he lived only to finish the lower row of columns, with their architraves. Metagenes, of the district of Xypete, added the rest of the entablature and the upper row of columns. Xenocles of Cholargus built the dome on the top. A portico was long afterwards added by Demetrius Phalereus, who employed for that purpose the architect Philo. This magnificent structure continued to exist for many centuries, till the destructive hordes of Alaric completed its overthrow in the year 396. The city immediately disappeared on the destruction of the temple, which had been its ornament and principal support; and upon the site nothing is now found but a miserable village called *Lepsina*, amidst the ruins of the sacred edifice. But the coins of Eleusis are still com-

mon, and represent Ceres drawn by dragons or serpents. The inscription is ΕΛΕΥΣΙ, or ΕΛΕΥ, within a wreath of ears of corn.

ELEUTHERIA, in *Grecian Antiquity*, a festival celebrated at Platæa, in honour of Jupiter *Eleutherius*, or "the assertor of liberty," by delegates from almost all the cities of Greece. Its institution originated thus: After the victory which the Grecians under Pausanias obtained at Platæa, B.C. 479, over Mardonius the Persian general, an altar and statue were erected to Jupiter Eleutherius, who had freed the Greeks from the tyranny of the barbarians. It was further decreed in a general assembly of the Greeks, by the advice of Aristides the Athenian, that delegates from all the Greek states should assemble annually at Platæa to celebrate the Eleutheria, or festival of liberty. Every fifth year the solemnities were celebrated with contests in which chaplets were awarded to the victors. The annual festival at Platæa still existed in the time of Plutarch, and was celebrated thus:—At break of day the procession set out through the middle of the town, headed by a trumpeter who sounded a signal for battle; and it was followed by waggons loaded with myrtle boughs and garlands, by a black bull, and a number of free youths (slaves being excluded from the ceremony) who carried libations of wine and milk in large-eared vessels, with jars of oil and precious unguents; and the rear was brought up by the archon or chief magistrate of the city, who, though not permitted at any other time to touch a weapon or to wear a garment that was not white, appeared on this occasion with a sword in his hand and clad in a purple tunic, and also bearing an urn preserved for this solemnity in the city archive. When the procession arrived at the sepulchres of those who had fallen at Platæa, the archon, having drawn water from a neighbouring spring, first washed and anointed the monuments, and then sacrificed the bull on a pyre of wood; at the same time invoking Jupiter and Mercury, and inviting the souls of the heroes who had perished on the plains of Platæa to partake of the entertainment prepared for them. He then filled a bowl with wine, and pledged those who lost their lives in the defence of the liberties of Greece. (Plut. *Aristid.*; *Strabo*, ix.; *Paus.* ix.)

A festival of the same name was observed by the Samians in honour of the god of love. Slaves, also, on their emancipation, kept a holiday which they called *Eleutheria*.

ELEUTHEROPOLIS, an ancient episcopal city, situated in the south-western plain of Judæa, between Hebron and Askelon. It has been identified by Dr Robinson with the modern Beit-Jibrin, the Betogabra of Ptolemy and the Peutingerian Tables.

ELEVATION *of the Host*, in the Romish Church, that part of the mass in which the priest raises the consecrated wafer above his head for the people to adore.

ELEVATOR, in *Anatomy*, the name of several muscles, which serve to raise a part of the body, as the lip or the eye.

ELEVATORY, an instrument used in trepanning, for raising a depressed or fractured part of the skull.

ELEVE, a term purely French, denoting literally a disciple or scholar—from an Italian word signifying an apprentice. It was first applied by French writers to the pupils of painters; and afterwards to such as studied any other art under a master. In the Royal Academy of Sciences there were 20 élèves; and in that of Inscriptions, 10 élèves.

ELF, a fairy or hobgoblin; an imaginary being which our superstitious ancestors supposed to inhabit unfrequented places.

Elf-Arrows, the name given by the ignorant to the ancient arrow-heads formed of flint which are still found in Scotland, America, and several other parts of the world, under the belief that they were shot by fairies, and that cattle were thus sometimes killed.

ELGIN, a royal and parliamentary burgh of Scotland, and county town of Elgin or Morayshire, 64 miles north-west from Aberdeen. Pop. (1851) 6337. It stands about five miles from the sea, in a valley sheltered on the north and east by the wooded eminences of Quarrywood and Barnett Hill, and watered by the Lossie, a small river which winds round the town. The elegant villas in its outskirts, and round the village of Bishopmill, which may be almost called a suburb of the town, give it a fine appearance when approached from the south or east. The town, which is about a mile in length, is well paved and lighted, and plentifully supplied with water. It contains many handsome buildings, which, being built of the beautiful light-coloured sandstone of the district, have a fine appearance. The parish church is a handsome structure in the Corinthian style, with an elegant spire. Near it, in the centre of the street, is a fountain, which marks the site of the old jail. The other principal buildings of the town are Gray's Hospital, Anderson's Institution, museum, New Market Buildings, court-house, jail, Free Church, South Free Church, Catholic Chapel, Commercial Bank, Caledonian Bank, Trinity Lodge Rooms, &c.

The academy, which stands on the south side of the town, is one of the best in the north of Scotland. It is conducted by a rector who presides over the classical department, and several assistants who teach the subsidiary branches. Elgin likewise possesses an infant and several other schools. Gray's Hospital stands on an eminence at the west end of the town, and is a handsome edifice surmounted by a dome. The sum of L.20,000 was left for its endowment by Dr Gray. It was opened in 1819 for the reception of patients from the town and county, and the average number of patients in the house at one time is 35. Adjoining the hospital is the Lunatic Asylum, built and supported by voluntary contributions, and generally containing 20 or 30 patients. Anderson's Institution, for the support of the aged and the education of youth, is at the east end of the town. Its founder, General Anderson, H.E.I.C.S., who was a native of Elgin, bequeathed the bulk of his fortune, amounting to L.70,000, for the building and support of this splendid institution. It was opened in 1833. Above the northern front of the building is a group of statuary representing the founder in an attitude corresponding to his character. There are generally from 40 to 50 children, and about 10 aged people, in the institution. Attached to it is a free school with an average attendance of 200 scholars. The museum belongs to the Morayshire Scientific Association, which holds its meetings monthly in the building. The new market is a long range of building, with an entrance from the High Street, and another from South Street. Attached to it is a small theatre, which is open for apart of the year.

The ruins of the magnificent cathedral stand on the east of the town. It is described by Billings as "at once the most stately and the most beautifully decorated of all the ecclesiastical edifices of the country." It was founded in 1224, and destroyed by fire, according to Fordun, in 1270. The greater part of the present ruins are attributed to a date closely subsequent to this. It was again burnt, along with the canons' houses and a great part of the town, by the "Wolf of Badenoch," a natural son of King Robert II., in 1390. It was slowly rebuilt; a solemn agreement having been come to that each bishop should apply one-third of his revenue for this purpose till the completion of the building. In 1568, in the regency of the Earl of Murray, the lead was stripped from the roof by an order of privy-council, and shipped for Holland to be there sold. Being thus exposed to the weather, the interior rapidly decayed. In 1711 the great centre tower fell. The ruin is now carefully preserved by the Commissioners of Woods and Forests. Near the cathedral stands the bishop's town residence. The dean and canons' houses stood round about the cathedral, and some of them existed till very lately. The re-

mains of the monastery of the Grey Friars stands on the south side of the town. Of a similar monastery of White Friars on the north there is now no vestige. On the "Lady Hill" are the ruins of an ancient fortification, said to have been used as a hunting seat by one of the Malcolms; and also an elegant pillar erected to the memory of the last Duke of Gordon.

The trade of the town is chiefly connected with the weekly and other markets. A woollen manufactory gives employment to a number of hands, chiefly in making blankets, plaiding, shawls, and drugget. There are also large tan works, and an iron foundry. Elgin communicates by railway with the harbour at Lossiemouth, and along the line there is a considerable traffic. There are two newspapers published weekly in the town; and besides circulating libraries and book clubs, Elgin possesses also a mechanics' institute and a literary association. The places of worship are numerous. Besides the Established Church, there are two Free Churches, two United Presbyterian, one Independent, two Baptist, one Episcopalian, and a Roman Catholic. Of late years the town has extended considerably, and several new streets have been erected. Its municipal corporation consists of a provost, 4 bailies, and 12 councillors; and along with Banff, Cullen, Inverury, Kintore, and Peterhead, it returns one member to the imperial parliament.

By some historians the name of the town is said to have been derived from Helgy, a Norwegian chief, who in the ninth century overran Morayshire. Others derive the name from the Saxon *Hely*, holy, and *Dun*, a hill. It was the favourite residence of William the Lion and the two Alexanders.

ELGINSHIRE, or MORAYSHIRE. See MORAYSHIRE.

ELGIN MARBLES, the name applied to that matchless collection of ancient sculpture which was acquired by the British Museum from Lord Elgin. They are mostly basso-relievos and fragments of statuary which had adorned the Parthenon at Athens. The history of this collection may be thus shortly stated. It was in 1799 that the idea of such a collection first occurred to Lord Elgin, when he was appointed ambassador at Constantinople. Mr Harrison, an architect, suggested to him in the course of conversation, that though the public possessed everything requisite to give them a general knowledge of the remains of Athens, yet to artists nothing but the actual representation by cast could be of essential service. Lord Elgin accordingly entered into communication with government on the subject; but the important transactions in which the nation was then engaged prevented the government from embarking in the undertaking. When Lord Elgin met Sir William Hamilton in Sicily, he entered with him into a more minute examination of the feasibility of the scheme; and it appeared to them most advisable that his lordship should be accompanied by artists from Italy. He accordingly obtained permission from the king of the Two Sicilies to take with him Signor Lusieri, a painter of great reputation, then in the service of that monarch; and from Rome he obtained two architects, two modellers, and a figure-painter. In the summer of 1800 these persons reached Athens. At this period the French were in possession of Egypt, and the Turks felt little inclined to afford any facilities towards furthering the object which Lord Elgin had in view. They in fact did everything to thwart him; and his artists could only obtain admission to the Acropolis, for the purpose of taking drawings, on the payment of a large daily fee. When, however, our arms proved victorious in Egypt, a favourable change took place. The Sublime Porte showed an inclination to grant whatever our nation might think proper to ask; and Lord Elgin, availing himself of this opportunity, obtained, in the summer of 1801, firmans or warrants to the chief authorities of Athens, in which it was stated "that he might view, draw, and model the ancient temples of the idols, and the sculptures upon them, and make excavations, and *take away any stones* that might appear interesting to him." There was little difficulty after this permission had been granted; and as the Turks showed a perfect apathy in respect to the preservation of these remains, and indeed often wantonly destroyed them, Lord Elgin determined to remove as many as he could. In this way these noble remains of antiquity came into the possession of a British subject.

In 1811 an offer was made by Mr Perceval to purchase the whole collection for the nation, and the sum of L.30,000 was named as the price which the government was willing to give; but Lord Elgin considered this an inadequate compensation for the outlay occasioned in procuring the collection, and declined the proposal. In 1812 eighty more cases of architecture and sculpture were added, and also a collection of medals.

In 1815, however, Lord Elgin presented a petition to the House of Commons, in which he offered to make over the collection to the nation, on such conditions as it might seem just and reasonable to that assembly to recommend. Accordingly a select committee was appointed to examine into the affair, and after due consideration, and the examination of many witnesses, the committee came to the resolution of recommending the house to offer L.35,000 as a reasonable and sufficient price for this collection.

Thus were these noblest models which the genius of man has ever produced secured to the nation;—an acquisition invaluable in itself, and the more to be appreciated when we consider that the cultivation of the fine arts has contributed to the reputation, character, and dignity of every government by which they have been encouraged, and that they are intimately connected with the advancement of everything that is valuable in science, in literature, and in philosophy. No country certainly is better adapted than our own to afford an honourable asylum to these monuments of the school of Phidias, and of the wise administration of Pericles.

Further particulars are contained in the *Report from the Select Committee on Lord Elgin's Collection of Sculptured Marble, &c.;* and in the *Memorandum of the Earl of Elgin's Pursuits in Greece*, 4to, 1810.

ELI, the high priest of the Jews when the ark was in Shiloh. He was the first high priest of the line of Ithamar, Aaron's youngest son. Eli also acted as regent or civil judge of Israel after the death of Samson; this function devolving on the high priest in the absence of any person specially appointed to deliver and govern Israel. He is said to have judged Israel forty years; the Septuagint makes it twenty. The longer period probably comprehends the whole period of his administration both as high priest and judge.

Eli seems to have been a religious man, but having failed to repress the conduct of his sons, Hophni and Phinehas, the judgment of God was at length denounced upon his house, through the young Samuel. During an inroad of the Philistines the ark of God was captured, and Eli when he heard the news fell heavily from his seat and died. The ultimate doom upon Eli's house was accomplished when Solomon removed Abiathar (the last high priest of this line) from his office, and restored the line of Eleazar in the person of Zadok.

ELIAS LEVITA, a celebrated Jewish grammarian, was born in 1472, at Neustadt in Franconia. He was professor of Hebrew at Padua, Venice, and Rome, and died at Venice in 1549. His principal works are the *Masorah*, or *Traditio Doctrinæ*, Ven. 1538, and a *Chaldaic, Rabbinical*, and *Talmudic Lexicon*, January 1541. His merits are summed up by Simon when he says, "*Solus Elias Levita inter Judæos desiit nugari.*"

ELIJAH (*i. e. God-Jehovah*) is introduced to our notice like another Melchizedek, without any mention of his father or mother; and from this silence of Scripture much vain speculation has arisen. Some of the Rabbins supposed that he was *Phineas*, the grandson of Aaron; whilst others thought that he was an angel in human form. He is called a Tishbite, either from Tishbeh, a city beyond the Jordan; or from a Hebrew root signifying to convert or reform. He is first introduced as denouncing a drought for three years and a half, on account of the sins of Ahab and his people. As the denunciation took effect, the king sought to wreak his vengeance upon him as the cause of their sufferings. At the command of God, he hid himself by the brook Cherith, where he was miraculously fed by ravens, or, according to some commentators, although with needless scrupulosity, by merchants or Arabians, as the word may possibly be translated. For one year God miraculously provided for his bodily wants at Cherith; but the brook dried up. Again, at the command of God he withdrew to Zarephath, where, at the house of a widow woman who did not hesitate to divide her last meal with him, he and the household were preserved by the miraculous multiplication of their remaining food. During his stay in her house the prophet raised the widow's son to life. For three years and six months (James v. 17) the destructive famine had spread its deadly influence over the whole nation of Israel. Ahab was yet alive and unreformed, and Jezebel, his impious consort, was still mad upon her idols. At the command of God Elijah once again stood before Ahab. Wishing not to tempt God by going unnecessarily into danger, he first presented himself to good Obadiah, and afterwards to Ahab as he came forth to meet him. At the interview Elijah flung back upon the king the charge of troubling Israel, and offered to decide the controversy between God and Baal by a miracle from heaven. As fire was the element over which Baal was supposed to preside, the sending of fire to consume a sacrifice was chosen as the criterion of divinity. For the trial the people assembled at Mount Carmel; and Elijah, at his altar, confronted the priests of Baal. At the time of the evening sacrifice the controversy was settled; and seizing the opportunity, Elijah demands the execution of the priests of Baal. Ahab too lends his magisterial authority to the sentence, and it is willingly carried into effect by the people, who regard these false priests as the authors of their calamities. At the prayer of the prophet a cloud rises out of the Mediterranean, and rain descends upon the whole land. Impressed with the hope that God's miraculous actings at Carmel might penetrate and soften the heart of Jezebel, Elijah, strengthened from on high, accompanied Ahab to Jezreel on foot. Learning, however, that she was infuriated against him and sought to take his life, he fled from her presence. In the wilderness and at Mount Horeb his heart is touched and his petulancy corrected by the ministration of the angel of God, and by a fearful exhibition of His Divine power. Revealing Himself in the gentle accents of a still voice, Jehovah announces to him that he must go and anoint Hazael king over Syria, Jehu king over Israel, and Elisha prophet in his own place, ere death can put a period to his labours. Leaving the cave of Horeb (B.C. 906), Elijah now proceeded to the field where he found Elisha in the act of ploughing, and cast his prophet's mantle over him.

For about six years from this calling of Elisha, Elijah remained in privacy, probably labouring in the schools of the prophets, till God sent him again to pronounce judgments upon Ahab and Jezebel for the murder of Naboth. When Ahab seemed to be triumphing in the possession of his ill-obtained gain, Elijah stood before him, and threatened him in the name of the Lord, that God would retaliate blood for blood, that his seventy sons shall die, and Jezebel shall become meat for dogs. Elijah again retires from the history till an act of blasphemy on the part of Ahaziah, the son and successor of Ahab, causes God to call him forth. Ahaziah having met with an injury, sent to consult Baalzebub, the idol-god of Ekron, in regard to the issue of his sickness; but the angel of the Lord tells Elijah to go forth and meet the messengers of the king, and assure them that he shall not recover.

After twice consuming the bands of fifty whom Ahaziah sent out for his apprehension, he at length appeared before the king and repeated the denunciation. This was his last public effort to reform Israel. After a brief sojourn with the schools of the prophets, and having made a circuit from Gilgal to Bethel and thence to Jericho, while standing on the other side Jordan he was carried into heaven in the sight of Elisha and fifty of the sons of the prophets.

ELIOT, JOHN, the apostle of the North American Indians, was born in England in 1604. At Cambridge he distinguished himself in theology and languages; but having quitted the Established church he emigrated to America in 1631, and became pastor of an Independent church at Boston. He was finally established at Roxbury, and from this point he carried on his missionary labours. Before eight years had elapsed upwards of 500 Indians abandoned their savage life and settled peaceably on the lands allotted to them by the provincial government. Eliot also translated the Bible and several religious treatises into the Indian tongue, and wrote a number of English works. In addition to all his other labours, he held the pastoral charge at Roxbury till within two years of his death, which took place in 1690.

ELIQUATION (*eliquare, to melt*), in *Chemistry*, the operation of separating a more fusible substance from one that is less so, by means of heat sufficient to melt the one but not the other; as an alloy of copper and lead.

ELIS, or ELEA, in *Ancient Geography*, a country of the Peloponnesus, bounded N. and N.E. by Achaia, E. by Arcadia, S. by Arcadia, and W. by the Ionian Sea. In its extreme length, Elis included all the country lying between the small river Larissus which separated it from Achaia, and the Neda which divided it from Messenia.

Elis was originally divided into three districts, the largest of which, ἡ κοίλη Ἦλις, or Hollow Elis, comprised the country between the promontories Araxus and Ichthys; the second, called Pisatis, extended from Cape Ichthys to the Alpheus; and the third, known as Triphylia, lay between the rivers Alpheus and Neda. Hollow Elis, by far the largest and most valuable part of the country, was again subdivided into two parts; the Acroreia or mountain country lying on the southern slopes of Mount Erymanthus, and champaign country through which the Peneus flows. In its physical distribution Elis was regarded by some of the ancient geographers as forming part of Arcadia. The great mountain range which separates the two countries throws off numerous low spurs into Elis, which slope down gradually to the sea. These ridges form the basins of the rivers which drain the country and inclose the great plains that constituted the most fertile land of ancient Greece. The shore of the country is low and sandy; and as the rivers have no fall towards the latter part of their courses, they lose themselves in the flat country, forming thus fens and marshes, which during the heats of summer are peculiarly unhealthy. Sand-dunes have, in course of time, been thrown up by the action of the waves, over which the sea sometimes breaks, and in this way some extensive lagunes have come to be formed. The fish off the coast of Elis are extremely numerous during the summer months. At that time canals are cut between the lagunes and the sea, and the fish run into these canals, and are caught in vast numbers by the inhabitants. But these advantages are more than compensated by the countless swarms of gnats which are engendered in the marshes, and which render it almost impossi-

ble to live near the sea, especially in summer. Though Elis possesses no great natural barriers against invasion, it nevertheless suffered less by war than any other of the Greek states. This is to be attributed chiefly to the sacred character which attached to the country as the seat of the Olympic games. Secure in their exemption from the attacks of enemies, the inhabitants devoted themselves to commerce and the arts of peace; and thus when other parts of Greece were poor and depopulated, Elis continued rich and well-peopled.

Hollow Elis is a broad and fertile plain, watered by the Peneus and its tributary the Ladon, whose united stream forms the modern Gastuni. It is still as fertile as in the days of ancient Greece, and grows largely corn, cotton, and flax. One variety of the last called *byssus*, believed to have been introduced by the Phœnicians, was inferior only to that of Palestine. The wine of Elis was excellent, and Bacchus was held in high honour in the country. The rich pastures on the river banks were peculiarly favourable for the rearing of cattle and horses, the latter of which are celebrated in the *Odyssey*.

Pisatis is traversed by the Alpheus, and is separated from Hollow Elis by Mount Pholoë, a spur of Erymanthus. Its level lands are equally fertile with those of that district. By far the larger portion of Triphylia is occupied with offshoots from the mountains of Arcadia. It is separated from Pisatis by the river Alpheus, on whose banks were the temple of Olympic Jove, and the plain which witnessed the celebration of the Olympic games.

The original inhabitants of Elis were called Caucones, and seem to have sprung from a Pelasgic source. From traces of the worship of Venus in the city of Elis, it is believed that the Phœnicians had settlements in this country at a very remote period. The inhabitants of Elis first appear in history as setting out for the Trojan war under the title of Epæans. They are described by Homer as living at this time in a state of constant hostility with their neighbours the Pylians. At the close of the eleventh century B.C., the Dorians invaded the Peloponnese, and Elis fell to the share of Oxylus and the Ætolians. These people, amalgamating with the Epæans, formed a powerful kingdom in the north of Elis. After this many changes took place in the political distribution of the country, and from time to time individual cities such as Pisa rose into temporary importance. The result of all these vicissitudes was, that the country came at length to acknowledge only three tribes, each independent of the other. These tribes were the Epæans, Minyæ, and Eleans. Before the end of the eighth century B.C., however, the Eleans had vanquished both their rivals, and established an undisputed supremacy over the whole country. Among the other advantages which they thus gained was the right of celebrating the Olympic games, which had formerly been the prerogative of the Pisans. The attempts which this people made to recover their lost privilege, during a period of nearly two hundred years, ended at length in the total destruction of their city by the Eleans. So complete was its annihilation, that the very existence of Pisa was doubted even by some of the ancient geographers. From the time of this event, B.C. 572, till the Peloponnesian war, the peace of Elis remained undisturbed. In that great contest Elis sided at first with Sparta; but that power, jealous of the increasing prosperity of Elis, availed itself of the first pretext to pick a quarrel with it. At the battle of Mantinea the Eleans sided with the allies against the Spartans, who, as soon as the war came to a close, took vengeance upon them by depriving them of Triphylia and the towns of the Acroreia. The Eleans made no attempt to re-establish their authority over these places, till the star of Thebes rose in the ascendent after the battle of Leuctra. It is not unlikely that they would have effected their purpose had not the Arcadian confederacy come to the assistance of the Triphylians. In 366 B.C. hostilities broke out between them, and the Eleans were at first successful, but were soon overpowered, and their capital very nearly fell into the hands of the enemy. Unable without assistance to make head against their opponents, they applied for assistance to the Spartans, who invaded Arcadia, and forced the Arcadians to recall their troops from Elis. The general result of this war was the restoration of their territory to the Eleans, who were also again invested with the right of holding the Olympic games, of which they had been deprived. During the Macedonian supremacy in Greece Elis sided with the victors, but refused to fight against their countrymen. After the death of Alexander they renounced the Macedonian alliance. At a subsequent period they joined the Ætolian League, but persistently refused to identify themselves with the Achæans. When the whole of Greece fell under the Roman yoke, the sanctity of Olympia secured for the Eleans a certain amount of indulgence. The games still continued to attract to the country large numbers of strangers, until they were finally put down by Theodosius in 394, two years previous to the utter destruction of the country by the Gothic invasion under Alaric. In later times Elis fell successively into the hands of the French and the Venetians, under whose rule it recovered to some extent its ancient prosperity. By the latter people the province of Belvedere on the Peneus was called, in consequence of its fertility, "the milk cow of the Morea." The country has of late greatly declined from its former prosperity. The sea-coast is now almost uninhabitable from malaria.

ELIS, now *Kaloscopi*, the capital of the foregoing country, was situated on a hill overhanging the river Peneus, where it issues from the mountain passes that inclose the upper part of its course into the champaign country beyond. Elis was remarkable as being the only fortified town in the country of which it is the capital; the other towns and villages, as has been already remarked, being unwalled. The history of the town is so closely identified with that of its country, that a recapitulation is here unnecessary. It long maintained its place as one of the most splendid and populous cities of Greece, though no remains of its ancient magnificence are now visible. One of the most sumptuous of its public buildings was the gymnasium, in which it was necessary that all the athletes who intended to take part in the Olympic should undergo a month's training before they were allowed to compete. The history and topography of Elis will be found very fully discussed in Leake's *Morea* and Curtius's *Peloponnesos.*

ELISABETGRAD, or JELIZABETGRAD, a fortified town of South Russia, government of Kherson, on the Ingal, 140 miles N. of Kherson. It was founded in 1754, is regularly built, and has a large arsenal, hospital, and several churches. Including its four suburbs, it has a population of 12,496.

ELISABETPOL, JELIZABETPOL, or GANSHAW, a fortified town of Georgia, province of Tiflis, and 90 miles S.E. of the town of that name. It was formerly a place of considerable importance, but is now in a rather dilapidated condition; having still, however, several elegant mosques and other public buildings. Pop. (1848) 12,966.

ELISHA (*i. e. God the Deliverer*), the successor of Elijah, whose mantle he received at his translation. At the opening of his ministry he vindicated his claim to a divine mission by the division of the Jordan, and the destruction of the children who taunted him with the translation of his master. He next predicted the miraculous supply of water to the hosts of Jehoram and Jehoshaphat, which proved the destruction of the Moabites. His miracles, unlike those of Elijah, were generally miracles of mercy, as, for example, multiplying the widow's oil, raising the Shunamite's son, and healing the leprosy of Naaman. Having defeated the schemes of

the Syrian king, he escaped from the band sent to apprehend him, by smiting them with blindness, and leading them into the heart of Samaria (B.C. 892). After predicting the liberation of Samaria from siege, he next appears as predicting the death of Benhadad. Having anointed Jehu, he disappears from the sacred narrative, and at the advanced age of ninety, he is called to his rest. Jehu mourned at his funeral; and a dead body touched by his bones immediately started into life.

ELISION, in *Grammar* and *Prosody*, the cutting off or suppressing a vowel at the end of a word, for the sake of sound or measure, when the next word begins with a vowel.

ELIXATION, in *Pharmacy*, the extracting of the virtues of ingredients by boiling or stewing.

ELIXIR (Lat. *elixare, to boil, to seethe*), in *Medicine*, a tincture composed of several ingredients. In modern pharmacy elixirs are called compound tinctures. Elixir was also the name given by the alchymists to a liquor for transmuting base metals into gold, as also to a cordial which was reputed to possess rejuvenescent qualities.

ELIZABETH, queen of England, one of the most fortunate and illustrious of modern sovereigns, was born in the palace of Greenwich on the 7th of September 1533. She was the only surviving issue of the ill-starred union between Henry VIII. and Anne Boleyn, which barely extended over a space of three years. Anne was crowned at Westminster June 15, 1533, and was beheaded within the Tower of London May 19, 1536. The girlish beauty and vivacity of Anne Boleyn, with her brief career of royal splendour and her violent death, invest her story with a portion of romantic interest; but she does not seem to have possessed any solid virtues or intellectual superiority. The name of Elizabeth cannot be added to the list of eminent persons who are said to have inherited their peculiar talents and dispositions from the side of the mother. On the contrary, she closely resembled her father in many respects,—in his stout heart and haughty temper, his strong self-will and energy, and his love of courtly pomp and magnificence. Combined with these, however, there was in Elizabeth a degree of politic caution and wisdom, with no small dissimulation and artifice, which certainly does not appear in the character of "bluff King Harry." Early hardships and dangers had taught Elizabeth prudence and suspicion, as well as afforded opportunity in her forced retirement for the pursuit of learning and for private accomplishments. The period of her youth was an interesting and memorable one in English history. The doctrines of the Reformation had spread from Germany to this country; and the passions and interests of Henry led him to adopt in part the new faith, or at least to abjure the grand tenet of the papal supremacy. Anne Boleyn, by her charms and influence, facilitated this great change; and there is historical truth as well as poetical beauty in the couplet of Gray:

> "That Love could teach a monarch to be wise,
> And gospel light first dawn'd from Boleyn's eyes."

The Protestantism of England was henceforth linked to Elizabeth's title to the crown. She was in her fourteenth year when her father King Henry died. Her education had been carefully attended to, latterly under the superintendence of good Catherine Parr, the last of Henry's queens. The young princess was instructed in Greek and Latin, first by William Grindal, and afterwards by Roger Ascham, who has described his pupil in glowing terms as "exempt from female weakness," and endued with a masculine power of application, quick apprehension, and retentive memory. She spoke French and Italian with fluency, was elegant in her penmanship, whether in the Greek or Roman character, and was skilful in music, though she did not delight in it. "With respect to personal decoration," adds Ascham, "she greatly prefers a simple elegance to show and splendour." This last characteristic, if it ever existed, did not abide with Elizabeth. Her love of rich dresses, jewels, and other ornaments, was excessive; and at her death she is said to have had about 2000 costly suits of all countries in her wardrobe. Nor can it be said that even at the tender age of sixteen, when Roger Ascham drew her flattering portrait, Elizabeth was exempt from female weakness. After the death of Henry, the queen-dowager married the Lord Admiral Seymour, whose gallantries and ambition embittered her latter days. Seymour paid court to the Princess Elizabeth, and with the connivance of her governess, Mrs Ashley, obtained frequent interviews, in which much boisterous and indelicate familiarity passed. The graver court ladies found fault with "my lady Elizabeth's going in a night in a barge upon Thames, and for other light parts;" and the scandal proceeded so far as to become matter of examination by the council. Mrs Ashley and Thomas Parry, cofferer of the princess's household (afterwards patronized by Elizabeth), were committed for a time to the Tower, and Elizabeth underwent an examination by Sir Thomas Tyrwhit, but would confess nothing. "She hath a very good wit," said Tyrwhit, "and nothing is gotten of her but by great policy." The subsequent disgrace and death of Seymour closed this first of Elizabeth's love passages; she applied herself diligently to her studies under Ascham, and maintained that "policy" and caution which events rendered more than ever necessary.

The premature death of Edward VI. called forth a display of Elizabeth's sagacity and courage. Edward had been prevailed upon by the Duke of Northumberland to dispose of the crown by will to his cousin Lady Jane Grey. The two sisters, Mary and Elizabeth, on whom the succession had been settled by the testamentary provisions of Henry VIII., as well as by statute, were thus excluded. Mary's friends immediately took up arms; Elizabeth was asked to resign her title in consideration of a sum of money, and certain lands which should be assigned to her; but she rejected the proposal, adding that her elder sister should be treated with first, as during Mary's lifetime she herself had no right to the throne. Elizabeth then rallied her friends and followers, and when Mary approached London, successful and triumphant, she was met by Elizabeth at the head of 1000 horse—knights, squires, and ladies, with their attendants. Such a congratulation merited a different acknowledgment from that which Elizabeth was fated to experience. But the temper of Mary, never frank or amiable, had been soured by neglect, persecution, and ill-health; and her fanatical devotion to the ancient religion had become the absorbing and ruling passion of her mind. She was not devoid of private virtues,—certainly excelling Elizabeth in sincerity and depth of feeling; but her virtues "walked a narrow round;" and whenever the Romish Church was in question, all feelings of private tenderness, and all considerations of public expediency or justice, were with Mary as flax in the fire. The five years of her reign are perhaps the most un-English epoch in our annals.[1]

[1] Miss Lucy Aikin, in her *Memoirs of the Court of Elizabeth*, praises the magnanimity of Elizabeth in allowing Shakspeare's drama of *Henry VIII.*, in which the wrongs and sufferings of Katharine of Arragon are embalmed, to be publicly offered to the compassion of her people. We wish that this instance of magnanimity could be justly ascribed to the queen; but it seems certain that Shakspeare's Henry VIII. was not produced till after Elizabeth's death. No poet would have dared to hint at the death of the queen while she lived; and Cranmer's prophecy in the fifth act speaks of the death of Elizabeth and of her successor James. We have Ben Jonson's testimony as to Shakspeare's favour with Elizabeth,—

> ——— "Those flights upon the banks of Thames,
> That so did take Eliza and our James."

To escape from indignities and persecution at court, Elizabeth was suffered to retire, though carefully watched, to her house of Ashridge, in Buckinghamshire. Wyat's insurrection, prompted by the rumoured marriage of Mary with Philip of Spain, made her still more an object of suspicion and distrust, as the hopes of the Protestant party were on all occasions turned to Elizabeth. The young princess was taken from Ashridge and privately committed to the Tower. Her death was demanded by some of the bigoted adherents of the court, but Mary dared not and probably did not desire to proceed to this extremity; Philip, when allied to the English crown, interceded on behalf of the fair captive, and Elizabeth was removed to Woodstock, under care of a fierce Catholic, Sir Henry Bedingfield. Her extreme wariness and circumspection baffled every effort to entrap her. She conformed outwardly to the Catholic Church, opening a chapel in her house at Woodstock, and keeping a large crucifix in her chamber. This conformity was not unnaturally ascribed to dissimulation, but part was probably real. To the end of her life, Elizabeth retained a portion of the old belief. She had always a crucifix with lighted tapers before it in her private chapel; she put up prayers to the Virgin (being, she said, a virgin herself, she saw no sin in this), she disliked all preaching and controversy on the subject of the real presence, and she was zealous almost to slaying against the marriage of the clergy. She was anxious to retain as much as possible of the Catholic ceremonial and the splendid celebrations of the church festivals, which the ardent reformers would gladly have swept away, as had been done in Scotland. The Anglican Church was a compromise.

The wretched and inglorious reign of Mary terminated on the 17th of November 1558. Elizabeth heard the news of her accession at Hatfield, and she fell down on her knees exclaiming in Latin, "It is the Lord's doing, and marvellous in our eyes," words which she afterwards caused to be stamped on a gold coin, impressing on her silver coin another pious motto, "I have chosen God for my helper." All her perils were now passed. The nation received her with umbounded enthusiasm. Church bells were rung, bonfires blazed, tables were spread on the streets, the Protestants exulted with a holy joy.

Elizabeth was in her 25th year when she ascended the throne. She had been better disciplined and trained for her high trust than most princes, yet the difficulties that surrounded the English crown at this time might well have appalled her. The nation was struggling in a war with France, trade was much decayed, Calais had been lost, and England was distracted by religious divisions and animosities. All Catholic Europe might be expected to be arrayed against the Protestant Queen of England. Elizabeth, however, at once chose the better part for herself and the nation. Without waiting for the assembling of her first parliament, she ordered the church service to be read in English, and the elevation of the host to be discontinued. But before this could be known abroad, she had instructed the English ambassador at Rome to notify her accession to the pope. Paul IV., then pontiff, arrogantly replied, that England was a fief of the Holy See, that Elizabeth was illegitimate, and could not inherit the crown, and that she should renounce all her pretensions and submit to his decision. If Elizabeth had ever wavered as to the course she should pursue, this papal fulmination must have fixed her determination. Twelve years afterwards, a subsequent pope, Pius V., issued a bull releasing English Catholics from their allegiance to the queen, and formally depriving her of her title to the throne. But the thunders of the Vatican, like the threats of the Escurial, fell harmless on the English shores. The nation, under its firm monarch and her wise counsellors, Cecil, Bacon, Walsingham, Sadler, and others, pursued its triumphant course, while its naval and military glories were augmented beyond all former precedent. The government of Elizabeth and the public events of her reign will fall to be recorded in another part of this work, under the head of ENGLAND. Her first parliament passed the famous Acts of Supremacy and Uniformity, which struck directly at the papal power. All clergymen and public functionaries were obliged to renounce the temporal and spiritual jurisdiction of every foreign prince and prelate; and all ministers, whether beneficed or not, were prohibited from using any but the established liturgy. These statutes were carried out with considerable severity; many Catholics suffered death; but all might have saved themselves, if they had explicitly denied the right of the Pope to depose the queen. The Puritans and Nonconformists, on the other hand, were content to bear some portion of the burden of intolerance and oppression, from the consideration that Elizabeth was the bulwark of Protestantism. If they lost her firm hand they lost all; and the numerous plots and machinations of the Catholics against the queen's life showed how highly it was valued, and how precious it was to Protestant Europe. In the latter part of the queen's reign, her domestic and fiscal regulations were justly open to censure. The abuse of monopolies had grown to be a great evil; grants of exclusive right to deal in almost all commodities had been given to the royal favourites, who were exorbitant in their demands, and oppressed the people at pleasure. Elizabeth wisely yielded to the growing strength of the Commons, and the monopolies complained of were cancelled. The monarchy, though as yet arbitrary, and in some respects undefined, was still, in essential points, limited by law.

One great object of the Protestants was to secure a successor to the throne by the marriage of Elizabeth. The nearest heir was Mary Queen of Scots, a zealous Catholic, supported by all the Catholic states, and who had ostentatiously quartered the royal arms of England with her own, thus deeply offending the proud and jealous Elizabeth. The hand of the English queen was eagerly solicited by numerous suitors—by Philip of Spain, who was ambitious of continuing his connection with England, by the Archduke Charles of Austria, by Eric king of Sweden, the Duke of Anjou, and others. With some of these Elizabeth negotiated and coquetted for years; to Anjou she seems to have been attached; but her affections were more deeply touched, as Mr Hallam has remarked, by her favourite Dudley, Earl of Leicester. Her early resolution, and that which ultimately prevailed over her weakness or vanity, was, that she should remain single and hold undivided power. To a deputation from the Commons on this delicate subject, she emphatically said she had resolved to live and die a virgin queen: "and for me it shall be sufficient that a marble stone declare that a queen, having reigned such a time, lived and died a virgin." She appears often to have wavered in her resolution; and in her partiality for handsome courtiers and admirers, to have forgotten her prudence and dignity. Her partiality for Essex was undisguised—it was unhappy for both; and making Hatton chancellor because he could dance gracefully, was a bold but not unsuccessful achievement. Elizabeth's fits of rage were as violent as her fits of love. Her maids of honour sometimes felt the weight of the royal hand; and when Essex once turned his back on her, she appropriately dealt him a box on the ear. As a pendant to these *nugæ*, we may add, that Elizabeth swore strongly, decided and masculine oaths.

The feminine weakness and egregious vanity of Elizabeth, in the midst of so many masculine qualities of heart

And the tradition that the poet wrote his *Merry Wives of Windsor* by request of the queen, *who wished to see Falstaff in love*, is at least highly probable.

and intellect, have afforded matter for many chapters of garrulous chroniclers. Five years after she ascended the throne, she issued a proclamation against portrait painters and engravers, who had erred in expressing "that natural representation of her majesty's person, favour, or grace," that was desired by her loving subjects, and who were ordered to desist until some "special cunning painter" might be permitted to have access to the royal presence. The works of the unskilful and common painters were, as Raleigh relates, by the queen's commandment, "knocked in pieces and cast into the fire." A long account is given by the Scottish ambassador Melville, of certain interviews he had with Elizabeth when in her most gracious and pleasant mood. She shewed him "my lord's picture,"—a portrait of the unworthy favourite Dudley; she changed her dress every day, "one day the English weed, another the French, and another the Italian, and so forth," asking Melville which became her best; her hair, he says, was rather reddish than yellow, and curled naturally; she inquired whether the queen of Scotland or herself was of highest stature, and Melville answering that Mary was tallest, "then," saith she, "she is too high, for I myself am neither too high nor too low." Melville praised Mary's accomplishments as a musician and dancer, and Elizabeth contrived, as if by accident, that he should hear her play upon the virginals: "she inquired whether my queen or she played best; in that I found myself obliged to give her the praise." In the matter of the dancing, Melville was also able to answer, that Mary did not dance "*so high and disposedly*" as Elizabeth. Determined to show all her accomplishments, Elizabeth addressed the wary ambassador in Italian, which she spoke "reasonably well," and in German, which he says, was "not so good." These glimpses of the *woman* Elizabeth, contrast strangely with the *sovereign*, who, at Tilbury camp, rode from rank to rank of her army, bareheaded, with a general's truncheon in her hand, declaring to her soldiers that she was resolved to live and die amongst them in the midst and heat of the battle; and that she thought it "foul scorn that Parma or Spain, or any prince of Europe, should dare to invade the borders of her realms." Language and sentiments like these must have insured the destruction of the troops of Parma or Spain, even if the vaunted Armada had not been sunk by the English fire or scattered by tempests.

The darkest stain on the memory of Elizabeth is her treatment of Mary Queen of Scots. To have cut off Mary from the crown, settling it on her son, would have secured the Protestant succession. Her execution, though clamoured for by the English nation, was an act of cruelty peculiarly revolting, as well as indefensible in law, on the part of a female sovereign and kinswoman. And Elizabeth's affected reluctance to sign the death-warrant, her promptings to Sir Amias Paulet that he should make away with the captive queen (which the "dainty precise fellow," as Elizabeth termed him, refused to do), and her feigned grief and indignation after the event had taken place, constitute altogether a tissue of disgusting hypocrisy, as injurious to the reputation of Elizabeth as the deed itself.[1]

To the end of her life, Elizabeth affected all the airs of a coy beauty and coquette. Even her statesmen addressed her in a strain of fulsome adulation and semi-gallantry. She was the Gloriana of Spenser, the "fair vestal throned in the West," of Shakspeare, and the idol of all the lesser poets, as well as courtiers and politicians. She continued her gorgeous finery and rigorous state ceremonial, and was waited upon by applauding crowds whenever she went abroad. We have a graphic picture of her in her sixty-fifth year by a German, Paul Hentzner, who saw the queen on a Sunday as she proceeded to chapel. She appeared stately and majestic; her face oblong, fair but wrinkled; her eyes small, yet black and pleasant; her nose a little hooked, her lips narrow, and her teeth black. She had pearls with rich drops in her ears, wore false red hair, had a small crown on her head, her bosom uncovered, her dress white silk, bordered with pearls of the size of beans, a collar of gold and jewels; and thus arrayed, Elizabeth passed along smiling graciously on the spectators, who fell down on their knees as she approached, while a marchioness bore up her train; a bevy of ladies followed her dressed in white, and she was guarded on each side by fifty gentlemen pensioners, carrying gilt battle-axes. A few years afterwards we see the eclipse of this Eastern splendour and servility. Towards the end of March 1603, Elizabeth was seized with her mortal illness. She became restless and melancholy, refused medicine, and sat for days and nights on cushions, silent, her finger pressed on her mouth. When asked by Cecil who should succeed her on the throne, she characteristically answered, "My seat has been the seat of kings; I will have no *rascal* to succeed me." She afterwards, when speechless, joined her hands together above her head, "in manner of a crown," to signify, in answer to another interrogatory from Cecil, that she wished the king of Scots to be her successor. She expired on the 24th of March 1603. And thus calmly passed away the last of the Tudors, the lion-hearted Elizabeth. She was in the seventieth year of her age and forty-fifth of her reign—a period of brilliant prosperity and advancement, during which England had put forth her brightest genius and soundest philosophy, and attained to the highest distinction and glory among the states of Europe.

Horace Walpole has assigned to Elizabeth a place in his *Catalogue of Royal and Noble Authors*, and a list of thirteen productions, exclusive of letters and speeches, is attached to the queen's name. They consist chiefly of translations from the Greek, Latin, and French, with a sonnet printed during her own lifetime, and some prayers and meditations. The learning of Elizabeth is undoubted: it was considerable even in that age of learned ladies; but her style is stiff, involved, quaint, and full of conceits—the whole evincing rather a predilection for literary and scholastic studies than literary taste or power. (R. C—S.)

ELIZABETHAN Style, in *Architecture*, the name given to the impure architecture of the time of Queen Elizabeth and James I. It may be called a mixture of the worst forms of the Gothic and the Italian styles; but it nevertheless is capable of wonderful picturesqueness in general effect. Deeply embayed windows, long galleries, and fantastic gables, are its principal characteristics.

ELK, in *Zoology*. See index to Mammalia.

ELL (Lat. *ulna*), a measure used chiefly for cloth, and varying in length in different countries. The English and the Flemish ells were those most in use in Great Britain. The English ell is 45 inches, while the Flemish ell is only 27 inches, or $\frac{3}{4}$ths of a yard. In Scotland the ell is $37\frac{1}{5}$ English inches.

ELLESMERE, a market-town of Shropshire, hundred of Pimhill, 16 miles N.N.W. of Shrewsbury. It is so called from the beautiful lake or *mere* near which it stands; and consists of four main streets, with a handsome church. Pop. (1851) 2087, chiefly engaged in tanning and the making of malt, the barley grown in the vicinity being of excellent quality. The site of the ancient castle, of which

[1] There was something like personal vindictiveness in the feeling entertained by Elizabeth towards Mary. She hated her for her personal charms and graces, for her having presumed to quarter the royal arms of England, for her having a "fair son," and for her complicity in the Catholic conspiracies. But more than all perhaps must she have been provoked by the malicious letter written by Mary to Elizabeth, in which she reported certain alleged speeches of the Countess of Shrewsbury, charging the queen with licentious amours, physical defects, absurd vanity, folly, avarice, &c. (See Hume, note to chap. xlii.) The original letter in Mary's handwriting was seen a few years since by Prince Labanoff in the repositories at Hatfield House. It is such a letter as no woman (royalty apart) could have forgiven.

there are now no remains, is now used as a bowling green, and commands a rich and varied prospect. Market-day Tuesday. Ellesmere is connected with the Mersey by a canal which greatly facilitates its trade.

ELLICHPOOR, a town of Hindustan, in the territory of Hyderabad, or the dominions of the Nizam, and the principal place of a jaghire, or feudal possession of the same name. A stone wall sixty feet in height surmounted by battlements surrounds the town, which is of considerable size, and contains several bazaars and houses built of brick. The khan of Ellichpoor held his jaghire from the Nizam on military tenure, furnishing a brigade of two battalions of infantry, two thousand horse, and four guns; but a few years since the relations between the feudatory and his superior were seriously disturbed, and several actions took place between the troops of the two chiefs, which were attended with varied success. Tranquillity was at length restored by the sequestration of the district and its transfer to the British, with other possessions of the Nizam, as a provision for the support of the military contingent which that prince is bound by treaty to maintain. The town of Ellichpoor is distant 40 miles N.E. of Argaum, where the Duke of Wellington gained a brilliant victory over the Mahrattas in 1803. Lat. 21. 10., Long. 77. 36. (E. T.)

ELLIOT, *the Right Honourable* George Augustus, Lord Heathfield, was the youngest son of Sir Gilbert Elliot, Bart. of Stobbs, in Roxburghshire, and was born about 1718. He received the rudiments of his education under a private tutor, and at an early period of life was sent to the university of Leyden. Being designed for a military life, he was sent from thence to the celebrated *Ecole Royale du Génie Militaire,* conducted by Vauban, at La Fère in Picardy, where he laid the foundation of that scientific knowledge which he so conspicuously exhibited at the defence of Gibraltar. He completed his military course on the Continent by a tour, undertaken for the purpose of seeing in practice what he had studied in theory; and as Prussia was then the best model for discipline, he continued some time as a volunteer in the service of that state.

Mr Elliot returned in the seventeenth year of his age to Scotland; and was in the same year, 1735, entered as a volunteer in the 23d regiment of foot, in which he continued for upwards of a year. From the 23d regiment he went into the engineer corps at Woolwich, and made great progress in study, until through his uncle Colonel Elliot he was appointed adjutant of the second troop of horse grenadiers. With these troops he went upon service to Germany, and was present with them in a variety of actions. At the battle of Dettingen he was wounded. In this regiment he obtained the rank of captain and major, and afterwards purchased the lieutenant-colonelcy. On arriving at this grade he resigned his commission as engineer, which he had enjoyed along with his regimental rank, and quitted a branch of the service in which he had been actively employed very much to the advantage of his country. He received the instructions of the famous engineer Bellidor, and made himself completely master of the science of gunnery; and had he not so disinterestedly resigned his rank in the engineer department, he would long before his death have, by regular progression, reached the head of that corps. Soon after this he was appointed aid-de-camp to George II., and was distinguished for his military skill and discipline. In 1759 he quitted the second troop of horse grenadier guards, being selected to raise, form, and discipline the first regiment of light horse, which was called after him *Elliot's.* As soon as they were raised and formed, he was appointed to the command of the cavalry in the expedition on the coasts of France, with the rank of brigadier-general. After this he passed into Germany, where he was employed on the staff, and greatly distinguished himself.

During the peace he was not idle. His great talents in the various branches of the military art procured him ample employment. In 1775 he was appointed to succeed General A'Court as commander-in-chief of the forces in Ireland; but he did not continue long on this station, not even long enough to unpack all his trunks; for finding that interferences were made by petty authority derogatory to his own, he resisted the practice with becoming spirit; and not choosing to disturb the government of the sister kingdom on a matter personal to himself, he solicited to be recalled. The government acceded to his request, and, in a fortunate hour for the safety of Gibraltar, he was appointed to the command of that important fortress. The system of his life, as well as his education, peculiarly qualified him for this trust. He was perhaps the most abstemious man of the age, indulging himself neither in animal food nor in wine. He never slept more than four hours at a time, so that he was up later and earlier than most other men. He so inured himself to habits of hardiness, that the things which prove difficult and painful to other men were to him his daily practice, and rendered pleasant by use. It could not be easy to starve such a man into a surrender, nor possible to surprise him. The example of the commander-in-chief in a besieged garrison has the most persuasive efficacy in forming the manners of a soldiery. Like him, his brave followers came to regulate their lives by the most strict rules of discipline before there arose a necessity for so doing; and severe exercise, with short diet, became habitual to them from their own choice. The military system of discipline which he introduced, and the preparations which he made for his defence, were contrived with so much judgment, and executed with so much address, that he was able with a handful of men to preserve his post against an attack, the constancy of which, even apart from the vigour with which it was made, would have been sufficient to exhaust any common set of men. With perfect calmness he desisted from any premature attempts to destroy the works which it cost the enemy time, patience, and expense to complete; he deliberately observed their approaches, and, with the greatest discernment, seized on the proper moment at which to make his attack with success. He never spent his ammunition in useless parade or in unimportant efforts. He never relaxed his discipline from the appearance of security, nor hazarded the lives of his garrison by wild experiments. By a cool and temperate demeanour, he maintained his station for three years of constant investment, in which the whole powers of Spain were employed against him. All the eyes of Europe were on this garrison; and his conduct has justly exalted him to the most elevated rank in the military annals of his time. On his return to England, the gratitude of the British senate was as forward as the public voice in awarding him that distinguished honour which his merit deserved. Both houses of parliament voted a unanimous address of thanks to the general; the king conferred on him the honour of knight of the bath, with a pension during his own and a second life of his own appointment; and on the 14th June 1787, His Majesty advanced him to the peerage by the title of Lord Heathfield, Baron Gibraltar, permitting him to take, in addition to his family arms, the arms of the fortress which he had so bravely defended.

His lordship died on the 9th July 1790 at Aix-la-Chapelle, of a second stroke of the palsy, after having for some weeks preceding enjoyed tolerable good health and an unusual flow of spirits. His death happened two days before he was to have set out for Leghorn on his way to Gibraltar, of which place he had been once more appointed governor, in the prospect of an approaching war. He married Anne, daughter of Sir Francis Drake of Devonshire, and had by her Francis Augustus, by whom he was succeeded in his title.

ELLIOTT, Ebenezer, the *Corn-Law Rhymer,* was

born March 17, 1781, at Masborough, in the parish of Rotherham, where his father was employed in an iron-foundry. At school his education was thwarted by a constitutional nervousness, which prevented him from doing little more than merely learning to write, and which kept him aloof from his boyish companions. From his sixteenth to his twenty-third year he wrought with his father, who had become nominal proprietor of the foundry. He afterwards engaged in business in Sheffield on his own account, and after a failure in his first attempt he succeeded in realizing a competence. The last years of his life were spent at Argilt Hill, near Barnsley, where he died December 1, 1849. His principal works are, *Corn-Law Rhymes; Love, a Poem; The Village Patriarch; Poetical Works;* and *More Prose and Verse by the Corn-Law Rhymer*, 2 vols. His political poems are generally characterized by an athletic energy, and an almost morbid sense of wrong; but his domestic verses will always hold a distinguished place in the popular poetry of England.

ELLIPSIS, or Ellipse, in *Geometry*, an oval figure produced from the section of a cone by a plane which cuts both sides of it in an oblique direction. See Conic Sections.

Ellipsis, in *Grammar*, defect, omission; a figure of syntax by which one or more words are omitted; as,—the landscape I admire, for the landscape *which* I admire.

ELLIPTIC, pertaining to an ellipse.

Elliptic Turning. Wood and other substances are turned into an elliptic form by means of a chuck, which is applied on the common turning-lathe. This chuck is on the principle of the trammel, Plate XXIX. fig. 1. The grooves in the chuck are much wider than in the trammel, and the points of the chuck that correspond to C, D, of the trammel, fig. 1, remain fixed, and in one horizontal line; whereas in the trammel these are the points which are put in motion.

Illustration of the principle. If two straight lines, crossing each other, be drawn on a piece of transparent paper; if this transparent paper be laid upon a sheet of white paper, with two points marked on it; if the transparent paper be moved round, so that the cross lines shall travel over the two points, in like manner as the two points C, D, in the trammel, fig. 1, travel over the cross grooves of the trammel; and if the point of a pencil be held fixed, and touching the transparent paper, so as to leave a trace on the transparent paper when the paper is moved; then after the transparent paper has made a revolution, the trace left on it by the point of the pencil will be an ellipse. This method of describing an ellipse represents the action which takes place in the chuck for turning ellipses: the point of the pencil which remains unmoved is in the same situation as the turner's gouge; the transparent paper which receives the trace of the ellipse from the fixed pencil is analogous to the wood which is to be turned into the form of an ellipse by the fixed cutting gouge.

Description of the chuck. In fig. 2 the chuck is represented as fitted on a common turning lathe, of which A is the pulley of the mandrel, B and C are the sides of the frame supporting the pulley, P the rest, D the frame in which the rest slides, E, F the feet of that frame, I the nut and screw which serve to fix the rest, G, H are the continuation of the sides B, C. K is the elliptic chuck, with two grooves, through which the knobs of the slider pass. These knobs are connected by a strong bar of iron screwed into their ends; and on this bar of iron is seen the screw for fastening the board, to which is fixed the wood or other substance which is to be turned elliptically.

Fig. 3. shows the other side of the chuck, which in fig. 2 is turned towards the side of the frame C. N, in fig 3, is the board with the grooves which contain the slider O. In the middle of N is seen the end of the screw, which is fixed to the mandrel. The board N has a circular motion, being fixed on the axis of the mandrel, whilst the slider O, at the same time that it is carried round by the circular motion of N, is constrained to perform other motions by the grooves in N and by the groove in O, fig. 3, which slides on the ring M, fig. 4.

In fig. 4, L is a part of the side C of the mandrel frame, with the ring M fastened to it. On this ring the broad groove in the slider O, fig. 3, moves when the lathe is set agoing; and this groove is at right angles to the grooves in N, fig. 3, in which the knobs of O move. In fig. 4 it is seen that the centre of the ring M may be made to coincide with the centre of the spindle of the mandrel, in which case a circle is described. If the ring is fixed, so that the centre of the ring does not coincide with the centre of the mandrel, an ellipse is described by the wood screwed upon the bar of O in fig. 2; and the most eccentric ellipse that the machine describes is obtained when the mandrel is at the circumference of the ring. The centre of the spindle of the mandrel, and the centre of the ring M, are always in one immoveable horizontal line, and are analogous to the points C, D, of the trammel, fig. 1. In fig. 3 it is seen that the sides of the grooves may be brought nearer together by means of screws; so that the sliders and the cylindric ring may fit exactly to the grooves. The best elliptic chucks are made of brass. (See *Mechanical Exercises*, by Peter Nicholson, London, 1812.) (W. A. C.)

ELLIPTOGRAPH, an instrument for drawing ellipses. The trammel is an instrument which has long been known and used for describing ellipses. On the principle of the trammel Mr Farey constructed his elliptograph in a form much more commodious for drawing. Mr Farey's elliptograph is represented at Plate CCXXXI., fig. 5. The circle A slides between the two parallel rulers D, E. The circle B slides between two parallel rulers F, G, at right angles to the former. In this way, if a line joining the centres of the circles is made to revolve, M, the extremity of that line, will describe an ellipse in the same manner as the extremity E of the line CDE, fig. 1, does in the trammel. The elliptograph may be considered as a trammel, in which the pins C and D, fig. 1, are enlarged into the circles A and B, fig. 5. The pinion at K, fixed to one of the arms of the lower circle, acting on a rack screwed to the upper circle, serves to alter the distance of the centres of the circles A and B; and, by so doing, this pinion serves to vary the eccentricity of the ellipses which the instrument describes. When the centres of the circles A, B, coincide, the describing pen M draws a circle. When the centres are removed from each other, and on the circles being turned round, an ellipse is described by the pen; and when the distance of the centres is increased, the eccentricity of the ellipse is increased. When the pen is at the centre it describes a straight line, continually moving to and fro on that line when the circles are turned round. The two circles are fixed together by screws, and can only be made to slide the upper circle over the lower by the action of the pinion K. The pinion at L moves a rack, by which the describing pen M, which draws the ellipse, is brought nearer to the centre for the purpose of drawing a small ellipse, and removed farther from the centre of the ellipse when a large one is to be drawn. The size of the ellipse may be increased as far as the size of the instrument will admit. The pair of rulers D, E, are placed below the pair F, G, as is seen in fig. 6. The instrument, when used, is held upon the paper with the thumb and a finger of the left hand at the nuts N, O; and the circles are moved by applying the right hand to the pins *f*; the pen M, pressing by its weight on the paper, then describes the ellipse.

Fig. 7 shows H, the socket for the compasses, with the centre pin on which the socket moves; and the pinion L and rack *h*, for moving along the frame *g* between the bars; and the other pinion K, for separating the circles.

The ruler P has two points, to fix the instrument to the paper. The ruler is united to the frame by screws, which serve to adjust the position of the instrument after the ruler has been fixed to the paper.

By means of the elliptograph any ellipse can be described, of which the long and short axes are given, provided it does not exceed the size of the instrument. When an ellipse is to be described, draw on the paper the longer and shorter axes, bisecting each other; place the instrument on the paper, so that the centre of the four rulers appears to coincide with the centre or the intersection of the two axes of the ellipse; and fix the instrument in this situation by the points that go into the paper. By the pinion L move the pen to one extremity of the short axis of the ellipse; turn the circles half round, to see if the pen comes to the other end of the short axis; if it does not, adjust the error one half, by moving the pen by the pinion L, the other half by moving the frame on the paper; continue this adjustment till the pen, setting out from the one end of the short axis, arrives in a half revolution at the other end. Next, by means of the pinion K, bring the pen to one end of the long axis of the ellipse; turn the circles half round, and if the pen reaches the other extremity of the long axis of the ellipse, the instrument is rectified; if not, one half of the error is to be corrected by moving the circles by means of the pinion K, and the other half by moving the instrument to a side on the paper, by means of the nuts N, O. The instrument is now adjusted; and the pen, resting on the paper, traces the ellipse required when the circles are turned round by the handles.

Mode of using the instrument.

Elliptograph for engraving.

An instrument similar to the elliptograph has been employed for engraving ellipses on copper plates, and for dividing these ellipses accurately, so as to give the perspective representation of a circle divided into equal parts, both in the case where the distance of the eye is limited, and in the orthographic projection. The Society for Encouraging Arts rewarded Mr Farey with their gold medal for his invention, and a description of the elliptograph is contained in the thirty-first volume of the Transactions of that society. (W. A. C.)

ELLORE, in Hindustan, in the British district of Masulipatam, presidency of Madras, a town with a military station, situated on the Jummalair, a torrent which about 3 miles below falls into the Colair Lake. The town is populous and well built; and the sides of the streets are planted with rows of trees affording grateful shade in a place where the heat is oppressive, the thermometer having been known to rise to 110° in the house, and to upwards of 120° in officers' tents. Lat. 16. 42., Long. 81. 10.

ELLRICH, a town in the Prussian province of Saxony, government of Erfurt and circle of Nordhausen, on the river Zorge, 45 miles N.N.W. of Erfurt. It has some paper and oil mills, and manufactures of linen and woollen goods. Pop. (1849) 2942. In the vicinity is the calcareous grotto of Kelle, 290 feet long, 260 broad, and 158 high.

ELM. See Planting, and Timber.

ELMACINUS, Elmacin, or Elmakyn, George, author of a *History of the Saracens*, and known in the East by the name of Ibn-Amid, was a Christian of Egypt, where he was born in the year of the Hegira 620, and of our era 1225. He occupied the place of ketib or secretary at the court of the sultans of Egypt, an office which was usually filled by Christians. His history consists of annals which extend from the time of Mohammed till the year of the Hegira 512 (A.D. 1117). It is principally occupied with the affairs of the Saracen empire, but contains some passages relating to the eastern Christians. In 1238 he succeeded his father Yaser Al Amid, who had held the office of secretary to the council of war under the sultans of Egypt for forty-five years. Elmacinus died at Damascus in the year of the Hegira 675 (A.D. 1273). His History of the Saracens was translated from Arabic into Latin by Erpenius, and printed in both languages at Leyden, 1625, in folio. Erpenius, however, died before the publication was completed; and the issuing of the volume was left to Golius, who wrote a preface to the work. The title is, *Historia Saracenica, quâ res gestæ Muslimorum, inde a Muhammede primo imperii et religionis Muslimicæ auctore, usque ad initium imperii Atabecæi, per XLIX. imperatorum successionem fidelissime explicantur, insertis etiam passim Christianorum rebus in Orientis potissimum ecclesiis eodem tempore gestis.* Arabice olim exarata a G. Elmacino et Latine reddita. Leyden, 1625, 8vo. The Latin text was printed separately in quarto; and there also exists an edition which only contains the Arabic text, and appears to have been designed for the Christians of the Levant. The work has been translated in whole or in part into several modern languages.

ELMINA, a town and fort on the Guinea Coast of Africa, capital of the Dutch possessions in that part. The fort is the strongest on the coast, being surrounded with double walls and deep ditches. Pop. about 10,000.

ELMSLEY, Peter, a distinguished philologist and editor, was born in 1773, and educated at Westminster and Oxford. After quitting the university he was appointed to a small chapelry at Horksley in Essex; but on the death of his uncle, from whom he inherited a competent fortune, he devoted himself to the study of Greek philology. He resided for some time at Edinburgh, where he lived in intimacy with the projectors of the *Edinburgh Review.* To this periodical he contributed the articles on Heyne's *Homer*, Schweighauser's *Athenæus*, Blomfield's *Prometheus*, and Porson's *Hecuba.* To the *Quarterly Review* he also contributed several classical articles. In 1819 he was commissioned along with Sir Humphry Davy to superintend the deciphering of the papyri at Herculaneum; and on his return after a short illness he was appointed principal of St Alban's Hall and Camden Professor of History at Oxford. He died of disease of the heart, March 8, 1825.

ELOGY, or Eulogy, (Lat. *elogium;* Fr. *éloge;*) eulogium, or the praise bestowed on a person or thing; panegyric. Among the French particularly it is a very general practice to pronounce *éloges* on illustrious deceased persons. To this custom the public has been indebted for many interesting biographical sketches.

ELOHIM, in Scripture, is the abstract expression for absolute *Deity*, apart from the special notions of unity, holiness, substance, &c. It is more a philosophical than a devotional term, and corresponds to our term *deity*, in the same way as *state* or *government* is abstractedly expressive of a king or monarch. Elohim is the plural form of *eloach;* and thus appears to be used as the *pluralis excellentiæ*—indicating the abundance and super-richness contained in the Divine Being.

The word Elohim was also sometimes applied to angels, princes, judges, &c., as indicating delegated authority.

ELOIGNED, or Eloined, (Fr. *esloigner*, q. d. *elongare, procul habere;*) removed to a distance; separated from;—a term used chiefly in law. Thus Blackstone—"If the person be conveyed out of the sheriff's jurisdiction, the sheriff may return that he is *eloigned, elongatus.*"

ELONGATION, in *Astronomy*, the digression or recess of a planet from the sun, as it appears to the eye of the spectator on our earth: the apparent recession of a planet from the sun in its orbit, as the *elongation* of Venus or Mercury.

ELORA, a town of Hindustan, in the native state of Hyderabad, near the city of Dowlatabad. In a mountain near this town there are some remarkable excavations, containing mythological symbols of the Hindu worship, and temples ornamented with representations and statues of many of the deities worshipped by the Hindus. The principal figures are those of Indra the god of the firmament, and his consort Indranee. Besides these, there are some figures of the deities adored by the sectaries of Boodh and

Parisinath; but all of them have been forsaken by the priests. The temples here are said to have been executed by the rajah Edoo of Ellichpoor, who was cured of some cutaneous disorders by a spring near the place, and in gratitude gave orders for the construction of the temple. It measures 138 feet in front, and in the interior extends 247 feet in length by 150 feet in breadth, and is in some places 100 feet high. A minute account of these curious antiquities is contained in the sixth volume of the *Asiatic Researches*. Elora was ceded in 1818 by Holcar, under the treaty of Mondesoor, to the British, who transferred it to the Nizam in 1822 by the treaty of Hyderabad. Lat. 20. 2., Long. 75. 13. (E. T.)

ELPHIN, a market-town and bishop's see of Ireland, county of Roscommon, and 14 miles N. of the town of that name. The cathedral is a plain building with an ancient tower. Pop. (1851) 1225.

ELPHINSTONE, WILLIAM, a Scottish prelate and statesman of considerable eminence, was born at Glasgow in 1431. He received his education at the university of that city, and in the learning which distinguished the period he made extraordinary proficiency. He afterwards studied civil and canon law in the university of Paris, where in due time he became professor, and for six years discharged the duties of his office with great reputation. On his return to Scotland he entered into holy orders, and was successively appointed official of Glasgow, St Andrews, and Lothian. He was also admitted a member of the privy-council; and on the occasion of a misunderstanding between James III. of Scotland and Louis XI. of France, his powerful mediation at the latter court, in conjunction with the Bishop of Dunkeld and the Earl of Buchan, effected an amicable reconciliation. For the diplomatic ability which Elphinstone on this occasion displayed, the king rewarded him with the see of Ross, from which he was translated to that of Aberdeen about 1484. He subsequently held the office of chancellor of the kingdom; and besides carrying on negotiations with the English king, he acted as mediator between James and the discontented nobility. During his residence at Aberdeen, Elphinstone appears to have declined all interference with public affairs of a political nature, and to have confined himself to the discharge of his episcopal duties. But when James IV. ascended the throne, his abilities as a statesman were again called forth, and he was chosen ambassador to the Emperor Maximilian, in order to negotiate a marriage between his royal master and the emperor's daughter. The bishop's mission, although it failed in the object for which it was set on foot, was not without its salutary effects, and was the means of terminating an enmity which had long existed between the Dutch and Scots. The masterly manner in which he conducted this affair raised him in the estimation of James, who undertook nothing of importance without first procuring his sanction. Elphinstone was also the zealous patron of learning; and it is generally believed that the establishment of a university at Aberdeen was entirely owing to his influence with the pope, from whom he obtained a bull for that purpose; and it was almost entirely by his exertions that King's College was undertaken and completed. At his death, which took place in 1514, he bequeathed a sum of 10,000 pounds Scots for its erection and endowment, as well as for the maintenance of a bridge over the Dee. Although at his death he had attained the age of about eighty-three, his constitutional vigour was very little impaired, and all the faculties of his mind were in full force; but the calamity which the nation sustained at Flodden Field had broken his heart. Besides a history of Scotland now preserved among the Fairfax MSS. in the Bodleian Library, Elphinstone wrote a book of canons and some lives of Scottish saints.

ELSINORE or ELSINEUR (Danish *Helsingör*), a sea-port-town of Denmark Proper, on the east coast of the island of Seeland. It stands at the narrowest part of the Sound, opposite the Swedish town of Helsingborg, from which it is three miles distant. The town is well-built, and contains some good buildings, among which are two churches, the town-hall, high school, hospital, theatre, and a quarantine establishment. Pop. (1850) 8111. On a tongue of land east of the town stands the castle and fortress of Kronborg (Crown Castle), the guns of which command the Sound in all directions. It was built by Frederick II. towards the end of the sixteenth century, and is a magnificent, solid, and venerable Gothic structure. The great tower, and the lighthouse which rises at the N.W. angle of the courtyard, command fine views of the strait and the neighbouring countries. The principal object of interest within the castle is the apartment in which the unfortunate Queen Matilda, sister of George III. was confined. All merchant vessels are obliged, under certain reservations depending on the weather, to salute the castle by lowering their top-sails in passing. In the vicinity is Marienlyst (Mary's delight), till lately a royal chateau, now the property of the corporation, and let to a private family. The pleasure-grounds are open to the public, and command fine views. Elsinore is 26 miles from Copenhagen, with which in summer it has steamboat communication twice a-day. All merchant ships passing the Sound have to clear out at Elsinore. The Sound duties had their origin in an agreement between the king of Denmark and the Hanse towns, by which the former undertook to construct lighthouses, landmarks, &c., along the Cattegat, and the latter to pay duty for the same. The annual amount of the Sound dues may be computed in round numbers at L.230,000. The average number of vessels that passed the Sound in the ten years from 1843 to 1852 was 18,088, and of British 4900; the greatest number of vessels in one year was in 1847, 21,526, and of British, in 1849, 6846. Ships of war are exempt from duty. Most maritime nations have consuls here. Elsinore is well known as the scene of Shakspeare's tragedy of Hamlet. It was the birthplace of Saxo-Grammaticus, the celebrated Danish historian of the twelfth century, from which Shakspeare derived the materials of his drama.

ELTHAM, a parish, formerly a market-town of England, county of Kent, 8 miles E. by S. of London. Pop. (1851) 1207. Of the royal palace which formerly existed here, only the great hall now remains. The parish church is a neat structure, and contains some interesting monuments.

ELVAS, a fortified frontier city of Portugal, province of Alemtejo, 12 miles west of Badajos. Pop. 16,460. It is picturesquely situated on a hill between two others on which stand the fortresses of Santa Lucia and La Lippe. The town is generally ill-built and dirty, while the number of Moorish buildings give it an antique and venerable appearance. The chief edifices are the cathedral, arsenal, bomb-proof barracks for 6000 or 7000 men, theatre, prison, public hospital, college, seminary, and a singularly formed tower. The town is supplied with water by means of a large Moorish aqueduct. Manufactures—hardware and jewellery; but many of the inhabitants depend on the contraband trade carried on with Spain. This was a place of great importance during the Peninsular war. It was taken by Marshal Junot in March 1808, and held by the French till the August following, when it was given up in terms of the convention at Cintra.

ELUTRIATION (*elutriare, to purify by washing*), the operation of diffusing an insoluble pulverulent substance in a large quantity of water, and, after the coarser particles have subsided, drawing off the supernatant liquid with a siphon, or by careful decantation. This liquor will be found to contain an impalpable powder, which is to be allowed to subside, and then taken out and dried.

ELY, a city of Cambridgeshire, capital of that division

of the county called the Isle of Ely. See CAMBRIDGESHIRE. The city stands on a considerable eminence near the Ouse, 16 miles N.N.E. of Cambridge. It consists chiefly of one long street, and the houses are mostly old. A monastery was founded here about 670; but in 870 it was pillaged and destroyed by the Danes, and was not rebuilt till about a century later. In 1107 Ely was erected into a bishopric by Henry I. After the dissolution of the monasteries Henry VIII. converted the conventual church into a cathedral. This edifice displays a singular mixture of various styles of architecture; but taken as a whole, it is a noble structure. The interior is exceedingly beautiful, and contains many interesting monuments. It has recently been almost entirely restored. The length of the building is 517 feet, and the western tower is 270 feet high. St Mary's church is a handsome building, partly in the Norman, and partly in the early English style of architecture. The church of the Holy Trinity, which is attached to the cathedral, was commenced in the reign of Edward II., and is one of the most perfect buildings of that age. Ely has also places of worship for Independents, Baptists, Methodists, &c.; a grammar-school founded by Henry VIII.; national, charity, and other schools; mechanics' institute, savings-bank, a house of correction, and infirmary. There is a considerable manufactory of earthenware and tobacco pipes, and there are several mills in the isle for the preparation of oil from flax, hemp, and cole-seed. Market-day Thursday. Pop. (1851) 6176. The soil in the vicinity is very fertile, and cultivated chiefly by market gardeners, who send large quantities of fruit and vegetables to the London market.

ELYSIUM, the place which, according to the ancient poets, the souls of the blessed inhabited. By Homer it was placed in the vicinity of Oceanus, and on the extreme confines of the earth. Here Nature produced her most delicious fruits without assistance from the hand of man. No winter storm ever obscured the brilliancy of the atmosphere; but cooling zephyrs refreshed the air, and wafted on their wings the most delightful perfumes. Admission into this realm of pleasure and repose was a favour which could only be purchased by an irreproachable life, or by brilliant exploits. The souls of the dead had to appear before the awful tribunal of the infernal judges, Æacus, Minos, and Rhadamanthus, who decided without appeal upon their claims, and either allowed them to pass into Elysium or condemned them to the torments of Tartarus. This part of the myth has evidently allusion to an Egyptian custom, according to which one could only obtain the right of burial in certain privileged cemeteries after undergoing a severe scrutiny of his life and conduct. It is curious to observe the various changes of position in respect to the Elysian Fields, as a more intimate acquaintance with geography successively dispelled the erroneous impressions derived from the foolish statements of travellers. The Greeks in the earlier ages placed them in the district of Thesprotia, where they also found the Acheron, Cocytus, and Avernus; and it was to this elysium that Homer tells us Mercury conducted the souls of the suitors of Penelope, after they had been slain by Ulysses. But they afterwards transported the Elysian Fields and Avernus to the vicinity of Baiæ in Campania.

> Largior hic campos æther et lumine vestit
> Purpureo; solemque suum, sua sidera norunt.

It was not till later times that these imaginary abodes were fixed at the extremity of Iberia, where they found the Lethe, "that slow and silent stream, the river of oblivion," now called *Guadalete*, as well as another of the same name in Lusitania.

ELYTRA (ἔλυτρον), in *Entomology*, the wing-sheaths or thick upper membranes which form the superior wings of the beetle tribe. They serve to protect the true membranous wing.

ELZEVIRS, celebrated printers at Amsterdam and Leyden, who produced many beautiful editions of the ancient classics. Their names were Louis, Bonaventure, Abraham, Lewis, and Daniel. Louis began to be famous at Leyden in 1595, and was remarkable for being the first who observed the distinction between the *v* consonant and *u* vowel, which had been recommended by Ramus and other writers long before, but never regarded. Daniel died in 1680, and though he left children who carried on the business, he is considered as the last of the family who excelled in printing.

EMANATION (*e* and *manare*, to *flow*), the act of flowing or proceeding from some source or origin. Also that which issues, flows, or proceeds from any source, substance, or body. Thus, light is an emanation from the sun; wisdom from God, &c.

EMANCIPATION (Lat. *emancipatio*), the act of setting free from slavery, servitude, subjection, or dependence; liberation from bondage or dependence, &c.

Emancipatio, in the *Roman Law*, was used in a special sense to denote an act by which the *patris potestas*, or the power of a father over his son, was dissolved in the lifetime of the parent. This end was effected by a certain formality in the manner of a *sale*—whence the term was derived. In some cases, according to the law of the Twelve Tables, this ceremony was performed three times; but in others once was sufficient, as it also was in the case of a daughter or a grandchild.

By emancipation the son was put in a capacity of managing his own affairs, and of marrying without his father's consent, although a minor. Emancipation differed from manumission, as the latter was the act of a master in favour of a slave, whereas the former was that of a father in favour of his son.

There were two kinds of emancipation; the one tacit, which was by the son's being promoted to some dignity, by his coming of age, or by his marrying—in all which cases he became his own master of course; the other express, where the father declared before a magistrate that he emancipated his son. In performing this act, the father executed an imaginary sale of his son to another person, who was called *pater fiduciarius*, or father in trust; from whom the son was immediately purchased by the natural father, who thereafter manumitted him before the magistrate by a verbal declaration. (For further details, see Smith's *Dict. of Greek and Roman Antiquities*.)

EMATHIA, in *Ancient Geography*, a central division of Macedonia, encircled on the north by the rivers Erigon and Axius, and on the south by the Haliacmon. It formed naturally a distinct and isolated country, comprising within its own limits all the elements of independence. The rivers and mountain ranges which begirt it on every side secured it against all attack from without, while its fertile plains, adorned with every variety of wood and water, formed the most important of its internal resources. Some of the strongest natural fortresses in Greece belonged to Emathia, such as Edessa and Berœa. It was in this country that the Macedonian dynasty, which ultimately subdued the whole of Greece, first began to develop itself.

Under the Romans Emathia formed part of the third region of Macedonia. Its principal cities at this time were Almopia, Atalanta, Berœa, Citium, Cyrrhus, Edessa, Europus, Gortynia, and Idomene. (See Leake's *Northern Greece*, vol. iii.)

EMAUM GHUR, in Scinde, was lately a strong fortress in the Thur or Great Sandy Desert, separating that province from the rajpoot state of Jessulmere. As scarcely a drop of fresh water can be had on the route from Scinde after leaving Choonkee, distant about fifty miles from Emaum

Phenomena and Laws.

appeared that electricity of exalted intensity passed through it, while it completely stopped voltaic electricity, confirms the observations of M. Delarive on the relation between the conducting power and the quantity of electricity which traverses the conductor; and the phenomena seem to indicate that the electric fluid or matter may consist, like solar light, of different parts possessing different powers of conductibility and other properties, which may facilitate or obstruct their passage through solid, fluid, or gaseous bodies. An electric current, composed of different currents, may have some of its component currents entirely stopped by some bodies, while other currents are transmitted with the greatest facility, in the same way as certain rays both of light and heat are entirely absorbed by coloured bodies, while other rays are copiously transmitted. Non-conductors, like black bodies, stop every electrical current. Perfect conductors, like colourless transparent bodies, may transmit every electrical current, or absorb a small portion of all of them in an equal degree; while there may be imperfect conductors, which, like coloured bodies, stop some currents and transmit others. If this should prove correct, two bodies which, when used separately, conduct electricity, would be insulators when joined so as to transmit the electricity in succession, in the same manner as two transparent coloured bodies which separately transmit light copiously are opaque when combined, the light which each transmits being absorbed by the other.

Absorption of electricity.

Distance to which electricity has been conducted;

We have already seen that electricity was conveyed through a distance of four miles. On the ground that these experiments were made imperfectly, and that an electric charge will prefer a short passage through air to a passage of twenty or thirty feet through thin wire, Mr Singers has expressed his conviction that the results of the experiments referred to are incorrect. We are unable, we confess, to appreciate the reasons on which this opinion is founded; but, even if they have any force, the original fact has been more than confirmed by Mr F. Ronalds, who erected at Hammersmith an electrical telegraph on which the inflections of the wire composed *one continuous length of more than* EIGHT *miles*. "When a Canton's pith-ball electrometer was connected with each extremity of this wire, and it was charged by a Leyden jar, both electrometers appeared to diverge suddenly at the same moment; and when the wire was discharged by being touched with the hand, both electrometers appeared to collapse as suddenly. When any person took a shock through the whole length of wire, and the shock was compelled to pass also through two insulated inflammable air pistols, one connected with each extremity of the wire, *the shock and the explosion seemed to occur simultaneously*. But when the shock was compelled to pass through the gas pistols, and any one closed his eyes, it was *impossible* to distinguish more than one explosion, although both pistols were discharged. When people did not look at the pistols, and when I sometimes charged only one highly, and sometimes both lowly, they could never guess, except by mere chance, whether one or both were fired. *Thus, then, three of the senses, namely, sight, feeling, and hearing, seemed to receive absolute conviction of the instantaneous transmission of electrical signs through my pistols, my* EIGHT *miles of wire, and my own proper person*."[1]

through telegraphic wires and submarine cable.

These results, interesting as they were some years ago, sink into insignificance compared with the extraordinary facts with which the operations of the electric telegraph have made us acquainted. The transmission of electricity through hundreds of miles of wire passing through the atmosphere, and through 300 miles of submarine wires stretching from Dover to Ostend, are facts familiar to everybody. Experiments have not yet been made to ascertain the distance to which a given electric force will pass through wires of different lengths and diameters, when insulated and uninsulated; but from the opportunities which we now possess from the extension of the telegraphic system, we may expect that very interesting results will ere long be obtained. The completion of the electric current, too, through immense distances in the ground and in water—as first noticed through distances of a few miles by Sir William Watson—is a remarkable fact which requires farther investigation in reference to Mr Lindsay's proposal of a transmarine telegraph.[2]

Velocity of electricity.

Various attempts have been made to measure or rather to estimate the velocity of electricity in passing along a conducting wire. Sir William Watson considered it to be less than any measurable portion of time in passing through a distance of 12,276 feet or 2⅓ miles, or as he expressed it, that it passed instantaneously through such a length of wire. The first attempt to measure the velocity of electricity by any accurate method, was made by Mr Wheatstone, who, by an ingenious apparatus, concluded that it moved along a copper wire at the rate of 288,000 miles in a second. According to the experiments of MM. Fizeau and Gonelli, it moves through a similar wire at the rate of 112,680 miles per second, and through an iron wire at the rate of only 62,000 miles. Professor Mitchell of Cincinnati found its velocity to be only 28,500 miles in a second; and Professor Walker of the United States only 16,000 miles through an iron wire. Along the copper wire between Greenwich and Edinburgh, its velocity was only about 6500 miles per second; and along the copper wire (a great part of which was plunged in water), between Greenwich and Brussels, only 2300 miles in a second. Dr Faraday ascribes the enormous differences in these measures, to a certain extent, to the influence of the conducting bodies in contact with the wire; and he is of opinion that the velocity may vary more than the hundredth of its velocity according as the electricity passes through a wire immersed in water, or through one suspended at a great distance from the ground, or one carried along a solid conducting wall. These experiments on the electric telegraph wires confirm, in a remarkable degree, the sagacious anticipation of Dr Faraday, who announced, at the time of the publication of Wheatstone's experiments, that *the velocity of electricity in the same metallic* would vary much "with the tension or intensity of the first urging force, which tension is charge and induction. So if the two ends of the wire in Professor Wheatstone's experiment were immediately connected with two large insulated metallic surfaces exposed to the air, so that the primary act of induction, after making the contact for discharge, might be in part removed from the internal portion of the wire at the first instant, and disposed for the moment on its surface, jointly with the air and the surrounding conductors, then I venture to anticipate that the middle part would be more retarded than before; and if these two plates were the inner and the outer coating of a large jar or a Leyden battery, then the retardation of that spark would be still greater."[3]

Experiments of Faraday.

These interesting anticipations have been proved by a series of fine experiments made by Dr Faraday with the telegraphic lines of wire between London and Manchester. This wire, which is 1400 miles long, is buried in the ground, and consists of four wires, each 350 miles long. At the Manchester station the extremities of the first and second wire were united, and also the extremities of the third and fourth. At the London station a galvanometer was attached to the end of the first wire, the ends of the second and third wire were united by a second galvanometer, and at the end of the fourth wire was attached a third galvanometer commu-

Embankment.

Previously to entering on the detail of the different descriptions of banks for the purpose of embanking, we shall here observe, that the pressure of still water against the sides of the vessel containing it being as its depth, it follows that a bank of any material whatever, impervious to water, whose section is a right-angled triangle, and the height of whose perpendicular side is equal to that of the water it is to dam out, will balance or resist this water, whatever may be the breadth of the surface of the latter; and therefore, that as far as width or extent is concerned, it is just as easy to exclude the Atlantic Ocean as a lake or a river of a few yards in width.

The earthen wall.

1. The Earthen Wall (Plate CCXXXI., fig. 1) is the simplest description of embankment, and is frequently erected by temporary occupiers of lands, on the general principle of inclosing and subdividing, which is sometimes made a condition of tenure between the landlord and tenant. This wall applies to lands occasionally but rarely overflowed or inundated, and is set out in a direction generally parallel to the river or shore. Its base is commenced on the surface from two to five feet wide, regularly built of turf on the outsides, with the grassy sides underneath. The middle of the wall is filled up with loose earth. The wall is carried up with the sides bevelled towards the centre, so as to finish in a width of one foot or eighteen inches at five or six feet in height. In the inside of such walls, and at the distance of three or four feet, a small open drain is formed, as well to collect the surface-water of the grounds within, as that which in time of floods will necessarily oose through a wall of this construction. The water so collected is let through the wall by tubes, or tunnels of boards, with a valve opening outwards on their exterior extremity. Such a tube and valve is represented by fig. 2. When the flow of water from without approaches, it shuts the valve, which remains in this state till the flood subsides, when, the height of the water within being greater than that without, it presses open the valve and escapes. Walls and valves of this kind were erected about the year 1800, on the estate of the Earl of Galloway near Wigton, by Mr Hannah, tenant for life of Cue farm, and by Mr Hutchinson, tenant for thirty years of Mersehead farm, on the Solway Frith. (*Farmer's Magazine.*) They are common enough in the drier parts of the fenny districts of Lincolnshire and Cambridgeshire; and in Caernarvonshire 1800 acres were in 1804 completely protected in this way on the estate of Tre Madoc, by the proprietor, who has since made greater efforts in embanking, to be afterwards described.

The earthen mound.

2. The Earthen Mound (fig. 3) is the most general description of embankment, and, as it is executed at considerable expense, is only undertaken by such as have a permanent interest in the soil. This barrier applies to sea lands overflowed by every spring tide, and to alluvial plains inundated by every flood. It is set out in a direction parallel to the shore and to the general turns of the river, but not to its minute windings; and it is placed farther from or nearer to the latter, according to the quantity of water in time of floods, the rapidity of the current from the declivity of the bed, the straight course of the stream, and the intended height of the bank. The two sides of such a mound are generally formed in different slopes. That towards the land is always the most abrupt, but can never be secure if more so than 45°; that towards the water varies from 45° to 15°; the power of the bank to resist the weight of the water, as well as to break its force when in motion, being inversely as its steepness. The power of water to lessen the gravity of bodies, or, in other words, to loosen the surfaces over which they flow or stand, is also lessened in a ratio somewhat similar.

The formation of such a mound consists merely in taking earth from the general surface of the ground to be protected, or from a collateral excavation, distant at least the width of the mound from its base line, and heaping it up in the desired form. The surface is then in general cases covered with turf, well rolled in order to bind it to the loose earth. The earth of such mounds is generally wheeled by barrows; but sometimes it is led by carts placed on a wooden roller instead of wheels, which, with the treading of the horses, serves in some degree to consolidate the bank.

The excavation within serves the same purpose as the open drain in the *earthen wall*, and similarly constructed sluices or valves are introduced on a larger scale. Sometimes also the interior water is drawn off by windmills, and thrown over the mound into the river. This is very common in Huntingdonshire, and might be greatly improved on by employing steam-engines for entire districts, one of which, of a ten-horse power, would do the work of twenty mills, and this in calm weather, when the latter cannot move.

Embankments of this description are the most universal of any, and their sections vary from a scalene triangle of ten feet in base and three feet in height, as on the Forth near Stirling, and the Thames at Fulham, to a base of 100 feet and a height of ten feet, as on the great bank of the Ouse, near Wisbeach. The great rivers of Germany and Holland are embanked in this way when so far from the sea as to be out of the reach of the tide; as the Vistula at Marienwerder, the banks of which, near Dantzic, are above fifteen feet in height; the Oder, the Elbe, &c. All these banks are closely covered in every part with a grassy surface, and sometimes ornamented with rows of trees.

But near the sea, where such banks are washed by every tide when the course of the wind is towards the shore, and by all land floods and spring tides, grass is only to be found on and near their summits. The rest of the bank is bare, and to preserve it from the action of waves, currents, and the stones, pieces of wood, and other foreign matters which they carry with them, the surface is covered with gravel, reeds, or straw, kept down by pieces of wood, faggots, wicker hurdles, nets of straw-ropes, or any other contrivance, according to the situation, to prevent the washing away of the bank. It is common to attribute to these coverings the power of breaking the force of the waves; but this power depends, as we have already stated, on the slope of the bank and its smoothness; and the use of the surface covering, and of the constant attention required to remove all obstacles which may be left on it by floods and tides, is to prevent the loosening power of the water from wearing it into holes. For this purpose, a sheet of canvass or straw-netting is as good whilst it lasts as a covering of plate-iron or stone pavement.

All banks whatever require to be constantly watched in time of floods or spring-tides, in order to remove every object, excepting sand or mud, which may be left by the water. Such objects, put in motion by the water, in a short time wear out large holes. These holes, presenting abrupt points to the stream, act as obstructions, soon become much larger, and, if not immediately filled up, turfed over, and the turfs pinned down, or the new turfs rendered by some other means not easily softened and raised up by the water, will end in a breach of the bank. A similar effect is produced by a surface formed of unequal degrees of hardness and durability. The banks of this description in Holland, at Cuxhaven, and along the coast of Lincolnshire, are regularly watched throughout the year; the surface protection is renewed whenever it goes out of repair, as is the body of the bank in the summer season.

Varieties of the mound.

Mound with puddle-wall.—It generally happens that the earth of such banks is alluvial, and their foundation of the same description; but there are some cases where the basis is sand, silt, or gravel, or a mud or black earth, as in some parts of Cambridgeshire and Lincolnshire, which does not easily become so compact. Here it is common, before beginning the bank, to bring up what is called a puddle-ditch, or section of clay, in the centre of the highest part of the mound in the direction of its length, and of three or five feet wide, according to the depth of the silt and the intended height of the bank. When the clay of this puddle-ditch is well worked, either by men's feet or clay rammers, the bank will be perfectly impervious to water, and, if against a mild stream or shore, need not contain such an accumulation of earth as where the imperviousness of the bank to water depends chiefly on the mass of materials. An important point to attend to in this variety of mound is, to found the section or wall of clay so deep as to be in contact with a stratum, either by induration or its argillaceous nature impervious to water.

Mounds with reversed slopes (fig. 4).—In some cases of embanking rivers, as where they pass through parks, it is desirable to conceal as much as possible the appearance of a bank from the protected grounds, less able to break the force of waves. Here the mound is simply reversed, the steepest side being placed next the water. It is proper to observe, that such banks are not so strong by the difference of the weight of the triangle of water which would rest on the prolonged slope were it placed next the river, and are more liable to be deranged in surface in proportion to the difference of the slopes.

Mound faced with stones.—This is the same species of mound, with a slope next the water of forty-five or fifty degrees, paved or causewayed with stones or timber. In Holland this pavement or causeway is often formed of planking or bricks; but in England generally with stones, and the mortar used is either some cement which will set under water, or, what is better, plants of moss firmly rammed between them. The objections to such banks are their expense, and their liability to be undermined invisibly by the admission of the water through crevices. They are, therefore, chiefly used where there is little room, or where it is desirable to narrow and deepen the course of a river.

Mound protected by a wicker hedge.—This is a Dutch practice, and, where appearance is no object, has the advantage of not requiring watching. Wicker-work, however, subjected to the strain of waves, will be obviously less durable than where it lies flat on the ground, and can only decay chemically. This wicker hedge is sometimes a series of hurdles supported by posts and struts; but generally in Britain it is a dead hedge or row of stalks wattled or wrought with bushes presenting their spray to the sea or river. Besides placing such a hedge before a bank, others are sometimes placed in parallel rows on its surface; the object of which is to entrap sand, shells, and sea-weeds, to increase the mass of mound, or to collect shells for the purpose of carrying away as manure.

The sea wall (fig. 5) is an embankment formed to protect abrupt and earthy shores or banks of rivers, and consists of a wall, varying in thickness, and in the inclination of its surface, according to the required height and other circumstances. Belidor, in his *Traité de Hydraulique*, has given the exact curve which the section of such a wall ought to have in order to resist loose earth, and which is somewhat greater than what we have given in the figure referred to, where the earth behind the wall is supposed to be chiefly firm. Some fine examples of such walls, for other purposes, occur in the CALEDONIAN CANAL; and perhaps the finest in the world are the granite walls which embank the Neva at Petersburg, the construction of which may serve as an example of a river case with a foundation of soft bog earth. A space of the river, say 100 feet long, and twenty wide along shore, being inclosed by a double row of piles, and filled in with loam in the usual way, the water is pumped out, and the ground excavated about ten feet deeper than the margin of the bed of the river. Poles are then inserted nearly as close as they can be put in, and driven to their full length. When finished, this foundation occupies a breadth of from twelve to eighteen feet, generally fifteen. The tops of the piles are now cut level, and covered with planks, and on this is raised a mass of brick-work for five or six feet, sloping on both sides as it ascends towards the centre line of the wall. In the course of rising six or seven feet, it is narrowed to five feet, and is within five feet of the bed of the margin of the river. Here the granite facing begins in immense blocks, and is continued at a slope of fifteen degrees from the perpendicular, till it reaches the surface of the intended pathway. Here the wall from three feet is narrowed to an upright parapet eighteen inches wide; and at four feet of height it is finished in a projecting coping of Finnish granite. The voids on each side of the wall are now filled with earth, the pavement on the land side (generally narrow) completed, and the piles removed, and another length taken in to repeat the operation.

There is another mode, adopted in Petersburg, of building under water by driving the piles and cutting them over level with a machine, and then sinking caissons of brick-work. This mode, however, is unsuitable for sea walls in general, which ought to be founded as deep as possible, and at all events under the bed of the water. The motion of the Neva is so slow as hardly to render this worth attending to.

In Britain, such walls are fortunately rare; for in proportion as it is agreeable and flattering to self-love to protect or gain lands never before cultivated, it must be mortifying to be obliged to protect such as have long been subjected to agriculture, and where success can only be said to have a negative advantage.

Embankments for fixing drifting-sands, shells, or mud.—In several tracts of coast, the sea at ordinary tides barely covers a surface of sand, and these sands in dry weather, during high winds, are drifted and blown about in all directions. Great part of the north shores of the Solway Frith, of Lancaster Bay, and of the coast of Norfolk, is of this description. Mr Young, in his *Farmer's Letters*, informs us, that a considerable part of the county of Norfolk was drift-sand, even as far inland as Brandon in Suffolk, before the introduction of the turnip culture; and Harte (*Essay I.*) states, that some of what is now the richest land in Holland was, about the middle of the sixteenth century, of this description. The suggestion of any mode, therefore, by which, at a moderate expense, such tracts could be fixed and covered with vegetation, must be deemed worthy of a place in this article.

The mode which nature herself employs is as follows: After the tides and wind have raised a marginal strip of sand as high as high-water mark, it becomes by degrees covered with vegetation, and chiefly by the *elymus arenarius*, *triticum junceum*, various species of *Juncus*, and sometimes by the *galium verum*. With the exception of the first of these plants (the leaves and stalks of which are made into mats and ropes in Anglesea and the Orkneys, and the grain of which is used as meal in Ireland), they are of no other use than fixing the sands, which, being composed in great part of the debris of shells, expand as they decay, and contribute to raise the surface still higher, when the fibrous roots of good grasses soon destroy the others.

To assist nature in fixing drift-sands, it is only neces-

sary to transplant the *elymus*, which is to be had in abundance in almost every sandy coast in Britain; and as it would be liable to be blown away with the sands if merely inserted in the common way, it seems advisable to tie the plants to the upper ends of *willow* or *elder* rods, of two or three feet in length, and to insert these in the sand, by which means there is the double chance of the grass growing, and the truncheon taking root. The elder will grow exposed to the sea breeze, and no plant throws out so many and such vigorous roots in proportion to its shoots.

The mode by which sands were fixed in Holland was by the formation of wicker work embankments, and by sticking in the sands branches of trees, bushes, furze, &c. in all directions. These obstructed the motion of the sands, and collected masses of sand, shells or mud, and sea-weeds around them, which were immediately planted with some description of creeping grass; or, what was more frequent, covered with a thin coating of clay, or alluvial earth, and sown with clover.

Though the most certain and least expensive mode of gaining such lands be undoubtedly that of seconding the efforts of nature, by inserting bushes, and planting the *elymus* in this way, yet it may sometimes be desirable to make a grand effort to protect an extensive surface, by forming a bank of branches, which might in a single or in several tides be filled with sand and shells. It is evident that such a bank might be constructed in various ways; but that which would be most certain of remaining firm, and effecting the purpose, would be one regularly constructed of framed timber, the section of which would resemble a trussed roof; each truss being joined in the direction of the bank by rafters, and the whole inside and surface stuck full of branches. To retain it firm, piles would require to be driven into the sand, to the upper parts of which would be attached the trusses. The height of such a barrier would require to be several feet above that of the highest spring-tides; and the more its width at base exceeded the proportion of that of an equilateral triangle the better.

A more economical mode, and one, therefore, suited to a less extensive scale of operation, is to intersect a sandy shore in all directions with common dead or wicker-work hedges, formed by first driving a row of stakes six or eight feet into the ground, leaving their tops three or four feet above it, and then weaving among these stakes branches of trees or the tops of hedges. The Dutch are said to weave straw ropes, and thereby to collect mud in the manner of *warping*. This mode being little expensive, seems to deserve a trial in favourable situations; and, in so doing, it must not be forgotten that much depends on the immediate management of the surface after it is in some degree fixed. In an extensive trial of this sort made on the west coast of Scotland, under an English gentleman, seeds and roots were kneaded in a mixture of loam and dung in the gravel, and then formed into masses, and scattered over a sandy surface. These, from their weight, will not, it is thought, be moved by the water or the wind; but becoming more or less covered with sand, the mass will be kept moist, and the seeds and roots will grow, and, fixing themselves in the soil, will in time cover the surface with verdure.

Embankments for straightening the course of rivers.—Where a river in a fertile valley is very circuitous in its course, land may be gained, and a more rapid efflux of the water produced, by straightening its course. The best plan in general for effecting this is, to find an entirely new bed or course for the river; otherwise, when it passes alternately through new soil and through a part of its old bed, its action on surfaces which are so different in regard to induration ends, if great care be not taken, in holes and gulleys in the new bank, which require to be constantly filled up with loose stones thrown in, and left to be fixed by the pressure and motion of the water.

The embankment used in straightening the course of rivers is almost always the mound with a clay wall in the centre, varying in width according to the depth of the different parts of the old bed of the river which it has to intersect. The materials for these banks are obtained from excavations for the new bed.

The pier called the *protecting pier* is to be considered as a species of embankment the object of which is to prevent the increase of partial breaches made in the banks of rivers, by accidental obstructions during floods. A tree or branch carried down by a stream, and deposited or accidentally fixed or retained in its banks, will repel that part of the stream which strikes against it, and the impulse, counteracted more or less by the general current, will direct a substream against the opposite bank. The effect of this continual action against one point of the opposite bank is to wear out a hole or breach, and the protecting pier is placed so as to receive the impulse of the substream, and reverberate it to the middle of the general stream. If this pier be not placed very obliquely to the substream, as well as to the general stream, it will prove injurious to the opposite bank, by directing a subcurrent there as great as the first; and, indeed, it is next to impossible to avoid this; so much so, that Mr Smeaton, in every instance in which he was consulted in cases of this sort, recommended removing the obstacle where that could be done, and then throwing loose stones into the breach. A perfect bed of a river would be a perfect half cylinder, and therefore we are decidedly of opinion that Mr Smeaton's mode is the best, as tending to maintain as much as possible this form. Mr Marshal (*Treatise on Landed Property*) has treated on piers of this description at considerable length; but a very little reflection will show that they are more likely to increase than to remedy the evil they are intended to cure. We have seen the injurious effects of such piers on the Tay and the Dee; and on a part of the Jed near Crailing they are so numerous that the stream is, to use a familiar phrase, bandied about like a football from one shore to the other; behind every pier an eddy is formed, and, if the stream does not strike it exactly, a breach in the bank. Many of these piers have in consequence been taken down.

The use of such piers can only be justified where the obstruction, from ill neighbourhood or some such cause, cannot be removed from the opposite bank; or where, as is sometimes the case, it arises from an island of sand or gravel thrown out by the river near its middle, and which, however absurd it may appear, the interested parties cannot agree as to who may remove it. The case of buildings also being in danger may justify such a pier for immediate protection; but if such breaches are taken in time, a few loads of loose stones will effect a remedy without the risk of incurring or occasioning a greater evil.

Such piers are frequently constructed of wicker work; either a mere wicker hedge projecting into the water, as is common where the rivers are of slow motion, as in England, and particularly on the Thames, Tame, and Severn; or a case of wicker work filled with stones, as is common where the motion is rapid, as in Scotland, and particularly on the Esk, Tweed, Tay, and Clyde.

Embankments to serve as roads are generally mounds without clay walls, carried through countries liable to be overflowed, without reference to protecting any part from water, through lakes or marshes, or across straits of the sea. The earth in such mounds is generally allowed to take its own slope on both sides, which is commonly from forty to forty-five degrees, and the width at top is

regulated by that of the intended road. The materials, when the mound is formed in a country merely liable to be overflown, as in many parts of Lincolnshire and Huntingdonshire, are excavated from ditches, or taken from the surface on each side of the mound. In Holland the roads formed on such mounds are bounded by rows of trees; a practice which it is to be regretted has not been more attended to in England, where accidents not unfrequently happen in the night, and particularly on the Boston and Wisebeach roads, both of which are formed in great part on such mounds, unprotected by hedges, rails, or trees. In passing through part of a lake, or strait, or marsh, the earth must of course be taken from the firm ground on the shores; and here the ground being generally soft below, the first operation is to lay a foundation three or four feet thick, of branches or faggots of copsewood, in order that the mound may sink in a body. The next thing, the direction of the mound being marked out by a line of poles placed along its centre, is to begin at one end, and wheel or cart on earth, throwing it down in the direction of the bank, raising it to its proper height and width, leaving the slopes at the sides to adjust themselves, either by the gravity of the material alone, or jointly with the loosening and spreading operation of the water.

The noblest attempt of this sort ever made in Britain was that of W. A. Madocks, Esq. in order to unite the counties of Merioneth and Caernarvon by a mound across an estuary and embouchure of the Glasslyn, two miles wide. Mr Madocks had, in 1802, succeeded in protecting from spring tides, by a wall or bank of the first species, 1800 acres of good alluvial soil, which he let at from 30s. to 50s. per acre; and his enterprising spirit induced him to contemplate the idea of gaining the whole bay or mouth of the stream, extending to nearly 4000 acres of alluvial and sandy earth, overflowed in great part by every tide. Besides the mere gaining of the land, this patriotic improver had another object in view; that of uniting two maritime points in two counties which at that time were separated by a day's journey; and, by effecting this, he would at the same time have rendered practicable a new line of road from Worcester along the top of this embankment, through a creation of his own, called the town of Tre Madoc, to the newly formed harbour of Porthdynlleyn, by which forty miles would have been saved to the public between Dublin and London, and fifty between Dublin and Bath.

After consulting various engineers, the first operation was begun in 1807, and consisted in forming an immense bridge of flood-gates in the solid rock of the shore, as such a bridge and gates could not be formed in any part of the mound. The use of this was to admit the exit of the river. This done, the mound was commenced from both shores, and rocky, sandy, and clayey materials thrown down in the direction of the mound, and left to take their own slope. The greater part of these materials consisted of argillaceous rock broken into small pieces, which being mixed with clay, the mound would have been of the strongest texture. As the work proceeded, an iron railroad was laid along the top of it, and extended to the quarries and excavations, by which means much labour was saved. In the course of three years the work was brought within fifty yards of meeting in the middle, but it was found extremely difficult to close it, from the rapidity of the influx and reflux of the tide. This difficulty, however, would have been overcome, and the proposed improvement effected at little more than the estimated cost, L.20,000, had not the various and extensive projects in which the proprietor was at that time engaged led him into pecuniary difficulties, which put an end to the undertaking, and, as is usual in such cases, called forth popular clamour against the plan. It is but just, however, to state, that the very plan now put in execution was contemplated about two centuries ago by Sir Hugh Middleton, who then wrote to a friend, that if he were not so deeply engaged in the scheme of bringing water to London, he should certainly engage in it. (See BEDFORD LEVEL.)

The writings of Smeaton, Young, Gregory, and others, contain the general principles on which is founded the art of embanking, and every other operation connected with water. (J. C. L.)

EMBARGO, an order issued by the government of a country to prevent the sailing of ships, either into or out of port, or both. Embargoes are usually imposed only in time of war, or under apprehension of invasion.

EMBASSY. See AMBASSADOR, and DIPLOMACY.

EMBATTLED, in *Architecture*, furnished with an indented parapet, or having the form of embrasures.

EMBDEN or EMDEN, a fortified seaport-town of Hanover, province of Aurich, and 12 miles S.W. of the town of that name. Though not the capital, it is the largest town in the province, and in 1848 contained 11,964 inhabitants. It stands on the Dollart; and although the harbour is shallow, the roadstead is capable of accommodating the largest vessels. The trade is considerable: in 1851, 435 vessels of the aggregate burden of 18,097 lasts entered, and 443 of 12,616 lasts left the port. The chief exports are corn, butter, cheese, tallow, honey, wax, wool, and hides; the imports—timber, hemp, potash, and French wine. The herring fishery, formerly considerable, has much declined, as indeed has also the town itself; for in 1652 it contained upwards of 20,000 inhabitants, and its trade was much more extensive than at present. Canals intersect the town in various directions, and also connect it with Aurich, the Ems, &c. Shipbuilding is carried on to a considerable extent, and there are also manufactories of linen and cotton goods, hosiery, hats, soap, leather, tobacco, and brandy. Among the principal public buildings are the town-house, a Roman Catholic and also a large Protestant church, the barracks, exchange, and custom-house. Embden has also a gymnasium, midwifery school, school of navigation, house of correction, deaf-mute institution, and a marine insurance society.

EMBER WEEKS are those in which the *ember* or *embring days* fall.

In the laws of King Alfred and those of Canute, these days are called *ymbren*, that is, circular days, from which the word was probably corrupted into *ember* days. By the canonists they are called *quatuor anni tempora*, the four cardinal seasons on which the circle of the year turns; and hence Henshaw takes the word to have been formed by corruption from *tempora*. The ember days are the Wednesday, Friday, and Saturday, after Quadragesima Sunday, after Whitsunday, after Holy-rood day on the 14th of September, and after St Lucia's day, 13th December; which four dates correspond generally with the four seasons of the year, spring, summer, autumn, and winter. It would appear that they were originally fasts, instituted in order to implore the blessing of the Almighty on the fruits of the earth; agreeably to which, Skinner supposes the word *ember* taken from the ashes or *embers* then strewed on the head.

EMBLAZONING. See BLAZONRY, and HERALDRY.

EMBLEM (ἔμβλημα, literally, that which is *put in* or *on*, something *inlaid*, from ἐμβάλλειν, to *cast in* or *insert*), in its ordinary acceptation, denotes a figurative representation which, by the power of association, suggests to the mind some idea not made evident to the senses; or, in other words, a figure or picture which represents one thing to the eye and another to the understanding. It has been otherwise defined as a kind of painted enigma, or a figure

representing some obvious history instructing us in some moral truth. Such is the image of Scævola holding his hand in the flames, and inscribed with the words "*Agere et pati fortiter Romanum est.*" The Greeks applied the term ἔμβλημα to inlaid or mosaic work, and also to all kinds of raised ornaments on vases, &c. The Romans too used *emblema* in the same sense. Thus Cicero, reproaching Verres with his plunder of statues and other works of art from the Sicilians, calls the ornaments upon them *emblemata*. It may be farther observed, that the Latin authors frequently compare the figures and ornaments of discourse to these *emblemata*. Thus, an ancient Latin poet, praising an orator, says, that all his words were ranged like the pieces in mosaic :—

> Quam lepide λέξεις compostæ, ut tesserulæ omnes,
> Arte pavimento, atque *emblemate* vermiculato.

The word emblem is now chiefly applied to a figure or representation intended to convey some moral or political instruction. Thus a balance is an emblem of justice; and in Scripture a white robe is an emblem of purity or righteousness. An emblem differs from a device in that the words of an emblem have a full and complete sense of themselves; while those of a device are significative only with reference to some particular person or thing. This difference will be more apparent by a comparison of the emblem above quoted with the device of a candle lighted, and the words *Juvando consumor*, "I am wasted in doing good."

EMBOLISM (ἐμβόλισμός, from ἐμβάλλειν *to insert*), intercalation; or the insertion of days, months, or years, in a cycle or period of time, in order to produce regularity. The Greeks made use of the lunar year of 354 days, and in order to adjust it to the solar year of 365 days they added a lunar month every second or third year, which additional month they called *embolimæus*, *i. e.* the inserted one. See CALENDAR.

EMBOSSING, the forming of works in relief upon any substance, whether by cutting, stamping, casting, or any other method. In sculpture particularly, according as the figures are more or less prominent, they are said to be in alto, mezzo, or basso-relievo; or high, intermediate, or low relief.

EMBRASURE, in *Architecture*, an opening in a wall splaying or spreading inwards. In fortification it is applied to the openings in the wall or parapet of a fortified place, or in the breastwork of a battery, through which the guns are fired.

EMBROCATION (ἐμβρέχειν, *to moisten*), any liquid applied externally to the body to reduce swelling or relieve pain.

EMBROIDERY (in French, *broderie*). To embroider signifies properly to surround with an edge or border, but more generally to adorn with figures of needlework. The art of embroidery was practised at a very early period. In Exodus we are told that Aholiab was "an embroiderer in blue and in purple and in scarlet and fine linen;" and long before the Trojan war the women of Sidon had acquired celebrity for their skill in this art. The Greeks ascribed the invention of it to Minerva, but it is probable that they derived their knowledge of it from the Phrygians. The Grecian women attained to such a degree of skill in this art, that their performances were said to rival the finest paintings.

Embroidery is wrought upon stuffs or muslin by means of a needle and various kinds of thread. When it is done upon stuffs, the threads are of silk, cotton, wool, gold, and silver; and the work is sometimes adorned with spangles, mock or real pearls, &c. This species of embroidery is wrought on a kind of loom or frame. In muslin embroidery the muslin is stretched on a pattern already designed, and the thread is of cotton. The modes of embroidering are extremely various, and a minute description of them would be uninteresting to the general reader.

According to the census report of 1851, the number of females so employed in England was 2521, and in Scotland 2071; while in Ireland, for which no returns have been made the number is vastly greater; one house in Glasgow alone affording employment to upwards of 3000 hands in that country. The introduction in 1834 of a machine, by means of which the most difficult patterns may be wrought with the greatest nicety by 130 needles all in motion at once, has considerably affected this art as a trade, and will doubtless in a great measure supersede it. As a description of this interesting machine could not be made intelligible without illustrations, we must refer to Ure's *Dictionary of Arts, &c.*

EMBRUN, the ancient *Ebrodunum*, a fortified town of France, capital of a cognominal arrondissement in the department of Hautes-Alpes, on a steep rock near the right bank of the Durance, 25 miles E. of Gap. Pop. (1851) 3201. Embrun was an important military station in the time of the Romans. In the time of Constantine it was the see of a bishop, and afterwards of an archbishop, which was suppressed at the Revolution. The principal building in Embrun is the cathedral, a handsome Gothic structure surmounted by a lofty tower.

EMBRYO (ἔμβρυον), in *Physiology*, the first rudiments of an animal in the uterus, before the several members are distinctly formed; after which it is termed a *fœtus*.

EMERALD, *Smaragdus, Schmaragd, Emeraude verte.* In mineralogy this includes two subspecies; the emerald properly so called, or the precious emerald—comprehending the transparent and beautiful green-coloured varieties—and the beryl, which has already been described under its appropriate head.

The emerald always occurs crystallized, its most common form being that of a regular six-sided prism, occasionally modified by truncations on the terminal edges. It is in general well characterized by that pure and lively green colour which has hence received the name of *emerald green;* its hue, however, varies somewhat, inclining at times to verdigris or grass green, and frequently becoming rather pale. This fine colour is occasioned by the presence of a minute portion of the oxide of chrome, to which indeed may be attributed the principal distinction between emerald and the beryl; the mountain-green and yellow colours of the latter being produced by an admixture of iron in different states of oxidation. The most magnificent crystals of emerald occur in veins of magnesian carbonate of lime which traverse a hornblende rock in the mine of Muso, near Santa Fé de Bogota, in Peru. A hexagonal prism from this locality, upwards of two inches in length, and measuring across its three diameters $2\frac{1}{4}$, $2\frac{1}{8}$, and $1\frac{7}{8}$ inches, is now in the possession of the Duke of Devonshire: it weighs eight ounces and eighteen dwts., and, though imperfect for the lapidary's purposes from the numerous flaws it contains, is unquestionably the finest crystallized emerald at present in Great Britain. There are some magnificent crystals of emerald in the Royal Collection at Madrid, some of them as large as those of the Duke's collection, and of the finest water. Less distinct varieties, generally of muddy emerald-green colours, occur imbedded in mica-slate in the Pinzgau valley, Saltzburg; also in mica-schiste at Mount Zabara in Upper Egypt, a locality whence the ancients are believed to have obtained their emeralds.

The Peruvian emerald, according to the analyses of Klaproth and Vauquelin, contains,

Silica	68·50	64·50
Alumina	15·75	16·00
Glucina	12·50	13·00
Oxide of iron	1·00	0·00
Oxide of chrome	0·30	3·25
Lime	0·25	1·60

Its specific gravity ranges between 2·6 and 2·8, and its hardness between 7·5 and 8·0 of the scale of Mohs; that is, it scratches quartz, and is very little inferior to topaz in hardness. It possesses a vitreous lustre more or less

Emeritus || Emerson.

shining, and a conchoidal uneven fracture. By friction it becomes electric; and before the blowpipe with borax it fuses into a transparent colourless glass. But it is as a gem, inferior only to the diamond and the ruby, that this mineral is so highly prized and esteemed. Its colour, which is perfectly distinct from that of any other gem, is very rich, and presents by daylight the most pleasing hue. Consequently this gem, when of considerable surface and free from flaws and impurities, has always been very highly prized, and, as Pliny observes (xxxvii.), in his time commanded immense sums. Haüy describes one in the tiara of the sovereign pontiff when in Paris in 1804, consisting of a cylinder about two inches long by two and a quarter broad, which is supposed to have been brought from Africa, as it bears the name of Julius II., who flourished anterior to the conquest of Peru. The most magnificent cut emerald in this country is that in the possession of Mr Hope of London. It weighs six ounces, is perfect in colour and transparency, and cost L.500. It is believed to be from Coimbetoor.

Emeralds are cut and polished with facility. The usual form given them is that of a square table with the edges replaced, the lower surface being cut into facets parallel to their sides. When fine they are always set without a foil; and, as their brilliancy is somewhat impaired by candle-light, they are generally surrounded with small diamonds or pearls, which enhance their lustre and effect. This gem has been very successfully imitated by the French manufacturers of paste stones, the colouring matter used being the oxide of chrome.

EMERITUS, a Latin word signifying one who has completed his term of service. It was the name given by the Romans to a soldier or other public functionary who was exempted from further duty, and received a retiring allowance.

EMERSION, in *Physics*, the rising of any solid above the surface of a fluid specifically heavier than itself in which it has been forcibly immerged.

EMERSION, in *Astronomy*, the gradual reappearance of the sun, moon, or other celestial body, after it has been eclipsed. It also denotes the reappearance of a star which has been hid in the effulgence of the sun's light.

EMERSON, WILLIAM, an eminent but eccentric mathematician, was born May 14, 1701, at Hurworth, near Darlington, where his father Dudley Emerson taught a school. From him young Emerson received a thorough mathematical education, and the bequest of a good mathematical library. In the earlier part of his life he followed his father's profession, but with little success; and having received a moderate competence from his parents, he soon after devoted himself entirely to studious retirement. Towards the close of 1781, he relinquished his studies and disposed of his library. His death took place soon after, May 20, 1782, at his native village, and in the eighty-first year of his age.

Emerson in person was rather short, but strong and well made, with an open countenance and ruddy complexion. In dress, manners, and appearance, he was eccentric and indeed clownish; but with all his eccentricities he possessed an uncompromising independence of character, and intellectual energy of a very high order. He invariably shut himself up in London during the publication of his works, and carefully revised them sheet by sheet himself, so that they are singularly free from errata. In mechanics, he never advanced a proposition which he had not previously tested in practice, nor published an invention without first proving its effects by a model. Emerson was married, but had no family. His wife employed her leisure in spinning on a curious wheel, of which an accurate drawing is given in his Mechanics; and his favourite recreation was fishing. He was skilled in the science of music, the theory of sounds, and the ancient and modern scales; but he never attained any excellence as a performer.

The following is a list of Emerson's works:—*The Doctrine of Fluxions*. 1748, 8vo; *The Projection of the Sphere, orthographic, stereographic, and gnomical*, 1749, 8vo; *The Elements of Trigonometry*, 1749, 8vo; *The Principles of Mechanics*, 1754, 8vo; *A Treatise of Navigation*, 1755, 12mo; *A Treatise of Algebra*, in two books, 1765, 8vo; *The Arithmetic of Infinites, and the Differential Method, illustrated by Examples*, 1767, 8vo; *Mechanics, or the Doctrine of Motion*, 1769, 8vo; *The Elements of Optics, in four books*, 1768, 8vo; *A System of Astronomy*, 1769, 8vo; *The Laws of Centripetal and Centrifugal Force*, 1769, 8vo; *The Mathematical Principles of Geography*, 1770, 8vo; *Tracts*, 1770, 8vo; *Cyclomathesis, or an easy Introduction to the several branches of the Mathematics*, 1770, in 10 vols. 8vo; *A short Comment on Sir Isaac Newton's Principia*; to which is added, *A Defence of Sir Isaac against the objections that have been made to several parts of his works*, 1770, 8vo; *A Miscellaneous Treatise, containing several Mathematical Subjects*, 1776, 8vo.

Emery || Emigration.

EMERY, a mineral substance long regarded as an ore of iron, but which appears to be a mixture of corundum and oxide of iron. Emery, reduced to a fine powder by grinding and elutriation, is very extensively used for polishing metals, glass, marble, and other hard bodies. It is imported into this country chiefly from the Isle of Naxos, where it exists in great quantities; and it also occurs in Germany, Italy, Spain, and in some other parts of the world. It is found in beds in strata of mica slate, and in colour is intermediate between grayish-black and bluish-gray. Specific gravity about 4·000. It varies considerably in quality. The constituents of good emery have been given as follows:—alumina, 80; silica, 3; iron, 4. The great hardness of emery constitutes its value as a material for polishing. Ground emery is used in various ways; as, for instance, applied with glue to paper, cloth, or wood, to be used in rubbing; or formed into paste as an artificial stone for grinding-wheels, &c.

EMETIC (ἐμέω, *to vomit*), a medicine that excites vomiting by a specific action on the stomach, independently of its taste or odour. The emetics most in use are ipecacuanha, the tartrate of antimony and potash (tartar emetic), sulphate of zinc, and sulphate of copper.

EMIGRATION is the act of leaving the country or place in which one has previously resided, in the view of residing in some other country or place. Persons so leaving the place of their residence are called emigrants; and latterly the term immigrants has been employed to designate persons arriving from a distance in some place or country with the intention of settling in it. Persons leaving a country for a while, to which they intend to return, are not reckoned emigrants. This term is appropriated to those who leave their present habitations to establish themselves permanently elsewhere. Definition

The motives which lead to emigration are various in the extreme; but, whatever its immediate cause may be, all emigrants expect either to avoid some considerable evil, or to improve or amend their situation. The natural multiplication of man and of the animals which he domesticates, and the tendency of both to increase beyond such means of subsistence as may be easily made available for their support, have been in all ages the great cause of emigrations. When the flocks and herds of the occupiers of particular districts began to be so numerous that pasture became deficient, it was an obvious resource, in the event of any unoccupied lands being in their vicinity, for a portion of the tribe to emigrate to them. The Book of Genesis affords a striking illustration of what is now stated. The herds of Abraham and Lot, it is there stated, had so greatly increased, that, there not being room for them both, contests took place between their servants. Whereupon Abraham said to Lot, "Is not the whole land before thee? Separate thyself, I pray thee, from me. If thou wilt take the left hand, then I will go to the right; or if thou depart to the right hand, then I will go to the left. Then Lot chose him all the plain of Jordan, and Lot journeyed east; and they separated themselves the one from the other." (Chap. xiii. v. 8–11.) And what happens to herdsmen hap- Motives which lead to emigration.

Emigration.

pens to agriculturists. It would be easy, indeed, to show, by entering into historical details, that this was in fact the way in which population was extended over all countries. But the thing is so very evident that this would be quite unnecessary—a mere accumulation of proof in a case where none is required.

Emigrations from Greece and Rome.

Many of the emigrants from the Greek states of antiquity consisted of citizens forced by the violence of contending factions to seek new settlements in other countries. But Greece also sent forth emigrants, impelled by the difficulty of maintaining themselves at home, or allured by the glowing descriptions of the comparative abundance they would enjoy in distant lands. Both these classes of emigrants established themselves, for the most part, either in countries with a scanty population, or whose inhabitants were in a decidedly lower state of civilization. And the greater refinement and ingenuity of the Greeks, and their industrious habits, enabled them to make a rapid progress, so that several of these colonies became, in no very lengthened period, populous and powerful states.

But few voluntary emigrants ever left Rome. The colonies which she sent forth were intended to bridle subjugated provinces, and should be regarded rather as the outposts of an immense army, the headquarters of which were at Rome, than as establishments of individuals who had bid adieu to their mother country, and who intended to maintain themselves in their new residence by their own industry.

Emigrations of the northern nations.

But in their wish to amend their condition, emigrants have not always been contented to establish themselves in unoccupied or thinly-peopled countries. Sometimes, as in the case of the irruption of the northern nations into the Roman empire, they have attacked countries that were densely peopled; and, having subdued the inhabitants, have seized upon the whole, or upon a greater or less proportion of their lands.

Pastoral nations, inasmuch as they can carry with them the flocks and herds from which they derive their subsistence, may emigrate in very large bodies; and previously to the invention of gunpowder, and other improvements in warfare, were very dangerous neighbours. The danger was further increased, or rather was perpetually kept up, by the fact that the emigration of one tribe or nation, by making more room for those that remained behind, gave a corresponding stimulus to population, so that the vacuum being soon filled up, the motive to fresh emigration became as great as ever. On this principle we are able to account satisfactorily for the successive swarms of barbarians that, issuing from the countries in the north of Europe, first attacked and ultimately overthrew the colossal fabric of Roman power. It admits of demonstration that these countries were then not nearly so populous as at present, that they had not more, perhaps, than a fifth or a sixth part of the inhabitants by which they are now occupied. But as they depended principally on pasturage, their numbers were often in excess compared with their means of support. And the pressure of want, that is, the necessity of finding additional room for their flocks and herds on the one hand, and, on the other, the prospect of vast wealth and riches of which they might hope to possess themselves, precipitated them into those expeditions in which, though often defeated, they were in the end successful. The lines of Gray, in reference to these irruptions, are as true as they are beautiful:

> The prostrate South to the destroyer yields
> Her boasted titles, and her golden fields:
> With grim delight the brood of winter view
> A brighter day, and heav'ns of azure hue;
> Scent the new fragrance of the breathing rose,
> And quaff the pendent vintage as it grows.

Thanks, however, to the progress of science and of arts, the civilized world is now secure against being again over run by barbarians. Those who overcome the armies, the fleets, and other means of defence of refined and polished nations, must themselves be to a considerable extent refined and polished. The brute force of mere barbarism can no longer contend with the tremendous energies which civilised nations can press into their service. If the sun of Europe is destined to be again obscured, it will not be by a fresh irruption of barbarians.

Emigrations to America and Australia.

In modern times America, and, more recently, Australia, have formed the favourite outlets for the emigrants from the Old World. When first discovered, these vast continents were wholly or almost wholly occupied by the scanty population of hunters, hardly more advanced than the wild animals which they made their prey. Europeans consequently had very little difficulty in subjugating and occupying the most extensive territories on the other side of the Atlantic and in the Southern Ocean, while their propitious climate and extraordinary fertility (of America at least) held out every encouragement to draw to them not only the poor and needy, but also the aspiring, the industrious, the discontented, and the rejected population of this and other old settled countries. To these America has truly been a "city of refuge." The hosts of paupers and outcasts that have fled or been driven to her hospitable shores have become citizens of free and independent communities, and have mostly attained to a state of comfort or it may be of independence. And the benefits of this emigration have not only been, but they continue to be, of a gigantic description. Besides the gain to humanity by the establishment of arts, science, and religion in the vast wildernesses of America and Australia, and the advantageous asylum they afford to all who resort to them, the endless variety and abundance of their animal, vegetable, and mineral products, supply the means of carrying on a commerce which is becoming every day more and more important, and which has already done more than anything else to stimulate the inventive and productive energies of the English and other nations of Europe.

And it is satisfactory to know, that notwithstanding the rapid progress of population in America, a long series of years will have to elapse before the temperate portions of that great continent will have accumulated anything like an average number of inhabitants. Owing to the general inferiority of its soil, Australia is not so well fitted to support a dense population as the extra-tropical regions of America. But what with its vast size, its prodigious mineral wealth, and other resources, it is not easy to anticipate to what a flourishing state it may arrive, or how long it may be a favourite resort of industrious emigrants.

Capacity of Asia Minor and the countries round the Black Sea to receive emigrants.

We are not, however, of the number of those who suppose that the field for emigration is to be restricted in all time to come to the temperate regions of America and to Australia. We believe that the events which are now in progress, whatever may be their results in other respects, will most probably assist in opening the extensive countries in south-eastern Europe and western Asia to the enterprise of Europeans. It is not possible to imagine that the great peninsula of Asia Minor, once the favoured seat of arts and industry, and of many flourishing and powerful states, should be destined to crouch indefinitely under the loathsome despotism which has so long weighed down and extinguished all its energies; and if it and the countries on the west and north shores of the Black Sea were once opened to settlers from the more civilized European States, their great extent, genial climate, and superior soil, would make them be eagerly resorted to by emigrants. At all events, it must be sufficiently obvious to any one who takes up a map of the world, that many generations may be expected to pass away before parties desirous of emigrating from the older European states will have much difficulty in finding localities in which they may advantageously establish themselves.

Emigration.

Impolicy of restrictions on emigration.

Hitherto most emigrations that have taken place have consisted of individuals who have emigrated at their own risk and expense. Sometimes, indeed, it has been attempted to hinder certain parties, such as skilled labourers, from emigrating, from an apprehension that they might, by instructing foreigners in their peculiar arts, enable them to become successful competitors in those arts with the countries which the emigrants had left. But such restrictions are at once oppressive and inefficient: oppressive because they hinder individuals from attempting to improve their condition by emigrating, and inefficient because the arts which they practise may be learned in a great many ways—by written descriptions, by foreigners sending emissaries to the countries in which they are practised, by their smuggling away a few individuals, and so forth. And we are glad to have to state that the justice of this reasoning is now generally admitted; and that, for some years past, all classes of artificers have had full liberty to leave this country.

Emigration may sometimes be advantageously assisted by government, &c.

But besides giving free leave to individuals to emigrate, there are many occasions in which it may he highly expedient for government and public bodies to come forward to assist them in leaving the country. Wherever there is a surplus population, that is, wherever the population is not wholly employed, or where, though employed, wages are so low as not to afford work-people a sufficient supply of necessaries and conveniences, emigration may be advantageously resorted to. The sum required to maintain an able-bodied labourer for twelve months or thereby in a workhouse would suffice to carry him to Upper Canada, or to some other part of America, where he would find immediate employment, and from being a pauper, would forthwith become independent. It is not easy, indeed, to see how the money of parishes could be more profitably laid out than in enabling such parties to emigrate. By doing so they relieve themselves at a trifling cost of a permanent burden; and while they greatly improve the condition of the emigrants, they also improve the condition of the labourers who are left at home, and raise up customers for our manufactures in foreign and distant countries.

Emigration from Ireland.

The late extraordinary emigration from Ireland (1846–1854) has done more perhaps to improve its condition than anything else that could have happened. In consequence of the diminution that has been effected in the population, employment is more easily obtained, and the rate of wages has increased; a considerable progress has been made in many parts of the country in the consolidation of small patches of land into something like farms of a reasonable size, and susceptible of a better system of cultivation; the towns and workhouses have been, in part at least, relieved of their pauper population; and agitation, crime, and outrage, are less prevalent. Nor is there any reason to fear, that either in Ireland or anywhere else, emigration will be, or indeed can be, carried to excess. The rise of wages and the brisker demand for labour, which it invariably occasions, are insuperable obstacles in the way of such a result. The danger, indeed, is all on the other side—that emigration will either stop or decline too much and too soon. It may yet be carried much farther with infinite advantage to Ireland. From the want of coal, Ireland is ill-fitted for manufacturing industry; and from the nature of the soil and the humidity of the climate, it is much better suited to pasturage than to tillage. And such being the case, the population is still (1854) so much in excess, that an emigration by which it would be farther reduced by one or two millions, would contribute most materially to its well-being.

Emigration cannot be carried to excess.

Emigration from the Highlands.

The emigrations from certain parts of the Scottish Highlands, in regard to which so loud a clamour was raised, have been highly advantageous to all parties directly or indirectly connected with them; to the emigrants who were carried from narrow, barren, and over-peopled districts, to countries of boundless extent, rich, and under-peopled; to the proprietors who were enabled to turn their estates to the best account; and to the public who are always interested in having lands occupied in the most beneficial manner. Unluckily the emigration has stopped far short of the point to which it ought to be carried. Many estates, both in the mainland and in the islands, continue to be overstocked with a half-employed, beggarly population.

Emigration.

Advantage of sending out female emigrants.

Owing to causes which are too obvious to need being pointed out, the greater number of emigrants, especially of those who go to new settlements, consist of males; and the want of a proper proportion of females is often productive of the worst consequences. Inasmuch, too, as the female portion of the population in old settled countries is generally that which is most in excess, it is plain that every facility and encouragement should be given to the emigration of women. Nothing, therefore, can be more consistent with sound policy than the efforts which have recently been made by government, and by private individuals, to send out well-conducted females to Australia; and it is to be hoped that they will not relax in their benevolent labours till the wide disproportion which now (1854) exists between the sexes in that continent be materially reduced.

Emigration from the United Kingdom, &c.

The application of steam to the propulsion of vessels and the other improvements that have been made in the art of navigation, have greatly diminished the cost, risk, and time spent in distant voyages, and have given a proportional extension to emigration. Notwithstanding their great distance, the emigration from Europe to America and Australia, but especially the former, has latterly attained to a magnitude which, previously to the employment of steam in navigation, would not have been conceived possible. For a lengthened period the United Kingdom has furnished the largest supply of transatlantic emigrants; but of late years the emigration from Germany has become very extensive, and promises at no distant period to equal, if it do not surpass, that which is carried on from this country. The vast majority of the German emigrants are destined for the United States, where (in Pennsylvania principally) they occupy extensive districts, and have established themselves in great numbers. The States have also become, since 1835, the principal resort of the emigrants from the United Kingdom, more particularly of those from Ireland; though large numbers of the English and Scotch emigrants, with a smaller number of Irish, continue to resort in preference to Canada. Since the discovery of the gold-fields of Australia, great numbers of emigrants have gone to that continent. But its much greater distance, and the consequent length and cost of the voyage, make it difficult for the poorer classes to find, without assistance, their way to this new El Dorado. And we may add, that to the natural difficulties in the way of emigration to Australia have been superadded those which arise from an extravagant *minimum* price of 20s. an acre having been set on all waste land in that continent, even though it should require three, four, or five acres to depasture a single sheep. But it is not to be supposed that this mischievous or rather insane regulation will be permitted much longer to disgrace our colonial legislation. It is abundantly certain, that its repeal will do more than anything else to promote the emigration to, and the settlement of, our great south-eastern colonies.

Next to the United Kingdom and Germany, China furnishes the greater number of over-sea emigrants. A Chinese population has long been settled in large numbers in many parts of the Eastern Archipelago, where they are distinguished by their industry and good order; and recently many thousands of them have found their way to California and Australia. We beg to subjoin an account of the number of emigrants from the United Kingdom in each year from 1815 to 1853, both inclusive, specifying the countries for which they sailed, and the numbers that sailed for each.

Years.	North American Colonies.	United States.	Australian Colonies and New Zealand.	All other Places.	Total.
1815	680	1,209	...	192	2,081
1816	3,370	9,022	...	118	12,510
1817	9,797	10,280	...	557	20,634
1818	15,136	12,429	...	222	27,787
1819	23,534	10,674	...	579	34,787
1820	17,921	6,745	..	1,063	25,729
1821	12,955	4,958	...	384	18,297
1822	16,013	4,137	...	279	20,429
1823	11,355	5,032	...	163	16,550
1824	8,774	5,152	...	99	14,025
1825	8,741	5,551	485	114	14,891
1826	12,818	7,063	903	116	20,900
1827	12,648	14,526	715	114	28,003
1828	12,084	12,817	1,056	135	26,092
1829	13,307	15,678	2,016	197	31,198
1830	30,574	24,887	1,242	204	56,907
1831	58,067	23,418	1,561	114	83,160
1832	66,339	32,872	3,733	196	103,140
1833	28,808	29,109	4,093	517	62,527
1834	40,060	33,074	2,800	288	76,222
1835	15,573	26,720	1,860	325	44,478
1836	34,226	37,774	3,124	293	75,417
1837	29,884	36,770	5,054	326	72,034
1838	4,577	14,332	14,021	292	33,222
1839	12,658	33,536	15,786	227	62,207
1840	32,293	40,642	15,850	1,958	90,743
1841	38,164	45,017	32,625	2,786	118,592
1842	54,123	63,852	8,534	1,835	128,344

Annual emigration from the United Kingdom—
From 1815 to 1853.................................. 97,269
For the five years ending 1853.................. 323,002

(J. R. M.)

EMINENCE, literally elevation or height; but usually a rising ground, or a hill of moderate elevation above the adjacent country, &c.

Eminence, as a title of honour, was first given to cardinals by a papal decree bearing date Jan. 10, 1630; previous to which time they had been addressed as *illustrissimi* and *reverendissimi.* The title of Eminence has been applied to various dignitaries at different times; as to the grand master of Malta, to the kings of France, the emperor, &c.

EMIR (*Arabic*), a title of dignity among the Turks. It signifies lord or chief, and was first given to the khalifs; but when they assumed the title of Sultan the title of Emir was given to their children, as that of Cæsar among the Romans. The title of Emir is now given, by prescriptive usage, to all who are considered to be descended from Mohammed by his daughter Fatima, and who consequently wear the green turban instead of the white. As prefixed to another word indicative of a particular command or office, it is a common title of dignity, and is borne by viziers, pachas, &c.

EMMANUEL, or Immanuel, a Hebrew word which signifies "God with us." It is applied to our Saviour as God-man, prophetically by Isaiah (vii. 14, viii. 8), and historically by Matthew (i. 23).

EMMERICH, a fortified town of Rhenish Prussia, government of Dusseldorf, situated on the right bank of the Rhine, 5 miles N.E. of Clèves. Pop. (1849) 6647. It has several churches, a gymnasium, Roman Catholic seminary; and manufactures of woollen and linen goods, leather, and soap. Emmerich was formerly a member of the Hanseatic League.

EMMIUS, Abbo (1547–1625), a celebrated historian and geographer, was born at Gretha in East Friesland. He was chosen rector of the college of Norden in 1579; but was ejected in 1587 for refusing to subscribe the confession of Augsburg. He was subsequently rector of the colleges of Leer and Gröningen, and ultimately professor in the university of the latter city. His principal works are—*Opus Chronologicum,* Grönin., 1619, fol.; *Vetus Græcia illustrata,* Leyd., 1626, 8vo; *Rerum Frisicarum Historia,* Leyd., 1616, fol.; *Historia Temporis nostri,* Grönin., 1732, 4to.

EMPALEMENT (Lat. *in,* and *palus,* a stake), a fencing or inclosing with stakes; a stockade. The word is particularly applied to a barbarous kind of punishment by thrusting a stake up the fundament, and thus leaving the victim to perish. Instances are on record of persons who lingered under this torture for several days. Empalement was much practised in ancient times at Rome; and even within a very recent period among the Turks and other barbarous nations.

EMPEDOCLES, a celebrated philosopher of Agrigentum in Sicily, who flourished about the middle of the fifth century B.C. Of his history little is known. He joined in the revolution by which Thrasydæus was expelled; and amongst his countrymen he enjoyed a reputation not only for statesmanship, but for supernatural ability to control the adverse powers of nature. The general story in regard to his death is that he threw himself into the crater of Mount Ætna, in order that no trace of his earthly existence might remain, and that he might seem to have been translated into heaven. The origin of this marvellous account, however, may be found in the too personal interpretation of his haughty pretensions as a philosopher, and especially of the opening lines of his *Katharmoi;* in which, in his own name, he treats of the divinity of the human soul. According to Aristotle, however, Empedocles died peacefully at the age of sixty. It is not easy to determine his relation to the great philosophical schools of antiquity; and in the allusions which he makes to a great master, it is difficult to say whether the reference is made to Pythagoras, Parmenides, or perhaps Anaxagoras. His philosophical scheme, although in the doctrine of transmigration of souls bearing some affinity to the Pythagorean system, and in the application of a mechanical physiology being closely related to the philosophy of Anaxagoras, belongs most properly to the Eclectic school. The whole phenomena of nature were by him resolved into the combinations of four primal elements—fire, air, water, and earth—by the attractive and repulsive forces of love and hate. Neither of these forces are to be regarded as external to the matter on which they act; love or Deity residing in the original chaotic mass of things, and hate or strife in the elements individually, among which fire holds the chief place as the great centre of intellectual and sentient life. The present normal order of things arose out of chaos by successive stages of combination, as the two great principles passed from inertness to activity; and as the elements become exhausted by a ceaseless change, they gradually yield to the blending influence of love, and withdraw into the inertness of the chaotic sphere. Empedocles seems also to have recognised a third force, that of necessity, based on the unconditional decree of the Deity. His theory of cognition is in strict accordance with his philosophical scheme in regard to the construction of the universe. Man, as composed of the four elements, and subjected to the influence of the two antagonistic forces, can only rise to a comprehensive knowledge of the universal whole through the paramount influence of love. Accordingly, what is apprehended by the senses must be carefully distinguished from the results of the pure intellect alone, the pure unity

of truth residing only in the pure unity of love or Deity. The fragments of Empedocles have been collected and published by F. W. Sturz, Leipzig, 1805.

EMPEROR (*imperator*), among the ancient Romans, signified the general of an army, who, for some extraordinary success, had been complimented with this appellation. Thus Augustus, having obtained no less than twenty famous victories, was as often saluted with the title; and Titus was thus styled by his army after the reduction of Jerusalem. Subsequently it came to denominate an absolute monarch or supreme commander of an empire. In this sense Julius Cæsar was called *imperator*. The same title descended with the dignity to Octavianus Augustus, Tiberius, and Caligula; and afterwards it became elective. In strictness the title *emperor* does not, and cannot, add anything to the rights of sovereignty. In the East the title of emperor is more frequent than in Europe. Thus, the sovereign princes of China, Japan, Mogul, &c., are all emperors. In Europe, the first who bore the title was Charlemagne, who assumed it on his coronation at Rome by Pope Leo III.

EMPHYSEMA, a distension of the body or its members from an accumulation of air in the cellular or adipose membrane, by which the part is rendered tense and elastic, so that it crepitates when pressed.

EMPIRE (*imperium*), in *Political Geography*, the territory, region, or countries under the jurisdiction or government of an emperor. We read in ancient history of four great monarchies or empires; namely, that of the Babylonians, Chaldeans, and Assyrians; that of the Medes and Persians; that of the Greeks; and that of the Romans. The first subsisted from the time of Nimrod, who founded it in the year of the world 1800, according to the computation of Usher, till that of Sardanapalus, their last king, in 3257; and consequently lasted above 1450 years. The empire of the Medes commenced under Arbaces, in the year of the world 3257, was united to that of the Babylonians and Persians under Cyrus in 3468, and closed with the death of Darius Codomannus in 3674. The Grecian empire lasted only during the reign of Alexander the Great, beginning in the year of the world 3674, and terminating with the death of this conqueror in 3681, his conquests having been divided amongst his captains. The Roman empire commenced with Julius Cæsar, when he was made perpetual dictator, in the year of the city 708, and of the world 3956, forty-eight years before Christ. The seat of the empire was removed to Byzantium by Constantine, in the year of our Lord 334; and the East and West were then united under the title of the Roman empire, till the Romans proclaimed Charlemagne emperor in the year 800. From this epoch the East and West formed two separate empires. That of the East, governed by Greek emperors, commenced in the year 302; and, being gradually weakened, terminated under Constantine Palæologus in 1453. The Western empire was afterwards known by the appellation of the empire, or German empire. Antiquaries distinguish between the medals of the Upper and Lower Empire. The curious only value those of the Upper Empire, which commenced with J. Cæsar, or Augustus, and ended in the year of Christ 476. The Lower Empire comprehended near 1200 years, reckoning downwards till the destruction of Constantinople in 1453. Two ages or periods of the Lower Empire are usually distinguished; the first beginning where the Upper ends, namely, with Aurelian, and terminating with Anastasius, including 200 years; and the second beginning with Anastasius, and ending with the Palæologi, which includes 1000 years.

The Empire, used absolutely and without any addition, signifies the empire of Germany, which is also called in juridical acts and laws the Holy Roman Empire. It had its beginning at the commencement of the ninth century, when Charlemagne was created first emperor by Pope Leo III., who put the crown on his head in St Peter's church on Christmas day in the year 800.

EMPIRIC (ἐμπειρία, *experience*), one whose knowledge is founded on experience. The name of *Emperici* was given to an ancient sect of Greek physicians who contended that experience alone was needful in the healing art. Philinus of Cos is the reputed author of this system, which was greatly extended and improved by Serapion of Alexandria. From the pretensions and ignorance exhibited by many of this sect, the term empiric has become a common designation for one who enters on practice without a regular professional education; and, in general, for a quack, or pretender to medical skill.

EMPORIUM, in a general sense, signifies a city or place where extensive commercial transactions are carried on; but it is more particularly applied to the commercial centre of a country, or the place to which buyers and sellers from various countries resort.

EMPSON, WILLIAM, an able critic and scholar, professor of civil law at Haileybury College, was born in 1790. He was educated at Winchester, and afterwards at Trinity College, Cambridge. On the death of Napier he succeeded to the editorship of the *Edinburgh Review*, chiefly through the influence of Francis Jeffrey, whose only child he had previously married. He contributed to the *Review* upwards of sixty articles on various subjects. The best known is that on Stanley's *Life of Arnold*. Empson died at Haileybury, Dec. 10, 1852.

EMPYEMA, a collection of pus in the cavity of the thorax; a not infrequent result of pleurisy. The purulent matter is sometimes removed by making an opening for its discharge between the sixth and seventh ribs.

EMPYREUM, or EMPYREAN (ἐμπυρεύω, *I kindle*), a fanciful name given to the highest heaven, because of its supposed splendour, as being formed of the pure element of fire or light.

EMPYREUMA, in *Chemistry*, the offensive odour given out by burnt oils; as in the distillation of animal and vegetable substances.

EMS, a watering-place of Nassau, and 6 miles W.N.W. of the town of that name. It is pleasantly situated on the Lahn, and has several thermal springs. Pop. about 800.

EMS, the ancient *Amisus*, a river in the N.W. of Germany, rising in the Teutoburg forest, Westphalia, S.W. of Detmold. It flows first westward through the Prussian territory, and afterwards takes a northern direction through Hanover, to the Dollart, a gulf of the North Sea between Holland and Hanover. It has an entire course of about 160 miles, and is navigable for vessels of 80 or 100 tons as far as Passenburg. The principal tributaries are the Aa, the Haase, and the Leda, which fall into it from the right.

EMU, or EMEU. See ORNITHOLOGY.

ENALIOSAURIA (ἐνάλιος *living in the sea*, and σαύρος *a lizard*), in *Geology*, a name given to the entire group of extinct saurian animals which are characterized by broad paddle-shaped feet, like those of the whale or turtle, and a head and trunk resembling those of the crocodile.

ENAMEL (Fr. *émail*) a semi-transparent or opaque vitrified substance, of the nature of glass, but differing from it by possessing a greater degree of fusibility and opacity. The compound which serves as a basis to most kinds of enamel is formed by the fusion of a pure crystal glass or frit, ground up with a fine calx of lead and tin, in certain proportions; to which is usually added white salt of tartar. The different kinds of enamel are made by the addition of colouring substances, and melting or incorporating the whole by fusion.

For white enamel, Neri (*De Arte Vitriar.*) directs only manganese to be added to the matter which constitutes the basis; for azure, zaffer mixed with calx of brass; for green, calx of brass with scales of iron, or with crocus martis; for black, zaffer with manganese or with crocus martis, or manganese with tartar; for red, manganese, or calx of copper and crude tartar; for purple, manganese with calx of brass; for yellow, tartar and manganese; and for violet-coloured

enamel, manganese with thrice-calcined brass. In making these enamels great nicety is requisite. The general way of making the coloured enamel is this: Powder, sift, and grind all the colours very nicely, and first mix them with one another, and then with the common matter of enamels; next set them in pots in a furnace, and when they are well mixed and incorporated, cast them into water; when dry, set them in a furnace again to melt; and when melted, take a proof of the enamel. If too deep-coloured, add more of the common matter of enamels; and if too pale, add more of the colours.

ENAMELLING, the art of laying enamel upon metals, as gold, silver, copper, &c. Enamel ornaments for trinkets, in almost endless variety, may be produced by the aid of the blowpipe. The enamel is usually first drawn out into threads, or reduced to thin laminæ, to facilitate the process of fusion; and by the same means the enamel may be laid upon metals. Very elegant ornamental work may be thus produced. Enamelling also signifies to paint in enamel.

Painting in enamel is performed on plates of gold or of copper, but seldom on silver, as this metal is apt to occasion imperfections in the surface of the enamel. Copper is the metal most generally used for this purpose, enamelled with the white enamel, on which painting is executed with colours which are melted in the fire, where they take a brightness and lustre like that of glass. This kind of painting is particularly prized for its peculiar brightness and vivacity, which is permanent, the force of its colours not being liable to be effaced or sullied with time, as in other painting, and continuing always as fresh as when it came out of the workman's hands. This method of painting is almost entirely confined to miniature; larger works being liable to certain accidents in the operation. The most perfect kind of enamelling is practised on plates of gold, the other metals being less pure. Copper, for instance, sometimes scales with the application; and silver turns the yellow white. To obviate the cracking of the enamel, the plates are generally made a little round or oval and rather thin. The operation is usually commenced by laying on a couch of white enamel on both sides of the plate, which prevents the metal from swelling and blistering; and this first layer serves for the ground of all the other colours. The next step is to draw out exactly the subject to be painted with red vitriol, mixed with oil of spike, marking all parts of the design very lightly with a pencil. After this, the colours (very finely ground, and mixed with oil of spike somewhat thick) are to be laid on, attention being given to the mixtures and colours which agree to the different parts of the subject; for which purpose it is necessary to understand painting in miniature.

When the colours are all laid, the painting is to be gently dried over a slow fire to evaporate the oil, and the colours are afterwards melted to incorporate them with the enamel, making the plate red hot in a fire such as enamellers use. Afterwards, the painting may be retouched; and is then to be committed a second time to the fire, and so on till the work be completed.

ENCAUSTIC, and Encaustum, the same with enamelling and enamel.

Encaustic *Painting*, a method of painting among the ancients, in which wax was employed to give a gloss to the colours, and to preserve them from injury.

This ancient and lost art was in a manner revived by Count Caylus, who announced his method to the Academy of Painting and Belles-Lettres in the year 1753; though M. Bachelier, the author of a treatise *De l'Histoire et du Secret de la Peinture en Cire*, had produced a picture in wax in 1749; and was the first who communicated to the public the method of performing the operation of inustion, which is the principal characteristic of encaustic painting. The count kept his method a secret for some time, but exhibited at the Louvre, in 1754, a picture representing the head of Minerva, painted in wax, which excited much curiosity. In the interval of suspense several attempts were made to recover the ancient method of painting; such as that of melting wax and oil of turpentine together, and using this composition as a vehicle for the colours. But this method did not explain Pliny's meaning, as in this way of managing it the wax is not burnt. In another attempt, the wax was melted with strong lixivium of salt of tartar, and with this the colours were ground. When the picture was finished, it was gently heated, so as to melt the wax, and diffuse it through all the particles of the colours; and thus they were fixed to the ground, and secured from the access of air or moisture. But the method of Count Caylus was much more simple. The canvas or panel was waxed over by rubbing it simply with a piece of bees-wax; the panel or canvas being held before a fire, that the wax might gradually penetrate the body, and fill the interstices of the texture of the cloth, which when cool was painted upon; but as water-colours, or those which are mixed up with common water, will not adhere to the wax, the count directs that the canvas or panel thus prepared be first rubbed over with Spanish white. When the picture is dry, it is to be placed near a fire, when the wax melts and absorbs the colours.

Mr J. H. Muntz, in a treatise on this subject, proposed several improvements. If the painting be on cloth, he directs it to be prepared by rubbing one side several times over with a piece of virgin wax, till it be coated to a considerable thickness. In fine linen this is the only operation necessary previous to painting; but coarse cloth must be smoothed on the unwaxed side with a pumice-stone. The subject is then to be painted on the unwaxed side with colours prepared and tempered with water; and when the picture is finished, it is to be exposed to the fire, that the wax may melt and fix the colours. Crayons may be used in a similar manner.

ENCEINTE (Fr. from *cingere, to gird*), in *Fortification*, the interior wall or rampart which surrounds a place; sometimes composed of bastions or curtains, and sometimes only flanked by towers, which is called a *Roman wall*.

ENCHANTMENT. See Divination; Magic; Dæmon; Witchcraft.

ENCHASING, or Chasing, the art of embossing or making figures in low relief upon gold, silver, and other metals. It is practised only on hollow thin works, such as watch-cases, tankards, cups, &c. The design having been traced on the exterior surface of the metal, the work is hammered upon steel blocks or puncheons introduced within; and thus the workman proceeds to indent the metal by the successive application of the block and hammer to the several parts of the design; after which the work is cleared with small chisels and gravers. In this simple manner a skilful artist is able to represent foliages, figures, &c. with admirable precision.

ENCHORIAL Characters. See Demotic.

ENCYCLOPÆDIA (ἐν *in*, κύκλος *a circle*, παιδεία *instruction*), a term nearly synonymous with Cyclopædia, but adopted in preference to it in denominating the present work, as being etymologically more definite and complete. For, as it has been justly remarked—*Cyclopædia* may denote "the instruction *of* a circle," as *Cyropædia* is "the instruction of Cyrus;" whereas in *Encyclopædia*, the preposition determines the meaning to be "instruction *in* a circle." Vossius, in his book *De Vitiis Sermonis*, observes—"that *Cyclopædia* is used by some authors, but *Encyclopædia* by the best." Some account of the history and merits of the different Encyclopædias which have appeared will be found in the General Preface to this work.

ENDEMIC, or Endemial (ἐν *amongst*, δῆμος *the people*), peculiar to a people or nation. *Endemic diseases* are those to which the inhabitants of a particular district are peculiarly subject, and which, for that reason, are attributed

to such causes as bad air or water, or the manner of living. Thus agues or intermittent fevers are endemic in low marshy districts; the *goitre* in the Alps; *plica trichosis* or *Polonica* in Poland.

Epidemic, again, is applied to those diseases which, independently of such causes, seize many persons at or about the same season, in the same country or district. Thus, influenza, measles, scarlet-fever, &c., are sometimes epidemic. It may be observed—that according to the medical notion of the term, it is essential that the prevalence of the disease be temporary.

ENDOGENS, one of the primary classes of plants, which includes those of which the stems grow by successive additions to the interior; as in the palms, grasses, and liliaceous plants.

ENDOR, a town of Galilee; chiefly memorable as the abode of the sorceress whom Saul consulted on the eve of the battle in which he perished (1 Sam. xxviii.) In the time of Eusebius and Jerome it still existed as a large village, 4 miles S. of Mount Tabor; and at this distance, on the northern slope of the lower ridge of Hermon, there is still a village of this name.

ENDYMION, the poetic impersonation of perennial sleep. By the ancient mythologists he is variously represented as the successor of Aëthlius on the throne of Elis, or as a shepherd or huntsman perpetually asleep in the caves of Mount Latmus in Caria, and lulled by the kisses of the fair Selene, the goddess of the moon. According to the former and more prosaic tradition he was the son of Aëthlius and Calyce; and on his wandering to Caria, was succeeded by his son Epeius, who won the crown of Elis by a successful contest in the race-course at Olympia. He was thrown into an eternal sleep either as a punishment or as a gift from Jupiter; or according to others, under the spell of the enamoured Selene. On this legend Keats has founded his exquisite poetical romance of *Endymion*.

ENFIELD, William, LL.D., a Dissenting divine of considerable eminence, was born at Sudbury in 1741. He received his education at the Dissenting academy at Daventry, then conducted by Dr Ashworth, and was chosen minister of the congregation of Benn's Garden, Liverpool, in 1763. During his residence in Liverpool he published two volumes of sermons, as well as a collection of hymns and family prayers, which met with a very favourable reception. In 1770 he was appointed tutor and lecturer on the belles-lettres at Warrington academy, an office which he held till the dissolution of the academy in 1783. After the interval of a few years spent in private tuition, he was chosen pastor of the Dissenting congregation of Octagon Street, where he remained till his death, which took place Nov. 3, 1797, in the 57th year of his age. During his residence in Liverpool he married the daughter of a respectable draper in that city, and to her he was much indebted for the tranquillity and happiness of his life. Of the works of Dr Enfield a considerable number are mere compilations in which no higher quality is displayed than the taste which dictated the selection. To this class belong the *Preacher's Directory*, the *English Preacher*, the *Speaker*, and others. Among his original works, however, and especially those published or written at the close of his life, there are some that display considerable powers of thought and great elegance of expression. His posthumous sermons on the principal characters of the Old and New Testaments not only evince the author's ability as a commentator, but show profound insight into the ethics of history. At the recommendation of Dr Bagot, bishop of Norwich, he published an abridgment of Brucker's *History of Philosophy*, in 2 vols. 4to. He also wrote a work entitled the *Institutes of Natural Philosophy, theoretical and experimental*, 4to, 1783; besides a variety of occasional pamphlets and sermons.

Enfield, a village of the hundred of Edmonton, in the county of Middlesex, 10 miles from London. There are the remains of an ancient royal palace, in which Edward VI. kept his court, and where Elizabeth rested on her way to London in order to assume the crown. Near to it was Enfield chase, disforested in 1779, divided between various parishes and the crown, and now occupied by several country seats of the more opulent traders of London. The parish is extensive. Pop. (1851) 9453.

ENFILADE, in the military art, is used of the situation of a trench or other place which may be scoured by shot along its whole length. *To enfilade*, signifies to scour or rake with shot through the whole length of such line.

ENGADINE, the largest valley of Switzerland, after the Vallais, is in the Canton of the Grisons, and extends from S.W. to N.E. between the Lepontian and Rhaetian Alps. It is 18 leagues in length, with an average breadth of half a league, and is traversed through its entire extent by the Inn. The valley is rich in pasture, and a great part of the mountains are covered with pine forests; the climate is cold, and snow is absent only from June to September.

ENGASTRIMYTHI, in Pagan theology, the Pythias or priestesses of Apollo who delivered oracles without any action of the mouth or lips. The ancient philosophers, and others, are divided upon the subject of the engastrimythi. Hippocrates mentions this peculiar manifestation as a disease; some have regarded it as a kind of divination; others attribute it to the agency of an evil spirit; and others again to art and mechanism. Scotus supposes that the engastrimythi were poets, who, when the priestesses could not speak, supplied the defect by explaining in verse what Apollo dictated in the cavity of the sacred tripod.

ENGHIEN, a town of Belgium, province of Hainault, 18 miles N.N.E. of Mons. Pop. (1851) 3785. It has a fine chateau with a park and garden, a gymnasium, and manufactures of linen and cotton stuffs.

Enghien, *Louis-Antoine*—Henri de Bourbon Condé, Duc d'Enghien, was born at Chantilly on the 2d of August 1772. He quitted France with the French princes in 1789, and travelled till 1792 in Belgium and Piedmont, where, the emigrants having formed several corps, the Duc d'Enghien served in the army of the Condé and greatly distinguished himself in numerous engagements. At the treaty of Lunéville the corps of Condé was disbanded, and he was forced to lay down his arms. He then retired to Ettenheim, an ancient residence of the Cardinal de Rohan, on the right bank of the Rhine, four leagues from Strasburg, in the electorate of Baden, accompanied by Mademoiselle de Rohan, with whom he had formed a connection in 1794, which was only terminated with his death in 1804. (For an account of his seizure and murder, see France.)

ENGINEER, properly signifies a person who is employed in devising or constructing engines or machines, and in directing their applications.

The *Military Engineer* is an officer whose business it is to delineate the plans and direct the formation of military works, and to regulate attacks and defences. The branches of knowledge which more particularly relate to his profession are treated under the heads Artillery, Fortification, Gunnery, and War.

The *Civil Engineer* is one who applies the principles of mechanical and physical philosophy to the construction of the machines and public works by which the arts and accommodations of civil life are rendered more efficient, extensive, and secure. The subjects which more immediately belong to his important calling are treated under the following heads; Bridge, Carpentry, Docks, Gas-Lights, Navigation, Navigation Inland, Railways, Roads, Lighthouses, Ship-Building, Tunnels, Water-works, &c.; and also under the heads Dynamics, Hydrodynamics, Machinery, Mensuration, Resistance of Fluids, Strength of Materials, &c.

ENGLAND,

History. 700.

THE southern division of the island of Great Britain. In treating of this grand division of the British empire, we shall divide the subject into three Parts; the first comprehending the History of England, the second the Statistics of that country, and the third some account of its Government and Laws.

History. 800.

PART I.

HISTORY.

THE history of England, till the period of the Saxon Conquest, has been fully treated of in the first chapter of the article BRITAIN. After that event the country relapsed into a state of obscure barbarism, nearly as great as that from which it had been rescued by the Romans. The provincial Britons had profited by their intercourse with that great people. From the latter they had learned many of the arts of civilized life, and during the period of their subjugation they had erected a considerable number of cities, towns, and villages; but these were subsequently levelled with the ground by barbarian invaders, and the natives were frequently involved in the same ruin with their habitations. We are informed by one historian that a mighty conflagration began on the western coast, and gradually extended itself over the whole island. To escape from the exterminating swords of the Saxons, the Britons sought refuge in their native fastnesses; and thus the spark of civilization which had been struck out amongst them, and which, in more auspicious circumstances, might have kindled into a generous flame, was totally extinguished.

About the year 700, the island of Great Britain was divided into no fewer than fifteen sovereignties. Of these, eight were Saxon; but the union of the two Northumbrian principalities reduced the number to seven; and from this circumstance, as well as from some vague alliance amongst these petty states, historians have designated the whole by the name of the Heptarchy. They ruled over a considerable portion of England, and whilst they waged a fierce and endless war with every other kingdom in the island, they also maintained amongst themselves a continual struggle for the superiority. It would appear that one state usually exercised an undefined power over all the others; and the prince who possessed this equivocal ascendency had the title of *Bretwalda*, or wielder of the Britons, bestowed upon him. The history of this period is not characterized by any event which would lead us to take an interest in the fluctuating fortunes of the various states. Our information relating to the earliest portion of the Saxon rule is also scanty; but what we do possess is not of such a nature as to awaken any feelings of regret that more minute particulars have not been transmitted to us. Details of the shedding of kindred blood, and acts of oppression, treachery, and cruelty, exercised towards the natives by the fierce invaders of their soil, are not calculated to interest human feelings. The re-introduction of Christianity, however, in some degree alleviated the darkness of the picture. The exact date of its first appearance in Britain is uncertain, but it had made some progress before the close of the second century. It disappeared however, with the other traces of civilization, when the Saxons commenced their devastations. It was in the year 596 that Gregory the Great sent over St Augustin, with forty other missionaries, to convert the Saxons; and their arrival in Kent marks a new era in its history, and probably in that of the country. At this period Kent was governed by Ethebert, an able and powerful monarch and the third who bore the title of Bretwalda. He received kindly the deputies of Rome, and became a convert to their doctrine; an example which his subjects were not slow in following. From this period the spread of the Christian faith over the island appears to have been rapid; for we find that in about a century after the arrival of St Augustin it was professed and believed throughout Anglo-Saxon Britain. That it conferred many temporal benefits upon the community, cannot be doubted. But, however its divine precepts may have influenced the conduct and ameliorated the lot of individuals, crimes upon a great scale continued to be perpetrated as formerly. It may have mitigated the horrors of war, but battle followed on battle with as uniform a succession, and native blood flowed as freely, as heretofore. The continual struggle amongst the Anglo-Saxon principalities for the supremacy was however fast coming to a crisis. It is evident that such a state of affairs could not continue for any length of time, and that it must necessarily end in the establishment of a regular hereditary magistracy in the island. This took place partially at the beginning of the eighth century, in the person of Egbert, king of Wessex, who was a lineal descendant, and the only surviving prince, of the house of Cerdic, the founder of that kingdom. The great talents which he early exhibited had given offence to Brihtric, king of Wessex, who, jealous of his popularity, projected his destruction. Egbert, however, eluded his vengeance, and fled for protection to Offa, king of Mercia, a monarch illustrious for the talents he displayed and the prosperity he enjoyed, but whose name is stained with perfidy and blood. Thither the vindictive Brihtric pursued the youthful fugitive, who was finally compelled to cross the channel and to seek shelter beneath the broad shield of the victorious Charlemagne. France, governed by that renowned sovereign, excelled all the states of the West in civilization and the arts of government, as well as those of war. Trained in such a school, therefore, and early disciplined by adversity, he was undergoing an admirable probation for wielding with judgment and moderation the perilous sceptre which was destined to be transferred into his hands. The death of Brihtric, who perished by the machinations of his queen, recalled the fugitive from his exile. In Wessex the claim of Egbert was at once acknowledged, while his accession to the throne of his celebrated ancestor, an event highly popular in itself, was ennobled by a victory, the omen of many a future triumph.

At this period the island, though nominally under a hexarchy, was rapidly verging to a triarchy, from several of the smaller states becoming gradually blended and identified with their more powerful neighbours. Wessex had been enlarged by the incorporation of Sussex; and various favourable circumstances conspired to concentrate in the hands of Egbert a well-organized power, which he was prepared to wield when summoned by any great emergency. For several years, however, after his accession to the throne, his sword remained in its sheath; and this pro- A. D. 800.

pitious period of tranquillity afforded him an opportunity of turning his undivided attention to the affairs of government. His administration was as mild as it appears to have been politic; circumstances which completed the attachment of his subjects, and consolidated his growing strength. It was upon the unfortunate Britons of the west that he first made trial of his military prowess. About the year 809 the struggle between him and the natives commenced. The latter made a strenuous but unavailing resistance; and Egbert carried the havoc of war and the flames of destruction from the east to the west. In a few years the greater part of modern Wales, as well as the people who occupied the northern shore of the estuary of the Severn, acknowledged his authority. The king of Mercia, whose strength had been augmented by the appropriation of the petty sovereignties of Kent, Essex, and East Anglia, was now the only rival for the supreme authority whom Egbert had to fear or to contend withal. Their power was nearly equally balanced, for what Wessex wanted in numerical force was compensated by discipline and skill. War had now become inevitable; neither would brook a superior, and only one Bretwalda could be acknowledged. The conflict began, therefore, and was speedily brought to a termination. In an obstinate and bloody battle the king of Mercia was totally defeated, and Egbert became lord of the ascendant. State after state was annexed to Wessex; Mercia was invaded and subdued; and in nineteen years after he had first drawn the sword, Egbert was acknowledged over the greater part of the island as the eighth Bretwalda.

The authority of Egbert, however, still continued doubtful; and the Anglo-Saxon power was as yet very far from being consolidated. The fortunes and immunities of those composing the several states were not dependent upon one common legislature; and in regard to the details of government, the whole principalities remained as distinct from each other as before. Wales still continued to annoy him; and it was not until he had marched an army to Snowden that North Wales quietly submitted to that of the Saxon Bretwalda. But new and more formidable enemies than any he had yet encountered had begun to threaten England, and trouble the tranquillity which it in some measure enjoyed. These were Scandinavians, recognised in France by the name of Normans, and in England by that of Danes. Familiarized, from their maritime situation, to the dangers of the ocean, this people, like the Saxons of old, spent the greater portion of their time upon its waves. A pernicious law of succession, which consigned the whole patrimony to the eldest son, drove the younger branches of families to seek their fortunes by means of their ships and their swords. It was only in this manner that they could acquire riches and renown; and such pursuits were peculiarly agreeable to a people who unhappily preferred the acquisitions of rapine to the fruits of laborious industry. It was the custom of these pirates to set sail for some distant province in squadrons, under the command of chieftains called *Vikingr*, or Sea-Kings. After pillaging the coast where they landed, they collected the spoil and returned to their own country, where they disencumbered themselves of their booty and prepared for fresh expeditions. Three descents upon England are recorded as having taken place in the eighth century, but these attempts produced no permanent alarm. Towards the termination of Egbert's reign, however, the numbers of the pirates greatly increased, whilst their visits were annually renewed; and for two centuries to come the country was destined to be a prey to these fierce and fearless invaders.

After making several successful inroads into various parts of England, in 835 they landed on the coast of Cornwall, where they succeeded in seducing the Britons from their allegiance. The king of Wessex met the united forces of the enemy at Hengstone Hill, and gained a bloody but decisive victory, which restored the glory of his arms. This was the last exploit of Egbert, who died the year following, after a reign as prosperous as it was long, and which, allowing something for the condition of society at the period, may also be termed glorious.

Ethelwolf succeeded his father on the throne of Wessex; but an unfortunate arrangement, by which the former king bequeathed all his dominions except Wessex to a younger son, greatly weakened the power of his successor, and lessened the influence of the Bretwalda. Ethelwolf had been a monk, and appears to have been better adapted for the cloister which he had left than the throne which he now ascended. The history of his reign presents little of interest or variety. It is merely an account of the atrocities of the Danes, who made repeated descents upon England, laying waste the country, plundering towns, and despoiling the rich monasteries, where treasure was supposed to have been accumulated. No defeat, however signal and decisive for the time, was capable of permanently expelling them from the island; and although routed and compelled to flee for shelter to their ships one year, they returned the next with persevering audacity. In the meanwhile Ethelwolf found leisure to perform a pilgrimage to Rome; and in passing through France on his journey homewards, he espoused Judith the daughter of Charles the Bald, king of the Franks. But he was not permitted to enjoy undisturbed domestic tranquillity. On his return to England he found his son Ethelbald at the head of a formidable conspiracy, which threatened him with deposition and exile. The two parties, however, came without bloodshed to terms of accommodation. It was agreed that Ethelwolf should possess the eastern states appertaining to Wessex, whilst the kingdom of Wessex proper, which belonged of right to the head of the family, should be enjoyed by Ethelbald, but, it would appear, with a nominal subjection to his father. Ethelwolf survived these arrangements only a few years, having died in 858.

After his demise Ethelbald continued to occupy the throne of Wessex; whilst Ethelbert, a younger brother, succeeded to the government which had been left vacant by the death of his father; but both these princes died in a few years, and left their thrones to their brother Ethelred, who assumed the sceptre at a most unpropitious period. Not only was the kingdom divided against itself, but the Danes, acting now in a well-organized confederacy, and terrible from their numbers as well as from the frequency of their inroads, threatened the total annihilation of the Saxon dynasty and the subjugation of the island. In the reign of Ethelred ancient chroniclers present us with little else than accounts of battles fought and towns sacked, prolonged by all the sickening minutiæ of rapine and bloodshed. The conflicts were numerous and sanguinary; and in one of these, which took place at Merton in the year 870, the king received a wound of which he soon afterwards died.

By the death of Ethelred the throne of Wessex devolved upon Alfred, the fifth and favourite son of Ethelwolf. As an account of this extraordinary individual has already been given under the head of Alfred, it is unnecessary to recapitulate the events of his life. He was succeeded by his son Edward, who ascended what may now almost be termed the throne of England, in the year 901. Alfred had been called to the crown in preference to the children of his elder brother, who were considered at the time as too young to be entrusted with the government. Their pretensions being also set aside at his death, Ethelwold, one of the rejected princes, attempted by violence to seize hold of the royal authority. He formed an alliance with

History. 924.

the Danes and other enemies of Edward; but in a battle with the men of Kent he met his fate, and the island was once more rescued from a destructive competition for the crown.

Previously to this event the Danes had contrived, by a union with some of the disaffected provinces, to obtain a kind of permanent footing in the country. They possessed the north of England from the Humber to the Tweed, and the eastern districts from the Ouse to the sea. Emboldened by their strength, they invaded Mercia, but were met by Edward, who obtained over them a decisive victory, which effectually restored his supremacy. The most remarkable individual after Edward was his sister Ethelfleda, upon whom the mantle of Alfred seems to have descended. She governed Mercia, and vigorously seconded her brother in fortifying the country against the common enemy. Upon her death in 920 the Anglo-Saxon monarchy received additional security from the final incorporation of Mercia with Wessex. After various successes over his northern and other enemies, Edward the elder expired at Farrington in Berkshire, in the year 924. This monarch would appear to greater advantage were he not viewed in such close proximity to Alfred the Great, the brilliancy of whose reign was calculated to eclipse that of his successor, had the latter been even a greater man than he actually was. Edward, however, was a great man, and every way worthy to wield the sceptre of his father, which he did with uncommon judgment and success.

He was succeeded by his son Athelstane, whom historians, on the faith of an old song, are in the habit of styling illegitimate; but a contemporary poetess has recognised his mother as the partner of Edward's throne, a circumstance which fairly balances the former authority. There is one argument in favour of his legitimacy, which, as far as we are aware, has been overlooked; it is the exceeding partiality evinced towards him by his grandfather Alfred. It seems improbable that an individual, whose moral rectitude and ardent piety were so conspicuous as those of Alfred, should have singled out as his especial favourite one whose birth was a public scandal; that he should also have invested him with the insignia of knighthood whilst yet a child, and looked upon him as the future hope of Britain, more especially as, supposing the youth to have been a natural son, the legitimate children of his father had a preferable right to the throne. Viewing the matter in this light, the truth of the hypothesis that Athelstane was the fruit of a union sanctioned by law and religion appears highly probable, even allowing that the distinction of natural from legitimate children was at that period somewhat faint. It does not appear to have been so in the mind of Alfred the Great.

Athelstane was thirty years of age when his father expired; and Mercia immediately, and Wessex shortly afterwards, recognised him as king. Opposition was, however, experienced in other quarters; but he ultimately succeeded in seating himself firmly upon the throne, and fully justified the early popularity he enjoyed with his grandfather. In the person of Athelstane the Anglo-Saxon sovereign became a character of dignity and consequence in Europe. His connections with the most respectable potentates on the Continent gave to his reign a political importance, and he is moreover entitled to be considered as the first monarch of England.

The sovereignty of the whole island appears to have been the object of Athelstane's ambition. In his military enterprises he was completely successful, and compelled the princes of the Scots, Cambrians, and Britons, to swear fealty to him, in the same manner as the Saxon vassal was accustomed to swear to his lord. But his prosperity was interrupted by a powerful confederacy formed against him, which threatened not only to emancipate Northumbria from his authority, but even to overwhelm his hereditary government. The confederates were Constantine king of the Scots, and Anlaff the son of Sigtryg or Sihtric, who was king of Northumbria at the time of Athelstane's accession. Anlaff had received the hand of Athelstane's sister; but he drove her from his court, for which barbarous conduct the Anglo-Saxon monarch stripped him of his kingdom and ejected him from the island. Anlaff had fled to Ireland, whence he returned with a large fleet, in order to retaliate the insult of his expulsion. The remaining malcontents were the Welsh princes who had been humbled into submission, the Danes who inhabited the eastern coast from Tweed to Thames, the petty states of Cambria, and a constantly increasing host of lawless pirates and freebooters from Scandinavia.

History. 955.

Athelstane prepared with firmness and energy to meet the storm which threatened him with destruction. The armies met at Brunanburgh in Northumbria, and a battle was fought, celebrated in Saxon and Scandinavian poetry. The confederates were routed with great slaughter, and Anlaff and Constantine effected their escape with great difficulty. So complete was the overthrow, and so decisive the victory, that the remainder of Athelstane's reign was undisturbed by the rebellion of his subjects or the invasion of a foreign enemy. The throne of his ancestors was now effectually secured to him; and the Britons were so completely humbled, that to him belongs the glory of having been the founder of the English monarchy. The fame of his accomplishments, his talents, and his successes, was not confined to the insulated kingdom which he governed; it extended throughout all Christendom. With several foreign courts he maintained a friendly correspondence; and three princes, who afterwards became eminent in Europe, were fostered under his care, and restored by his aid or influence. These were Haco of Norway, Alan of Bretagne, and the son of his sister, Louis d'Outremer, so called from his residence in England. A concern in the death of a brother named Edwin is generally ascribed to him, but the story is somewhat doubtful; and if the other events of Athelstane's life, his public services and private virtues, be allowed to have any influence upon our judgment, it must be pronounced as improbable. Athelstane died in the year 940, regretted by his subjects, amongst whom he was revered as a prince alike distinguished for wisdom, justice, and benevolence.

Having left no issue, he was succeeded by his brother Edmund, who perished by the dagger of an assassin six years afterwards. The life of this king is not characterized by any events of importance. He was succeeded by his brother Edred, whose reign was short, and distinguished by no remarkable circumstance, except the complete incorporation of Northumbria with the rest of the Anglo-Saxon kingdom.

Edred died in 955, and left the throne to Edwin, who is usually styled Edwy, the eldest son of Edmund the Elder. The name of this monarch is intimately connected with that of the celebrated Dunstan, abbot of Glastonbury. The life of that individual having been already given under the head of Dunstan, we shall only mention here a few circumstances which are indispensably necessary to the complete chain of historical events. The reign of his uncle Edred had been looked upon by Edwy as a usurpation, and when he himself ascended the throne, the counsellors of the former monarch became the objects of his antipathy. He discarded them altogether, and surrounded himself with a host of young courtiers, more ready to emulate the vices of their master than to suggest prudent measures of government. At their instigation Edwy imposed

History. 959.

unjust taxes upon his subjects, despoiled the clergy, and committed other unseemly acts. Dunstan, having been one of the leading advisers of Edred, was most probably obnoxious to the young king; and at his coronation a circumstance occurred which brought the hostile parties immediately into collision. On that day Edwin, after the ceremony, withdrew from the festive board at which the nobles and clergy were regaling themselves, and retired to his own apartments. This indecorous act appears to have displeased the assembly; and Odo, archbishop of Canterbury, deputed Dunstan and another individual to bring back the king to join in their carousals. Dunstan penetrated into the private apartments of his sovereign, whom he found in company with Ethelgiva or Elgiva, his wife or mistress; the mother of the latter was also present. The two deputies forcibly tore the king from the company of the ladies, and brought him back to that of the nobles. This daring and insolent conduct of the monk towards the newly-consecrated monarch drew down upon him the royal vengeance. At the instigation of Elgiva, Dunstan was deprived of his honours, and condemned to exile. During his absence, Odo contrived to take Elgiva from her husband's residence, and send her a prisoner to Ireland, where her face was branded with red-hot irons, for the purpose of obliterating her charms; but in vain. They revived with the healing of the wounds; but on her return to England she was pursued by the opposite party, who falling in with her at Gloucester, actually hamstrung the unfortunate fair one. In a few days death released her from the vengeance of her enemies and from her own sufferings.[1] In the meanwhile a conspiracy was formed against the now unpopular Edwy; and at the head of it was his brother Edgar, who, supported by the Northumbrians and Mercians, drove the unfortunate monarch beyond the Thames. His sufferings and humiliation, however, were of short duration, for he died in 959, ere he had attained the full age of manhood. By some historians he is said to have been assassinated; others state that he pined to death for the loss of his throne, and his Elgiva, whom he tenderly loved; but all agree that his demise was as miserable as it was premature. His youth was the source of all his calamities, for it seems certain that he was only sixteen or seventeen years of age when he assumed the sceptre. He had also the misfortune to live at a very critical period. It was the commencement of that struggle between seculars and regulars which was to be maintained for many centuries thereafter. The intrusion of Dunstan into the king's private chamber was the earnest of many a bold step upon the part of the clergy. It is thus memorable as being one of the earliest instances in our history, of the putting forth of that overwhelming strength with which the church of Rome was armed, and which was destined ere long to exercise so preponderating an influence over the political affairs of every court in Christendom, whose haughtiest monarchs were soon taught to tremble at the thunder of the Vatican.

The death of Edwin put his brother and rival Edgar in peaceable possession of the whole Anglo-Saxon territory. His reign was tranquil, neither foreign enemy nor domestic broils having interrupted its quiet, so that posterity has styled him "the peaceful." The only event of a warlike character ascribed to him is an invasion of Wales. In his personal character he was distinguished alike for his religious zeal and for his licentiousness. A few facts relating to each of these may be stated here. He espoused the cause of the monks, and, during the sixteen years of his reign, erected a vast number of Benedictine monasteries. He recalled Dunstan from exile, placed the bold saint at his right hand as chief counsellor, and conferred upon him the see of Canterbury. In this situation that celebrated ecclesiastic prosecuted his ambitious schemes connected with the order to which he belonged with redoubled vigour. He expelled the clergy from the monasteries, and supplied their places with Benedictines, making the rule of their founder everywhere predominant throughout the nation.

History. 959.

We now find the church so intimately mixed up with political affairs, that some account of it is necessary for the elucidation of history. Although religious individuals had been collected in monasteries from the period of Augustin's landing in Kent, yet the order of Benedictines seems to be the most ancient example of monastic rule. Each congregation of recluses lived according to its own internal regulations, nor were the several monasteries consolidated into one community before the time of Dunstan. The Scottish or Irish, the Pictish and British churches, though in communion with Rome, were still independent of the papal see; and it was the object of the popes to suppress this independence of the different national churches; a cause which was warmly espoused by Dunstan. His policy was to enforce clerical celibacy; to expel at least all the married clergy from canonries and prebends in cathedrals, in order to make way for Benedictines; and to reduce all monasteries to the rule of the founder of that order. The opposition he encountered was formidable, and the cause of the clergy was espoused by the laity. Amongst the latter the secular priests found many powerful partizans, and the schisms of the church at last degenerated into factions amongst the people. But Dunstan was impetuous, and determined to carry through the reformation which he had begun, for he looked upon himself in the light of a reformer; and although the extension of his own power and that of his order may have been so blended with his zeal for the service of God as to deceive even himself, yet there seems no reason to doubt his sincerity. That there were many clerical abuses to be corrected, is consistent with the history of religion in all ages. The Danish invasions, and other national calamities, dispersed the clergy amongst the laity, with whose vices they doubtless became contaminated. The necessities of his situation compelled the prelate to be a statesman and an intriguer. He made some progress during the reign of Edred; in that of Edwy we have seen him checked; but in the present one, invested with the highest ecclesiastical dignities, and backed by the power of his sovereign, he appears before us under auspices which enabled him to carry his loftiest projects into execution. And he was not slow in seizing the opportunity. Not content with the ordinary engines of intrigue and supple policy, he drew upon the superstitious feelings of the time, and arrogated to himself divine intuition and the power of working miracles. He succeeded in deceiving that unenlightened age, and perhaps also himself.

The foregoing remarks may afford a key to some of the more prominent events of Edgar's reign. A national synod was held, at which the king publicly expressed his sentiments in favour of the Benedictine cause. It followed as a consequence of this, that the unfortunate seculars were ejected if they refused to comply with the enactments made by Dunstan and his party, under the

[1] There is no direct proof that this atrocity was perpetrated under the sanction of the Archbishop of Canterbury; and it is impossible to implicate Dunstan in the guilt, for he was in Flanders at the time. The deed, however, was done by the adherents, and praised by the encomiasts, of the archbishop.

sanction of the sovereign; whilst monks were everywhere received with honour, and the erection of monasteries was
975 for a time a royal mania. During the sixteen years of his reign Edgar built no less than forty-eight of these establishments.

In the midst of all this holy zeal, however, he found leisure for the indulgence of his licentious appetites. On one occasion he violently carried off a young lady educated in a convent, and made her his concubine. For this offence he was reproved by Dunstan, and compelled to do penance during seven years; but the mortifications imposed were not of a very severe character. His second marriage was connected with circumstances of a very tragical nature. The beauty of a young and noble lady having been praised to him, he commissioned Ethelwold, a favourite minister, to visit her residence, and report upon her charms. The deputy was himself captivated with the lady. He represented her in an unfavourable light to his sovereign, and married her himself; but Edgar, not being satisfied with the report, paid a personal visit to Elfrida, and, fascinated by her beauty, he procured the destruction of her husband, and espoused the bereaved lady himself.[1]

In extenuation of these delinquencies, he has been allowed the honourable distinction of having warmly patronized trade with foreigners. His commuting the tribute from Wales into three hundred wolves' heads, and his reformation of the coinage, also redound to his credit. By his orders a numerous fleet constantly guarded the kingdom from invasion, and he regularly visited his provinces in order to countenance the execution of the laws. His reign was glorious, and he seems to have converted his prosperity into ostentatious pomp. It is stated that eight kings, amongst whom were Kenneth of Scotland, and his son Malcolm of Cimbria, did him homage by rowing his barge down the river Dee.

Edgar died in 975, in the thirty-second year of his age, and was succeeded by Edward, surnamed the Martyr, his eldest son. A younger brother, Ethelred, by Elfrida, disputed the crown with Edward; but the latter was finally established upon the throne through the influence of Dunstan. His reign was chiefly occupied with disputes between the two clerical systems before mentioned, Elfrida having, on account of her son Ethelred, espoused the cause of the seculars, in opposition to Dunstan, who headed the regulars, and who was also the means of supplanting her son. The monks gained a complete victory over the seculars, who were now totally expelled from their convents. During this reign occurred that tragical circumstance which has afforded modern historians an opportunity of accusing the primate of murder. A council of nobles had been summoned to meet at Calne. During the proceedings, and just as the wily Dunstan had pronounced these words, "I confess I am unwilling to be overcome; I commit the cause of the church to the decision of God," the floor fell instantly down, and numbers of his opponents were killed and wounded. The primate, and probably his partizans, escaped unhurt, a circumstance which can 991
only be accounted for by supposing that their seat remained unmoved. Some historians charge Dunstan with having secretly loosened the floor from the walls, and affirm that during the debate the temporary props which supported it were withdrawn according to his directions. This is very improbable; but there can be little doubt that he interpreted the occurrence as a divine judgment upon his enemies, and thus wrought upon the prejudices of that superstitious age. Several heinous crimes are laid to the charge of the queen dowager, but the last was the darkest and most atrocious of all. Edward, in one of his hunting excursions, visited Corfe Castle, in Dorsetshire, where Elfrida resided with her son Ethelred. He was received with the utmost cordiality, and invited to enter the castle, but declined, requesting at the same time to see his brother, and also the favour of some refreshment. Whilst in the act of raising a cup of wine to his lips, he was mortally stabbed in the back by the orders of his stepmother. On account of his violent death he has been surnamed the Martyr.

Edward was succeeded in 978 by Ethelred, the unconscious cause of his untimely fate. When the latter attained the crown he was only in his boyhood, and throughout a long life he never rose above it. This is one of those reigns which it is painful to narrate. It was the saddest which the descendants of Alfred yet had seen, and presents a strong contrast to that of his father. Edward compelled kings to be his watermen. His son by Elfrida became the sport of traitors; and having five times purchased his crown from the roving Danes, he was forced at last to make an ignominious surrender of it to a foreign invader.

For more than a century the Northmen had formed the chief part of the population of Northumberland and East Anglia, and they now stretched their power to the utmost in order to place one of their chiefs upon the Saxon throne. In 980, and for ten years thereafter, England was insulted by a series of inroads, which, although unimportant of themselves, were calculated to excite some alarm amongst the people, when the latter contemplated on the one hand the power and audacity of the Danes, and on the other a pusillanimous monarch and an unguarded country. But these petty aggressions were followed, in 991, by the appearance of a formidable armament upon the English coast. The invaders advanced without opposition as far as Malden, where they gained a victory, and their retreat was disgracefully purchased by a bribe of ten thousand pounds. Repeatedly afterwards did the Northmen play the same game, and Ethelred make the same debasing submission, by purchasing a momentary respite from their ravages. But the very means which were employed to rid the kingdom of these invaders one year, insured their return the

[1] Dr Lingard, in his *History of England*, vol. i. p. 333, states that he is disposed to doubt this tale as improbable. "Malmesbury," says the learned and able historian, "on the faith of an ancient ballad, has transmitted to us a story probably invented by his (the king's) enemies." The story *may* possibly have been invented by his enemies, but where is the evidence, direct or indirect, that this was the case? Dr Lingard goes on to say, "it is improbable in itself, and supported by questionable evidence." Now, where lies the improbability? The tragical character of the transaction is in perfect keeping with that of the times in which it was committed; and as for the perpetrator himself, does not the abuse of the nun prove that, in order to gratify his unhallowed desires, even the religion, for the propagation of which he displayed such unbounded zeal, offered no impediment. Was the law of nature with regard to moral evil stronger in his mind than that which religion had imposed? This is much to be doubted. Nay, it may be surmised that the erection of so many monasteries was a voluntary penance which his conscience dictated him to perform, in extenuation of such crimes as those that are laid to his charge. The evidence is also said to be questionable; but if historians, and the learned Doctor along with the rest, unhesitatingly embody as historical facts the events and transactions related in similar compositions, we see no reason for making an exception with respect to the legend before us, because it happens to stand in the way of a favourite hypothesis. If we take one we must take all, exceptions being made where there is direct contradiction by more authentic evidence, which is not the case in the present instance. Sir James Mackintosh observes, "William of Malmesbury, who might have known the counsellors of Edward the Confessor, relates the incident on the authority (not to be despised) of a Saxon song. The same story is told by a later chronicler called Brompton (*Dec. Scrip.* 865), at great length, and with particulars characteristic of barbaric manners."

History. 992.

next. Treason, famine, and disease, also aggravated the calamities which overwhelmed the nation. Amongst the instances of defection, that of Alfric, earl of Mercia, demands particular attention. On account of his misconduct he had been deprived of his government, but had recovered it again through the influence of his friends. In 992, a meeting of the witenagemote took place at London, where it was resolved to put the kingdom in a posture of defence, by constructing a powerful fleet, and manning it with picked men. This was accordingly done, and the command of it conferred upon Alfric, with another nobleman and two prelates. Their commission was to surprise the Danes at some part where they could be surrounded; but this judicious scheme was foiled by the treachery of the commander, who not only gave the Danes notice of the intentions of the English, but consummated his perfidy by secretly joining them. He urged an immediate flight; but in the pursuit his vessel was taken, though the traitor himself escaped. The king revenged himself upon Alfric, by ordering his son Algar to be deprived of his eyes; an act as barbarous as it was useless.

This bold exertion on the part of the invaded compelled the Danes to transfer their arms from the south to the north of England, where they extended their ravages; but in 994 appeared two new and more powerful chieftains, Sweyn, king of Denmark, and Olave, king of Norway. With ninety-four ships they sailed up the Thames, and, although repulsed at London, they succeeded in ravaging several counties. But another humiliating subsidy redeemed England from their grasp; and, what is more astonishing still, Olave was honourably received at the court of Ethelred, where he pledged his word never to molest England more. This promise is only remarkable inasmuch as it was faithfully kept. The army of his companion Sweyn, however, continued to occupy the country, to which in course of time it became almost naturalized. That it should remain inactive was not to be expected; but that with impunity it should have been allowed to despoil provinces, displays a want of firmness, courage, and national spirit, which seems unnatural to the island, and can only be accounted for by supposing the existence of a weakness almost amounting to imbecility in the sovereign or his counsellors.

In 1002, Ethelred having lost his first wife, who bore him ten children, married a Norman princess, who assumed the name of Elgiva. The same year became memorable in the history of England for the perpetration of a crime of as black a dye as ever darkened the annals of any people. This wicked act, which rose out of a mischievous policy, is known by the name of the Massacre of the Danes. On the 13th of November, the festival of St Bride, the unsuspecting Northmen, with their wives, children, and all belonging to them, were cruelly put to death by a royal warrant. The details of this fearful transaction are too horrible to be related. Suffice it to say, that no place, however sacred, saved the victims from their pursuers; and that when they fled to the churches for shelter, they were slaughtered in crowds around the altars. One painful episode is interwoven with this tale of blood. Gunhilda, the sister of Sweyn, king of Denmark, who was wedded to an English earl, saw her husband and children massacred before her eyes, and was herself afterwards beheaded. It is related by all historians, that in the agonies of death she foretold the vengeance which would descend upon the English nation for the barbarous act which it had committed; and the prediction was realized, as we shall hereafter see.

The calamities of England seemed now to thicken as the atrocities of its ruler grew darker. Common pity for the failings of humanity would lead us to pardon Ethelred's pusillanimity; but this dark deed has affixed a blot to his scutcheon too deep for time ever to wash away. Sweyn was not slow in revenging the fate of his countrymen; and, through negligence and perfidy on the part of England, he succeeded in ravaging the island, for several years. almost with impunity. In 1007, thirty-six thousand pounds of silver abated his thirst of revenge. Two years afterwards the most powerful armament which had yet obeyed the flag of England was collected at Sandwich; but treason again paralyzed its operations. The captains abandoned their vessels, which were steered up the Thames by the mariners. "Thus," say the annalists, "perished all the hopes of England." The surrender of sixteen counties, and forty-eight thousand pounds, stayed for a short period the rapacity of the Northmen. The picture which the now fallen and devoted England presents, it is painful to contemplate. Accumulated treasons and defeats had unnerved the courage of the natives; whilst the numerous victories of the Danes had swelled their pride, and inspired them with a preposterous idea of their warlike powers. Many fortified cities withstood all their assaults; but the open country was abandoned to their rapacity. Systematic destruction and spoliation was their principle; and the fields, deserted by the husbandmen, ceased to yield the necessary supplies of food, so that the Danes themselves were compelled to quit the island in search of provisions. Taxation, direct and annual, which must be traced to this period, weighed also upon the energies of the people, and materially increased the now almost universal discontent. In the midst of this ignominious submission and disaffection, it is pleasing to record instances of magnanimity, and painful to reflect that these were so few in number. The Archbishop of Canterbury having been made a prisoner by the Danes, was offered his liberty for a moderate ransom, on condition that he would advise Ethelred to pay them heavy sums of money as a largess. "I have no money," he replied, "and I will not advise the king to dishonour himself." Still they persisted; but the dauntless prelate remained unshaken. The barbarians condemned him to death; and he was immediately assailed with bones, horns, and other remains of a feast in which they had been indulging. "Gold, bishop; give us gold," they exclaimed, as they dragged him forth; but he remained unmoved, and having been felled to the earth with the rude missiles which were showered upon him, he received a mortal stab from the hand of a man whom he had himself baptized.

History. 1013.

Sweyn made his last incursion into the country in 1013. Terrified at the universal disaffection, Ethelred fled at last to Normandy, whence he returned on hearing of Sweyn's death, which occurred shortly afterwards. The latter was succeeded by his son Canute; for the Danes would now appear to have put in a claim for the sovereignty of the whole country. Ethelred was recalled by the English chiefs, who exacted a promise from him that he would govern with less tyranny than formerly; and pledges were also interchanged between the Danes and English. But a contest soon ensued between the two parties; and although Ethelred succeeded in repeating upon a small scale that system of treacherous massacre for which he had so severely suffered, yet Canute maintained his superiority in open warfare, and took a barbarous revenge upon the hostages in his hands, for the murder of his friends. Treason again added a fearful contribution to the accumulated evils which surrounded the unfortunate Ethelred. His son Edmund, surnamed, from his hardihood, Ironside, vainly attempted to make head against the Danes; for Canute penetrated to York, where he was joined by the Earl of Northumbria and a number of the people. The country was now a prey to two contending armies; but just at this crisis it was reliev-

History. 1016.

ed from its greatest enemy, Ethelred, who died towards the end of 1016, worn out by care and disease.

Edmund Ironside was immediately chosen king by the English; and if the exertions of one man could have saved the country, this achievement would have been performed by the new king. During his short reign, for it extended to only a few months, he gave proofs of bravery and ability equal to any exigency, and worthy of a happier fortune. The first struggle between him and Canute was for the possession of London, which was held by the English. During the siege Edmund fought two battles in the provinces, one of which took place at Scearston, and is celebrated by our annalists. Twice the darkness of night came to the relief of the exhausted armies, which had both suffered severely; but the dawn of the third morning showed the result to be in favour of the English. Canute, however, had taken advantage of the night, and marched upon London. Not long afterwards another battle was fought, in which Edric, a traitor thrice steeped in infamy by his defection, played the game of victory into the hands of Canute. After this calamitous event the greatness of Edmund's soul became more conspicuous. Although a numerous army had again rallied around his standard, he shuddered to lavish more of his country's blood in this murderous warfare, and challenged Canute to decide their quarrel by single combat. Whether this proposal was accepted or not, is matter of uncertainty; but at all events a pacification was shortly afterwards agreed upon, and England was divided between the rivals; the north being given up to Canute, whilst Edmund retained possession of the south. The latter, however, died shortly afterwards; and there is reason to believe that he perished through the machinations of the perfidious Edric.

Edmund left two sons, infants; but by the unanimous voice of the nation Canute obtained the sovereignty of England. This remarkable prince was only twenty years of age when he assumed the reins of government. His qualities as a monarch were of a very high order, not unalloyed, however, with the ferocity natural to the Northmen of the period. The first object of his policy was the removal of the children of the two preceding kings. Some of the sons of Ethelred were slain, and the rest consigned to banishment; whilst those of Edmund were sent over to Sweden, for the purpose of being dispatched. But their fate was averted by the prince to whom they were conveyed. He sent them both to the king of Hungary, by whom they were educated in a manner befitting their station. One died in his youth, the other married the daughter of Henry, the emperor of Germany; and their issue was Edgar Atheling, who will be mentioned hereafter.

Canute divided the kingdom into four governments. He retained Wessex to himself. East Anglia was conferred on a chief named Thurchil, who had formerly distinguished himself; and Eric and Edric were continued in Northumberland and Mercia. But the latter shortly afterwards received the full reward of his crimes and perfidy. At a Christmas festival celebrated in London, he had the audacity to boast of his services, when Canute ordered him to be cut down, and his body thrown into the Thames. The Danish king had embraced Christianity, and also taken to wife Emma, widow of Ethelred. The profession of the former removed the main barrier between his English and Danish subjects; and his espousal of a royal female was no doubt intended to conciliate the affections of the Saxons; and it seems to have had a considerable effect in this respect. The other events of this reign will be found related under the head of CANUTE. He died at Shaftesbury in 1035, and was interred at Winchester. By his wife Emma he had a son and daughter; the former called Hardicanute, or Canute the Hardy. But previously to his marriage he had by another lady two sons, named Sweyn and Harold. The former was installed in the sovereignty of Norway, and the latter ascended the throne of England.

History. 1051.

Harold was not entitled to the crown; for it had been provided in the marriage settlement of Emma, that the issue of Canute by her alone should reign; yet he being on the spot, succeeded in obtaining the sceptre as well as the treasures of his father. Edward the son of Ethelred, certainly the legitimate sovereign of the kingdom, made an attempt to obtain it, but proved unsuccessful. His brother Alfred renewed the enterprise, which proved fatal to him and to most of his followers. This prince received a letter, which purported to be from his mother, inviting him to come over and take possession of his father's dominions. The proposition was flattering, and in an unlucky moment he yielded to it. Having landed with six hundred followers, he was treacherously made prisoner, along with his companions. Every tenth man was set at liberty, a few more were reserved as slaves, and the remainder were massacred and mutilated with the most capricious cruelty. Prince Alfred himself was deprived of his eyes; and this shocking barbarity soon afterwards terminated in his death. The unfortunate sufferer was the dupe of a forgery; and the whole villanous transaction seems to have been planned by Harold, and executed by his minions, particularly Earl Godwin. This remarkable individual, according to the only account of him which we possess, was the son of a Saxon herdsman. In his youth he had assisted Ulfr, a Danish chieftain, to make his escape to the ships of Canute. The Northman took him under his charge, and by successive steps he rose to the dignity of a Jarl, and to the possession of power little less than sovereign during three reigns. The atrocious deed of blood above related is the only event of importance associated with the name of Harold the First. He died in 1040, and was succeeded by Hardicanute, his brother by the half blood.

This sovereign reigned about two years; and the little that is recorded of him is of a very mixed character. He came over from Denmark, breathing revenge against the murderers of Alfred, and even went so far as brutally to insult the lifeless remains of Harold. Godwin stood prominently forward as an object of punishment, but a splendid present turned aside the shaft of vengeance. Others also escaped by appealing to his avarice, which seems to have been his ruling passion. Edward the son of Ethelred was kindly and honourably received at his court—a noble act of generosity; yet the author of it died of intemperance at the nuptial feast of a Danish lord.

Edward, surnamed the Confessor, the surviving son of Ethelred, was chosen king of England in 1042. He was a weak and feeble prince, and incompetent to the task of vigorous government; yet the commencement of his reign was characterized by an act of severity. He despoiled his mother Emma of her property, and deprived her of her influence. These proceedings were prompted by the antipathy which she bore to the king, and by her lukewarmness in not punishing the murderers of her son Alfred, of whose blood it was even whispered she was not entirely guiltless. The weak and irresolute character of the king threw the power entirely into the hands of the three noblemen who divided the Saxon territory amongst them, Siward earl of Northumberland, Leofric earl of Mercia, and Godwin earl of Kent, whose daughter, Editha, Edward had been induced to marry. Godwin was by far the most powerful of the three; for besides his own territory in Wessex, his two sons, Sweyn and Harold, held large domains northward of the Thames. In 1051 he at last presumed to bid defiance to his sovereign and son-in-

History. 1051. law. Edward, who had sojourned a long time in Normandy, where he was well treated, when he ascended the throne invited the guardians and friends of his youth to accompany him to England. They accordingly flocked to him in great numbers, and received ample preferment. One of them, named Robert, obtained the primacy, at that time the station of highest dignity and power. Amongst those who resorted to England was Eustace count of Boulogne, who had married Edward's sister. At Dover, one of Godwin's towns, a foolish affray took place between the followers of the count and the English. This circumstance gave vent to the popular jealousy of the people against foreigners. Godwin assembled a force, and claimed the surrender of Eustace; but the latter was supported by the king, who ultimately succeeded in driving Godwin and his sons into exile. The star of Godwin seemed now to have fairly set; but just at this moment there arose another of far more disastrous omen to the Saxon line. William duke of Normandy came to England with many of his followers, on a visit to his cousin Edward. He was received with great honour, and loaded with presents when he returned to his own country.

Had the illustrious stranger never risen to be ruler of England, his first visit to it would probably have been passed over by historians with a simple relation of the event. But his singular fortune has induced some writers to find in it a clue to his subsequent proceedings. It is impossible to conjecture what may have passed in his mind upon this occasion. On the one hand he saw, that in the course of a few years, the crown would soon become vacant, for its possessor was now stricken in years, and, moreover, childless. On the other hand, there stood in the way of his claim to it, first of all, Edward, the son of Edmund Ironside; then his son Edgar Atheling, a weak prince, however; and afterwards the brothers of Edward's queen. Under such circumstances his vaulting ambition may have led him to indulge in aspirations to the crown; but only a vague probability of ultimate success must have been awakened in a mind possessed of such high reflecting powers as that of William the Conqueror. Too many obstacles stood in the way of his fostering any sanguine hopes of acceding to the throne of England; and it is certain that the objects of his first visit were pacific. It appears highly probable that his politic foresight might induce him to take measures for securing the crown after the death of Edward the son of Ironside, which took place some years subsequently to his visit to England; and a conjecture may be hazarded that it was immediately after the demise of his brother's son that the Confessor made a promise to William of leaving him the crown. That such a promise was given was afterwards alleged by the Conqueror, as we shall see when he comes before us as a claimant of the sovereignty. In about a year after this the Godwins were restored to their honours and estates; and Editha, who had been repudiated by the king, was called from her prison to the throne. She was innocent of any participation in her father's guilt. The annalists of the time represent her in the most amiable light, and as incapable of devising evil either against her husband or any other individual. On his re-instalment in his earldom and possessions, Godwin succeeded in inducing the king to outlaw Archbishop Robert and all the Frenchmen; and not long after he died ripe in years and in crimes. In 1055 Siward followed him to the grave; and two years afterwards expired Leofric, the wise and powerful duke of Mercia, who was succeeded in his dukedom by his son Algar. Tostig, brother of Harold, received the earldom of the former; but in a few years afterwards (1065), he was deposed for his cruelties, and his sovereignty conferred upon Morcar, son of the Duke of Mercia.

Soon after these transactions, the pacific monarch of England began to sicken. When he saw his end approaching, he ordered the magnificent church of St Peter at Westminster, which he had built, to be consecrated with solemnity and splendour. He died two days after, on the 4th or 5th of January 1066, in the twenty-fourth year of his reign, and was interred in the church which he had so recently dedicated. He left no issue; for he had taken a vow of continence for life. Edward Atheling, the only surviving son of Edmund Ironside, had landed from Hungary with his wife and children, for the purpose of being proclaimed heir to the crown; but shortly after his arrival in London he expired, bequeathing his claim to his son Edgar. History. 1066.

Edward the Confessor presents himself to us only in one character, that of a royal monk. His piety and gentleness might have adorned a cloister, but, unallied with those sterner virtues which fit a monarch for wielding the sceptre with firmness and energy, they rendered him unfit for ruling, except under the influence of able counsel, which he had the good fortune to possess during the greater part of his reign. Abject superstition will unnerve even a strong mind, and to a weak one it imparts a character of childlike feebleness, and forms such an individual as Edward. But he had many amiable qualities, which would have redeemed even greater weaknesses than those with which he is chargeable. He loved his people much; he was averse to the imposition of taxes, some of which he abolished; and his charities were frequent and extensive. His subjects repaid his attentions by lamenting his loss as a national misfortune, and consigning his memory to the veneration of posterity.

The day which witnessed the funeral of Edward, saw the coronation of Harold, the son of Godwin. A report had been circulated that the Confessor had appointed him his successor, which greatly conciliated the chiefs; indeed the only opposition which he experienced was from his own unnatural family. On Edgar Atheling, the last surviving prince of the house of Cerdic, was conferred the earldom of Oxford, in lieu of the crown. Tostig, the brother of the king, was a competitor for the crown. Harold Hardrada, king of Norway, promised him his support, and the politic duke of Normandy did the same. In Flanders he was permitted to raise an army, with which he landed in Northumberland; but he was defeated by Morcar, on whom the earldom of the province had been conferred. The discomfited Tostig fled to Malcolm, king of Scotland, where he was well received. The Caledonian monarch had himself been sheltered at the English court during the usurpation of Macbeth, and was established on the throne of his ancestors by the aid of England. As a grateful return for the attentions he had received in that country, he always readily welcomed the malcontents who fled from it. The arrival of his Norwegian ally recalled Tostig from his exile. They joined forces at the mouth of the Tyne, and marched upon York, in the neighbourhood of which city the Saxon army sustained a defeat. But this was only a prelude to the grand struggle. Harold, the king, notwithstanding the necessity under which he lay of watching the south-eastern extremity of the island from a still more formidable rival, collected a considerable army, and marched with promptitude and secrecy to meet Tostig and his Norwegian ally. So rapid had been the movements of the king that he took the enemy in some degree by surprise. They, however, retired upon Stamford-bridge on the Derwent, where they drew out their line of battle. The contest which ensued was bloody, and long of doubtful issue. For a while the firm array of the Norwegians bade defiance to all the efforts of the English cavalry, which, accustomed to charge in detached masses,

fell in this dispersed state almost harmless upon the bristling rampart of Scandinavian spears. The king of Norway, conspicuous by his blue tunic and glittering helmet, made the most heroic exertions; but victory forsook his standard; a fatal dart pierced his throat, and he fell lifeless to the ground. Tostig assumed the command, and after a desperate effort to turn the fortune of the day, he perished, with the flower of the Norwegian army. This victory, which is memorable on account of the dreadful slaughter that distinguished it, was gained on the 25th of September 1066. It must be recorded to the honour of Harold, that twice he offered peace and pardon to his rebellious brother, once before and once during the heat of battle, when the Norwegian had fallen, but both times these offers were refused. Three days after this conflict William duke of Normandy landed in England, and Harold had to prepare for another desperate struggle to retain the crown. It will now be necessary to examine how far the pretensions of the new competitor for it were legitimate.

This celebrated claimant to the sceptre of England was the descendant of Rollo, a renowned Vikingr or Sea-King, who flourished at the beginning of the tenth century. Rognvalldr, the father of Rollo, was one of those earls appointed by Harold Harfager, or the fair-haired, to guard his conquests. He had two sons, Thorer and Rolfr, better known by his more celebrated name of Rollo.[1] The progenitor of William the Conqueror was expelled from his country on account of a violation of the law which forbade freebooters, under pain of death, to destroy cattle on the Norwegian shore. Driven from his paternal shores, he resolved to seek for a kingdom elsewhere; and after much successful valour he succeeded in establishing a Scandinavian state in France. Rollo proved himself a prince worthy of a kingdom, and his acquisition in course of time assumed the name of Normandy. His exertions for the improvement of his dominions, the civilization of the rude Northmen, and the humanizing of their minds to the love of order, justice, and the arts of peace, class him with those illustrious individuals who have proved themselves benefactors of the human race. He died in 931, and was succeeded by his son William. After two others, Robert the Magnificent, or the Devil as he was perhaps more appropriately designated, succeeded. He was father to the duke, who now appears before us as a competitor for the English throne. William was an illegitimate child by a damsel of humble condition, of whom his father was enamoured, but could not wed during the lifetime of his duchess, the sister of Canute. Like their northern progenitors, the nobles of the Norman duke were careless of the distinction between concubinage and wedlock, so that on the death of Robert in 1035, William, although then only eight years of age, was triumphantly placed upon the ducal throne, which he filled with renown for fifty-three years.

The circumstance of numerous Norman barons having settled in England during the reign of Edward the Confessor, who was the grandson of a duke of Normandy, has already been noticed; as also the visit paid by William to the childless monarch. It was afterwards asserted by the Duke of Normandy, that upon one occasion, probably that to which we have already alluded, Edward had bequeathed to him the crown of England. He also alleged a testamentary bequest, as well as Harold. Both were alike destitute of any claim founded on the modern principles of hereditary descent, but both by consanguinity made out a species of right to inherit; William as the grand uncle of Emma the king's mother, and Harold as the king's brother-in-law. The claims of the champions were therefore nearly balanced, and seem to have contented their partizans; the sword alone could decide to whom the real title should belong.

In the mean time the claim of Harold suffered considerably on account of a circumstance which occurred a short time before the demise of the late king. The Saxon had been shipwrecked in France, but obtained leave to proceed to Normandy by alleging that he was intrusted with some communications to Duke William. That prince received him kindly, and imparted to him the hopes which he cherished of obtaining the English crown. He received a promise of aid from Harold, and by an artifice succeeded in making him swear fealty to his cause. Underneath the missal on which the Saxon had sworn were concealed various sacred relics, such as the bones of saints and martyrs, and thus he had unconsciously bound himself by the most solemn oath. When the struggle came, Harold urged the plea of compulsion as releasing him from any obligation to keep his vow. Abhorrence of oath-breakers, however, is characteristic of a superstitious age; and whilst the circumstance materially weakened the cause of Harold, it strengthened in a corresponding degree that of his rival. There is also every reason to believe that it was the principal means of enabling William to obtain from the holy see a declaration in favour of his enterprise. At such a period a bull from the pope was itself worth an army, and this the adventurer not only obtained, but also a consecrated standard, a ring, and a lock of his holiness's hair.

William now set busily to work in preparing the means of offensive aggression. When his purpose was known, he was speedily joined by all the young knights of the neighbouring countries who sought fortune or renown, and by all the freebooters whom the hope of spoil allured to his standard. With an armament more formidable than the western nations had yet witnessed, he accordingly put to sea. Annalists have greatly exaggerated the number of his troops; for altogether they did not probably much exceed twenty-five thousand men. With this army he landed without opposition at Pevensey, in the county of Sussex, as has already been observed. He made no stay at that place, however, but proceeded immediately to Hastings to procure provisions. Harold, apprised of the arrival of his most dreaded enemy, flew to attack him. William, informed of his victory and advance, was counselled by some to remain in his entrenchments, and not to hazard an open engagement. But the mind of the future conqueror was not liable to the agitations of fear. He had thrown his life upon a cast, and was resolved to stand the hazard of the die. In this emergency the conduct of Harold has been severely censured. He appropriated to him-

[1] In the *History of England* by Sir James Mackintosh (vol. i. p. 90), the following sentence occurs:—"One of the sons of Roguevald, called in the Icelandic poems *Hrolpt*, better known to us by the name of Rollo, had, for reasons unknown to our authorities, been excluded from all share in his father's domains, and had no resource but piracy." The reason of his exclusion was in all likelihood his being a younger son. We have already noticed, that amongst the Northmen of this period an absurd law obtained, by which all but the eldest son were excluded from any participation in the property left by the father. By this pernicious arrangement the younger branches of families were driven to seek their fortune upon the sea. It is certain that Roguevald left two sons; it is also next to certain that he would observe the law of the land as it then existed. Now, the question comes to be, which of the two was the first born. There is no direct evidence upon the point, but the circumstance of Thorer's name having always the precedence when the brothers are mentioned together, and also that of Rollo's piratical exploits, whilst there is no mention made of his brother in that capacity, seem to determine the point that the progenitor of a future royal family of England was the youngest son;—and thus the difficulty is explained.

History. 1066.

self all the spoils of the late battle, which added to his unpopularity; whilst the death of his brother was by common report imputed to him. On his march against William, a considerable portion of his army deserted him, and their place had to be supplied by raw and undisciplined levies. When the two rivals were near enough to interchange messages, the Norman offered Harold the choice of abdication, of single combat, or of appeal to the pope. These propositions being rejected, he was then offered Northumberland for himself, whilst Kent would be conceded to his brother Gurth; but the latter proposal shared the fate of the former one; upon which William declared his intention of giving battle to his rival, whom he looked upon and designated as a liar and a perjured wretch, excommunicated by the holy father. He even expressed astonishment that an individual conscious of such guilt as that with which Harold was chargeable should venture his person in battle. We are told that such a feeling also prevailed in the English army, and that the king was advised by his brothers Gurth and Leofwin to withdraw, whilst they would lead on the battle. Harold, however, only smiled at their apprehensions, and expressed his resolution of commanding the army in person.

On the morning of Saturday the 14th of October William advanced to the attack of the Saxons, after having solemnly heard mass and received the sacrament. The previous night is also said to have been passed in devotion, whilst songs and revelry resounded throughout the Saxon camp. The spot which Harold had fixed upon for this important contest was a piece of rising ground about eight miles inland from Hastings. It was open towards the south, and was covered at the back by an extensive wood. On the front of the declivity the troops were arranged in one compact mass, in the centre of which floated the royal banner, with the king and his two brothers near it. On an opposite hill stood William in front of his warriors, with the relics upon which Harold had sworn hung round his neck, and the consecrated standard waving by his side. After a short address to animate his soldiers, he advanced upon the enemy, shouting the national war-cry "God is our help;" whilst the cry of "Christ's rood, the holy rood," rose from the adverse ranks. The impetuous onset of the Normans was received by the English with their battle-axes, with which they broke the lances and cut the coats of mail, on which their opponents placed great reliance. The confidence of the Normans began to waver, and the left wing, both horse and foot, actually gave way. With eager rashness the English pursued, and thus exposed themselves to the hazard of being cut off; for William with dauntless fortitude and presence of mind had succeeded in rallying his fugitive bands. The attack was renewed, and again the English repulsed it. The duke had now recourse to an artifice which ultimately proved the destruction of the enemy's army. By a feigned flight he allured a body of them from their strong position, and, whilst the latter too eagerly pursued, he turned upon them with his cavalry, and hewed them in pieces. Twice was this stratagem repeated, and each time with perfect success. Still the main body of the English presented an unbroken rampart of shields, against which the mass of Norman chivalry for a long time was hurled in vain.

During the conflict both leaders gave proofs of personal bravery and skill worthy of the crown which the one was combating to retain and the other to wrench from his grasp. William had three horses killed under him, and hand to hand he had grappled on foot with his adversaries. A little before sunset Harold, both of whose brothers had already fallen, received an arrow in the eye, which penetrated to the brain. His fall relaxed the vigour of the English. Their lines were penetrated, their standard taken; and a panic having seized upon them, they broke and dispersed through the wood, whilst darkness closed upon the spoils of the field and the hopes of the Saxons.

History. 1066.

Thus ended the battle of Hastings, memorable in various respects, first, as introducing a new dynasty of monarchs to rule the southern part of Britain; and secondly, as opening up to the inhabitants of the island the means of a more extensive intercourse with the continent than they had ever yet enjoyed. By this means were introduced into Britain those modes of life, manners, customs, and institutions which were at the time considered as characteristic of civilization and refined society; and henceforth England was destined to take a large share in the transactions and fortunes of the continental powers, perhaps ultimately for the mutual benefit of all parties.

On the morning after the battle, the victors, having stripped the bodies of the slain, pranced wantonly over them with their horses. The mother of Harold, like another Andromache, begged the corpse of her son from the conqueror; but whether her maternal request was complied with or not is a matter of great uncertainty; for upon this point our annalists are either contradictory or ambiguous. By one party it is asserted that the corpse of the fallen monarch was interred upon the beach; by another that it was given up when demanded, its weight in gold having been offered as a ransom. Perhaps both are correct; for it is probable enough that it was first buried on the shore, and afterwards exhumated at the request of the mother. Without entering into any speculation connected with the Norman conquest, we may simply remark, that in order to interest the reader of English history, and excite commiseration and pity for Harold, he has, by a number of historians, been invested with talents, virtues, and accomplishments which he did not possess in a degree sufficient to command the entire affection of his countrymen during his life; whilst his death has also been deplored with unnecessary regret, as a sort of national loss. Where the stakes are equal, and the game a fair trial of strength and dexterity, sympathy will always side with the loser. Over his opponent Harold had the advantage of fighting for his native land against a foreign invader; but it must be observed that his own aggrandisement and the independence of the nation were inseparably connected, and that in pursuing the one he was combating for the other.

Before entering into the subsequent history of the conqueror's proceedings, it will be necessary to pause and take a rapid glance at the Anglo-Saxon institutions before they were supplanted by the system which the successful invasion of the Normans was destined to introduce.

The Anglo-Saxon king, without possessing despotic sovereignty, was in dignity, property, and power elevated far above the level of the rest of the nation. He was elected by the assembly called the *wittena-gemote*, a meeting of wise or prudent men. This was the great council of the nation, and seems to have resembled what our modern parliament would be if lords and commons mingled together and debated in one house. It was composed of the prelates, earls, and a great many thanes or considerable proprietors of land, a class similar to our modern gentry; so that the Saxons may be said to have possessed the elements of a free and popular government, though as yet in a rude and chaotic state. This supreme judicial and legislative assembly was convened by the king, and held its meetings on the great festival days of the church, such as Christmas. But these were not confined to such seasons, being called together according as circumstances required. Besides electing the king, and presiding at his coronation, they assisted him in making laws and treaties, in military preparations, in administering justice, and the other affairs of government. Their power was considerable, but it de-

History. 1066.

pended in a great measure upon the character and capacity of the sovereign. The highest officer in the kingdom was the ealdorman; he was chief of a shire, and had great judicial powers. An eorl was the next dignity, which remained separate from the former until towards the close of the Anglo-Saxon period, when the title of ealdorman seems to have been superseded by that of eorl; under them were other officers, whom it is unnecessary to particularise. There was of course a wittena-gemote to every kingdom; and when all the principalities merged in Wessex, and gave rise to a single one for the whole country, the monarch occasionally held *shire-gemotes*, or county meetings, where the laws made by the king and his counsellors were proclaimed, and being acknowledged and sworn to, became binding on the whole nation.

The Anglo-Saxons were divided into freemen and slaves. But there was a third class, such as bordars, cottars, and others, who were cultivators of the soil, and, ranking probably in the lowest order of freemen, were scarcely reduced to the degrading level of slaves. As far as has yet been ascertained, the class which was subject to the most complete thraldom was small in comparison with those who enjoyed superior privileges, probably about one in seven. The Anglo-Saxons paid some attention to the cultivation of the land, which was held by various tenures, and liable to certain burdens, which varied in kind and quantity. Military service, which consisted in providing a certain number of armed men when public safety required them, was one of these. The other two great services were the constructing or repairing of bridges, fortresses, and walls. Besides these, the sub-proprietors of land were more or less liable to many other burdens. With regard to their conveyances, we have several of their grants of land without any pecuniary consideration; of their conveyances on purchase; of their deeds of exchange; of their testamentary devises, and their leases. These were, in the early periods of Anglo-Saxon history, short and simple; but in grants of a more recent date the general words are nearly as numerous as in our present deeds.

The supreme legal tribunal was the wittena-gemote, which, like the present House of Lords, was paramount to every other. There were also shire-gemotes and burgh-gemotes, so many yearly meetings of which were strictly enjoined upon those who composed them. Much of their judicial proceedings rested upon oaths, and perjury was therefore severely punished. For the various breaches of the law the punishments were commonly pecuniary. In the case of murder, the amount, which was partly levied by the state as a penalty, and partly granted to the family of the deceased as a satisfaction for the loss of their relative, was proportioned to the rank of the murdered man. Persons accused of crimes had occasionally to pass through an ordeal of hot water or hot iron, of which they had their option.

There were many popular institutions which rendered the king subordinate to the community. The meetings of the people at the various courts, from the folkmote of the hundred, to the wittena-gemote of the nation, contributed to foster the principles of equal law and of popular government. From the Anglo-Saxons we derive our language, the names of the most ancient officers among us, and those of the greater part of the divisions of the kingdom, and of almost all our towns and villages.

In their domestic habits the Anglo-Saxons were social, and loved the pleasures of the table. Their food was that mixture of vegetable and animal diet which always marks the progress of civilization. Ale and mead were their favourite drinks, and wine was an occasional luxury. They had become so far acquainted with the conveniences of civilized life as to display both variety and vanity in adorning their persons. Their dwelling-houses seem to have been small and inconvenient, although they were both expensive and magnificent in their ecclesiastical buildings. Amongst the Anglo-Saxons females were very respectfully treated, and occupied the same independent rank in society which they now enjoy. The trades and mechanical arts had made considerable progress, and even foreign commerce was carried on and considered as a highly honourable calling. With regard to their circulating medium, it may be shortly stated, that they had their pounds, shillings, pence, and farthings, exactly as we have at present. Learning, except amongst ecclesiastics, was neglected; and with regard to literature, little can be said with certainty, for the monuments of this kind which they have left us, except what is historical, have not yet been examined with sufficient care.[1]

The conquest of England did not altogether terminate with the battle of Hastings. London and other important towns were put in a posture of defence, whilst a numerous fleet had assembled at Dover to interrupt the proceedings and distract the attention of the invader. Edgar, the legitimate heir to the throne, appears to have been either crowned or acknowledged as sovereign at London, where the two powerful earls Morcar and Edwin, with the loyal inhabitants, resolved to make a desperate stand against the advancing foe. William, however, instead of attacking the city, chose rather to lay waste the country, which he did most effectually, consigning to the flames what could not be forcibly removed. He now appears before us in a character somewhat new. Formerly he had combated for the crown against an individual who, according to all modern notions of legitimacy, had no more right to it than himself; but in the present instance he was attempting to snatch it from the brow of him who alone had a hereditary claim to wear it. On this account the atrocities committed by his troops are justly contemplated with horror, whilst the disposition to palliate them is proportionally lessened.

William, however, was the candidate favoured by the see of Rome, and the bishops interfered in his behalf. Stigand, the metropolitan, was the first to throw himself on the mercy of William, whom he met as the conqueror crossed the Thames at Wallingford, and swore fealty to him as his sovereign; others followed his example, as did Edgar, Edwin, and Morcar upon the part of the nobility. The crown was offered to him, and he was formally invested with it in Westminster Abbey, on Christmas 1066. During the ceremony a tumult arose which made the stout heart of the conqueror to tremble beneath its iron mail; and, had an English force, led by any competent commander, and capable of making head against the Normans, appeared at the moment, it might have cost him his crown and his life. Whilst, by loud acclamations, both English and Normans expressed their willingness to have William for king, his troops set fire to the houses, and commenced the plunder of the city. The coronation service was hastily concluded, and the insurrection quelled without much difficulty, although the English looked upon it as a bad omen, and William as a most unfortunate occurrence. It was his interest to propitiate the affections of the people whom he had now been appointed to govern, and he anxiously wished to do so. In explanation of this occurrence, it is usually alleged that the Normans mistook the acclama-

[1] Turner's *Anglo-Saxons*, vol. ii. *passim*. Mackintosh's *England*, vol. i. p. 71.

History. 1066.

tions of those who shouted within the church for an alarm of the English to rise in revolt. But if this had been the case, why did they not instantly fly to the rescue of their king, instead of spreading themselves about and firing and pillaging the city? His safety was surely their first care; for had he fallen, their fate was inevitable. The whole unquestionably originated in the desire of the troops for sack and pillage.[1]

Hitherto William had been called the Bastard; from this period he obtained the surname of the Conqueror, a term which at the time was employed to designate a person who had sought and obtained his right, as well as a subjugator. It was necessary for William to maintain a strong military force in order to compel the obedience of his subjects; and he could only feel himself secure surrounded by his trusty Norman barons. But the duration of their services being limited to a certain term, they naturally expected to be released from their engagements, and re-conveyed to their country, when the period of servitude had expired. In order to encourage them to remain, he put into their hands the strongholds and principal towns of the kingdom, whilst all the conquered territory of the English, which he had at his command, was likewise distributed amongst them. Having thus put his dominions in a secure posture, he embarked for Normandy, carrying along with him Morcar, Edgar, and Edwin, and leaving the chief management of affairs in England in the hands of William Fitzosbern, a Norman baron, and Odo, bishop of Bayeux, the son of his mother by a plebeian husband. During the absence of the Conqueror, the Saxons began to mutter threats of vengeance, and even went so far as to enter into a conspiracy to cut off the Normans as their forefathers had done the Danes. It appears, from the testimony of several credible annalists, that the oppression which the English suffered at the hands of the insolent soldiery was most galling, and called loudly for retaliation. These alarming rumours crossed the channel, and reached the ears of William, who hastened from his continental dominions, and, landing in England in December 1067, made a sort of second conquest of that country. The Saxons of Devonshire, joined by the neighbouring Britons in Cornwall, had thrown off their allegiance to him, and against them he first turned his arms. They made a gallant stand; but William having reduced Exeter, succeeded in breaking the spirit of resistance for a time. About this period, Edgar, with his mother and two sisters, having embarked for Hungary, were driven by a tempest upon the coast of Scotland. That country was at the time governed by Malcolm, surnamed Ceanmore, who gladly received the fugitives, and made them a return for that kindness which he had himself experienced under similar circumstances at the English court. Many Saxon nobles followed Edgar, who, with subsequent emigrations of disaffected Normans, founded the greater number of the Scottish noble families. Malcolm afterwards married Matilda, the eldest sister of Edgar.

William the Conqueror now turned his attention to the north, where his authority had not yet been properly established. From the heart of Mercia to the confines of Scotland a spirit of open insubordination prevailed, and was fostered by Edwin, who had been at one time promised the hand of William's daughter, but was afterwards refused it. The insurrection became formidable; but it was soon quelled, and this served more and more to confirm the power of the Normans. William penetrated as far as York, which opened its gates to him, scattered the isolated and feeble bands who opposed his march, and reduced all the important towns on his way. During this expedition he also fortified a number of castles. The tranquillity thus produced was, however, of short duration. At Durham the English succeeded in massacring the whole Norman force established there, excepting two men. York followed the example of Durham, and rising upon the garrison, killed the governor, with many of his retainers. Shortly after this event, the sons of Harold, the late king, landed from Ireland with the intention of making an effort to recover the crown; but they were utterly defeated in two engagements, by Brian, son of the Earl of Bretagne.

History. 1067.

A new and formidable auxiliary of the malcontents had now however arrived in the Humber; this was a powerful Danish armament. Edgar Atheling, several illustrious Saxons, and crowds of the English, having joined them, they successfully assaulted York; but William, apprised of their descent, hastened to the scene of war. His usual good fortune attended him; and the Danes were compelled to quit the country without crossing arms with the Normans in any conflict worthy the name of a battle. Hints have occasionally been thrown out that they were bribed by the Conqueror; but of this circumstance there is no direct evidence. Upon another point, however, all historians are agreed, namely, that, piqued by these repeated insurrections, the king, in a transport of passion, had sworn to extirpate Northumbria. This merciless vow was performed nearly to the letter. Unbounded license was given to the soldiery, who ravaged the country with fire and sword. The destroying angel could scarcely have left a more desolate wilderness behind. An historian, William of Malmesbury, who wrote sixty years after the event, thus describes it: "From York to Durham not one inhabited village remained; fire, slaughter, and desolation made it a vast desert, which continues to this day." The dead remained unburied; famine, with pestilence in its train, stalked throughout the neighbouring provinces; whilst confiscation brought up the rear of this terrible visitation, and completed the ruin of the country and its inhabitants, gleaning whatever the sword had not destroyed. Such atrocities as these imprint a blot upon the escutcheon of William which it is impossible to obliterate. To his authority the rebel chieftains were compelled to submit; and having thus in the most summary manner crushed rebellion in this quarter of his dominions, he returned southwards, clearing the provinces of the disaffected as he proceeded, and repairing or building castles for the subjection of the country.

William was now undisputed master of England. The conquest of the country, properly speaking, only began

[1] Although not mentioned by our historians, contemporary annalists establish and illustrate the fact that the armies of the continent at this period were in a great measure composed of mercenaries, who followed war as a profession, and hired themselves out to the best paymaster. These individuals were different from those who followed the banners of the barons according to the feudal system. They were little better than hired banditti, and were very numerous in the Low Countries, whence William had sprung. That the force with which he invaded England contained vast numbers of these condottieri, is not only probable, but appears nearly certain, when we contemplate the methods of furnishing out an army in those days. The plunder of the provinces which they overran or conquered seems to have been looked upon by them as not only allowable, but as forming part of their reward. That the affair at William's coronation arose from their rapacity for pillage, which they looked upon as a right, there can be little doubt; and they chose the most fitting time for successfully carrying their project into execution; a time when their leaders were withdrawn, and in attendance at the ceremony going on within the church. They had previously broken out in the same way at Dover.

History. 1067.

with the battle of Hastings. It was not until seven years thereafter, when he carried the terror of his arms to York, that the country was completely subdued. Before that period not one half of England acknowledged his authority. But the spirit of the Saxons was now fairly broken, and finding themselves pursued with such extirpating vengeance, many of them sought refuge amongst the hills and forests, whilst others emigrated to foreign lands. A party of them under Hereward, a resolute chief, attempted to make a stand in the island of Ely, immediately after the northern massacre. This land of fens and marshes was the last asylum of Saxon independence; and Morcar, with some bishops and the remainder of the most conspicuous Saxons, repaired thither. For a while William disdained to notice the efforts of Hereward; but at last he invaded his circumscribed territory, and, scattering his little band, compelled him to fly. This bold and patriotic chieftain afterwards gave in his submission, and being allowed to retain his paternal possessions, the end of his days proved happy. His daring exploits had endeared him to his countrymen, and conferred on him a romantic celebrity. His actions were the theme of many a Saxon song; and even the Normans did homage to his warlike virtues. He was the last of the Saxons who drew the sword in the cause of national independence.

William having now quieted the tumults at home, turned his attention to Malcolm, king of Scotland, whom he compelled to submit. The affairs of the church also occupied him for a time; and several changes were effected, not, it may well be believed, to the advantage of the Saxon prelates. One of them, the Archbishop of Canterbury, was deposed, and his place supplied by Lanfranc, who, although a worthy man, was the creature of William, and in bondage to Rome. In the meanwhile, Edgar Atheling had sought and obtained the friendship of the Conqueror, who, to his honour, ever afterwards maintained this weak and almost imbecile youth in ease and affluence at his court.[1] William now ventured upon another visit to Normandy, where we shall leave him engaged in petty contests, and take a view of the state of England after its subjugation.

By the introduction of a foreign sovereign, a foreign hierarchy, and a foreign nobility, the native population suffered severe depression. To supply the liberal grants of land and places of honour and trust to his followers, the English were of course sacrificed; and thus they were compelled to become the servants or dependents of their conquerors. Contempt and oppression became their heritage. Their farms were pillaged, their females violated, their persons imprisoned, and other indignities heaped upon them, at the caprice of the petty tyrants who were set over them. The principal favourites of the Conqueror had another distinction conferred upon them in addition to the grants of land. This was the earldom or command of the several counties. Two legal revolutions occurred or were completed during the reign of William; the separation of the ecclesiastical from the civil judicature, and the introduction or consummation of the feudal system, for an account of which the reader is referred to the proper head. He effected various other judicial changes which were ultimately beneficial to the community. The crown revenues were a continuation of those which the Anglo-Saxon kings enjoyed; but they appear to have been considerably increased by the various changes which took place, and also very carefully collected; for from an ancient historian we learn that the king's daily income amounted to above one thousand pounds, a sum almost incredible when we reflect that gold was then three times and silver ten times the value which they possess in modern times.

History. 1087.

During the visit of William to his continental possessions, the Norman barons rebelled against him, and were joined by some Saxon chiefs. The king hastened across seas with a band of auxiliaries, and made an easy conquest of the insurgents. The remaining events of his reign are not sufficiently important to require a minute recital. The most remarkable is the revolt of his son Robert, who had been promised the duchy of Normandy when William first invaded England. The French monarch fomented the hostilities between the father and son, which existed for several years, and closed with a most romantic incident. Robert, being besieged in the castle of Gorberoi, engaged a knight enveloped in complete armour, and unhorsed him, at the same time inflicting a wound in his arm. When about to pursue his advantage, Robert recognised in the fallen warrior the voice of his father. A reconciliation was finally effected by the tears and entreaties of Matilda, the mother of this Norman Absalom.

Whilst engaged in a desolating warfare against Philip, king of France, William came before the town of Montes in July 1087, and ordered it to be burned. He rode to view the scene, and galloping among the smouldering ruins, his horse reared and plunged so violently as severely to wound the rider, who was at the time very corpulent and unwieldy. He was carried in a dangerous state to the vicinity of Rouen, where he breathed his last, on the 9th of September. On his death-bed the conscience of the Conqueror appears to have stung him deeply; for he ordered that several prisoners in England, amongst whom was Odo his half-brother, should be set at large; and that restitution should be made for what he had violently destroyed. But these atonements were inadequate to expiate the crimes of which he had been guilty.

The character of William has been drawn in the Saxon chronicle by an Englishman, who was his contemporary, and lived at his court. From this document we learn that the king was very wise, very rich, and "more worshipfull and strong than any of his fore-gangers." It is added, that "he was mild to good men who loved God, and stark beyond all bounds to those who withstaid his will;" and the chronicler goes on to show that he exercised a passionate as well as politic tyranny. That, in fact, he surpassed his contemporary rulers in capacity for command, the events of his life bear ample testimony. All those qualities which fit an individual for directing and controlling the minds of men in troubled times he possessed in an eminent degree. In extenuation of his perfidy and cruelty, it may be urged that these detestable qualities were not more characteristic of him than of the age in which he lived; and that he is conspicuous for them above his competitors only because, from the vigour of his mind, and the great transactions in which he interested himself, he was their superior in every thing else. In a happier state of society, when moral restraint is generally recognised, and influences the development of the mental con-

[1] Sir James Mackintosh, in his *History of England* (vol. i. p. 108), gives a somewhat different account of this youth, but upon what authority is not stated; ours is Mr Turner, who quotes from William of Malmesbury. There is considerable ambiguity in the passage; for Sir James (p. 102 of the same work) says that Malcolm Ceanmore "married the Princess Margaret, after the *death of her brother Edgar*." Now the king of Scotland espoused this princess several years before the events noticed in p. 108, so that one or other of these statements must be erroneous; for none of our historians makes mention of *two* contemporary princes named Edgar belonging to the royal house of Wessex.

stitution of man, his glories would not probably have appeared more stained with blood than those of Cromwell and other warriors who have attained the seat of successful ambition and uneasy power. Neither these palliatives, however, nor his death-bed penitence, can atone for irrevocable crimes, or erase from the page of history such deeds as the Northumbrian massacre.

Much has been written concerning the Norman conquest, for it is a subject of inexhaustible interest. That it became ultimately of incalculable benefit to the country, whatever may have been the suffering immediately consequent upon the event itself, no one can doubt who reflects upon the fluctuating condition of England, its oscillation between foreign bondage and native independence, its internal broils and never-ending distractions, previously to the invasion of the Normans, with the consolidated strength which it internally displayed, and the dignified bearing which it outwardly assumed, after it was conquered by them. Insurrections, though not unknown afterwards, were of less frequent occurrance, and far less alarming, than before; and from the period of the invasion of William, no foreign enemy dared to set his foot upon the soil with impunity. Amongst the financial innovations of his reign was the composition of the Doomsday Book, for an account of which the reader is referred to the article under that head.

The Conqueror left three sons by his wife Matilda. Robert, the eldest, was installed in the duchy of Normandy; whilst William, surnamed Rufus or the Red, from his complexion, obtained the throne of England, and was crowned on the 26th of September 1087. An attempt was made by his half-uncle Odo to dethrone him, and to set up his brother Robert in his stead. But William, alarmed at the formidable demonstrations which were made against him, appealed to the English for aid, and his call was most loyally obeyed. The Normans who had invaded England were compelled to fly, and William carried the war into Normandy, where a reconciliation was effected in the year 1091. The king of England had acquired several continental fortresses, of which he was still to retain possession. It was also stipulated between the brothers, that on the decease of either, the survivor should succeed to the dominions of the other. Henry, the younger brother, who suffered by the treaty, held out several strong places in Normandy; but they joined their forces together, and besieged him in St Michael's Mount, whence he was compelled to fly from want of water.

Robert accompanied his brother to England, where he had been promised possessions as an equivalent for the fortresses which he had yielded up in Normandy. But William did not find it convenient to fulfil the terms of the treaty; upon which his brother, who had again crossed the channel, sent over two heralds for the purpose of declaring him a false and perjured knight. In order to defend his honour, the king followed them into Normandy; but his transactions there belong rather to his own individual history than to that of the country which he governed. The possession of his brother's dominions was a leading object of William's ambition; and he gradually acquired an ascendency in Normandy, which he repeatedly invaded, obtaining new cessions at each adventure. Robert finally mortgaged the whole country to him for three years, at an equivalent of ten thousand merks.

The other events of William's reign were, an invasion of Wales, which was crowned with the usual success; and a war with Scotland, in which the monarch of that country was slain. His government of England was most unpopular. For the gratification of his own appetites, and the enriching of worthless favourites, he plundered the country with impunity. During the life of Lanfranc, his undisciplined rapacity was checked by the wisdom and influence of that excellent prelate. His death, however, removed every restraint, for the king supplied his place by the appointment of an able but remorseless counsellor, who, according to the king himself, was capable of braving the execrations and the vengeance of mankind, in order to gratify his master's desires. Many bishoprics, including amongst these the see of Canterbury, were kept vacant by the king for several years, until a severe illness convinced him of the necessity of appointing a primate. The individual whom he fixed upon was Anselm, one of the most learned and meritorious men of his age. This individual at first demurred to accept the archbishopric, dreading the violence of the king; but the earnest solicitations of his friends at last induced him to comply, and he thus became primate of England. William, as long as his illness was of a dangerous character, showed himself penitent and submissive. He commanded all his prisoners to be released, all his debtors to be forgiven, and all offences to be remitted; and he solemnly vowed that if he recovered he would govern the land in righteousness. But no sooner was he convalescent than he showed that his profession of amendment was only a matter of convenience, and extorted from an unforgiving spirit by the terrors of death. Anselm, as was usual in such cases, brought a voluntary present to his master as an acknowledgment for the dignity which had been conferred upon him; but the gift, not corresponding to the avaricious views of the monarch, was refused, and the unfortunate primate was ever afterwards persecuted by him with the most unrelenting tyranny. Anselm at last sought shelter in Rome, where he continued until William's demise.

The death of the monarch, like his life, was violent. Whilst hunting in the New Forest, he was accidentally struck by an arrow, which buried itself in his breast, and he expired on the spot. The shaft is believed to have been shot at random, and to have come from the bow of Walter Tyrrel, a French knight, who immediately made his escape. This event happened on the 2d of August in the year 1100.

Henry the First, surnamed Beauclerk or the Scholar, ascended the throne of England three days after the death of his brother, the preceding monarch. The compact which had been made between William and Robert was set aside; but the latter, considering himself as aggrieved, invaded England. The formidable demonstrations made by his brother, however, intimidated him, and a pacification was at last effected at the accession of Henry; and the latter propitiated the favour of his subjects by many wise acts. He removed the unpopular agents of his unfortunate brother, particularly Flambard, the obnoxious minister formerly alluded to, and also abolished the oppressive exactions which the latter had enforced. Anselm was recalled, and the clergy conciliated, whilst the people had restored to them the Anglo-Saxon laws and privileges as amended by Henry's father. He also gratified the nation by espousing Matilda, or Maud, daughter of Malcolm, king of Scotland, by Margaret, the sister of Edgar Atheling.

The king now turned his attention to the punishment of the outlaws who had thrown off his authority. Amongst these were included several noblemen, and particularly Robert de Belesme, the most powerful subject in England, and a man haughty, rapacious, and deceitful. He had secured himself within the walls of Shrewsbury, but at the arrival of Henry before this place he made a humiliating surrender, upon which his life was spared, but he was condemned to perpetual exile. Some time after these events Robert unexpectedly arrived in England, where he was received with apparent affection by his brother,

History. 1106. but very soon discovered that he was in reality a captive. The purpose of his visit was to intercede with Henry in favour of the rebels; but instead of compounding for their liberation, he was reduced to solicit his own, which he obtained by consenting to pay an annuity of three thousand merks. After his return to Normandy he entered into terms of friendship with the outlaw Belesme, who possessed numerous castles in the country. Intelligence of this having reached Henry, he renounced the alliance by which he had bound himself to keep the peace with Robert. This compact was similar to that which had subsisted between William and Robert, and a second time the latter became a brother's dupe. Henry invaded Normandy, and a decisive conflict before the walls of Tinchebrai, on the 27th of April 1106, decided the fate of Robert. His army was completely routed, and he himself taken prisoner and sent to England, where he remained in close confinement till his death, which happened in 1135. The cruel fate of this prince has served as a foil to the virtues which he possessed, and shed over them an artificial or spurious lustre. There can be no doubt, however, that his qualities as a warrior were brilliant, and his mind would seem to have been forgiving and conciliatory. Perhaps an amiable weakness in the latter respect was the ultimate cause of his misfortunes. Amongst the prisoners taken at Tinchebrai was Edgar Atheling. Either from his inherent weakness precluding any thing like fear on his account, or from a desire to retain the golden opinions of the Saxons, Henry pardoned him, and from this period the descendant of Alfred intrudes himself no more upon the page of English history.

Robert had a son about five years of age named William, whom a faithful vassal succeeded in conveying to the French court. As the age of this prince advanced, the hopes of his partizans proportionally increased. Henry, after obtaining possession of Normandy, had succeeded in tranquillizing it, and restoring peace and order; but as his nephew grew up, the claims which he possessed to the duchy of his father became more and more popular, and disturbed the quiet both of his uncle and the country. Henry should have at once yielded his paternal inheritance to the young prince; and the withholding of it was an act of injustice which harassed his life and dishonoured his name. The Norman barons, along with the king of France, took part with the injured youth; but this coalition terminated with the battle of Brenville, which was fought in the year 1119. Louis, the French king, had four hundred, and Henry of England five hundred knights. Both princes displayed great bravery during the engagement, which ended, with comparatively but little bloodshed, in favour of the English. William of Normandy made his escape; and the pope, who paid a visit to Henry at Gisors, effected a reconciliation between him and Louis, without touching upon the main cause of quarrel, namely, the difference between the English monarch and his brother Robert, or rather his nephew William, the father being now politically dead.

Matters having been once more pacifically arranged, and the ambition of Henry gratified, he set sail for England towards the end of November 1120. Upon this occasion a most calamitous event occurred in his family, namely, the loss of his only son William. The prince, with a large retinue of gay young knights and noblemen, embarked shortly after his father. Festivity, riot, and intoxication prevailed on board; but in the midst of this feasting and debauchery, the care of the vessel being forgotten altogether, she struck upon a rock near Harfleur, and went down. Of three hundred individuals who were on board, only one escaped to record the dismal fate of his companions. Prince William would have been saved but for the shrieks of his natural sister, which recalled him to the wreck with the boat in which he was proceeding towards shore; and it sunk under the multitudes who crowded into it. History 1135.

This sudden calamity revived the hopes of Henry's nephew William, and disturbed all the arrangements of the king in Normandy. A new war was kindled in that country; but it terminated in 1124 in favour of the English monarch. The discomfited youth, however, received a new favour of fortune. Louis of France bestowed upon him the hand of his sister-in-law; and along with her he received several of the provinces nearest to Paris, which had been united to Normandy by conquest. Soon afterwards he was invested with the earldom of Flanders, which had been left vacant by the assassination of Charles the Good in 1127. In the meanwhile, Henry had endeavoured to perpetuate the succession in his own family, by marrying a second time, after the death of Matilda, his first wife, who had brought him a son and daughter. The premature fate of the former we have already noticed; and the latter, named Matilda, had espoused the Emperor of Germany. The marriage of the king proved to be without issue; and his daughter having recently become a widow, was invited to England, for the purpose of settling upon her the succession to the throne. In a general assembly of the prelates and chief tenants of the crown she was proposed by her father and acknowledged by the meeting as heiress presumptive; and shortly after this transaction her father privately married her to the Count of Anjou. This secret negociation drew forth loud complaints from the barons; and many of them declared that the duplicity of the king had released them from the obligation of their oath. This doubtless disturbed the serenity of the king's reign; but another and more important cause of disquietude arose from the increasing power and fame of his nephew in Flanders. However, the death of that prince soon afterwards removed all uneasiness on his account, and restored at least the prospect of tranquillity. But this was not realized; for a quarrel with his son-in-law retained him in Normandy, and embroiled the last years of his reign, which was now drawing towards a close. Robert, the unfortunate duke of Normandy, died at Cardiff Castle in Wales, in the eightieth year of his age and twenty-eighth of his captivity, a great part of which had been spent in total blindness; for an unsuccessful attempt to escape had provoked his brother to deprive him of sight. All the historians of the period do not mention this circumstance, and some state that the prisoner enjoyed every indulgence; so that the point is doubtful, and for the honour of humanity we leave it in this state. In about a year thereafter, he was followed to the grave by king Henry, who died of a surfeit of lampreys, on the 1st of December 1135, in the sixty-seventh year of his age and thirty-fifth of his reign.

The character of Henry has been drawn by both friends and enemies, his contemporaries. The former extol him as wise, rich, and brave; and the latter execrate him as cruel, avaricious, and incontinent. By joining the two characters together, we will form a pretty fair estimate of the monarch. He was undoubtedly an able statesman and a courageous soldier, whilst his resolute attack upon the popular system of rapine which disgraced Europe at the time is entitled to very high praise. He punished offences severely; but his administration of justice was highly beneficial to the country; and hence arose his title of the Lion of Justice. On the other hand, the immorality of his private life, his exactions, his cruelty to his brother and others; his dissimulation, for even his favourites distrusted him; and his avarice, for he hoarded gold like a miser; render his character exceedingly equi-

History. 1135.

vocal as a man, whatever estimate we may form of him as a sovereign. His reign offers little worthy of praise, excepting what has been noticed above. It was moreover so agitated, that he passed only five years of untroubled tranquillity in England.

It was the darling plan of Henry that his beloved daughter Maud should be his successor. By her second husband she had three sons, one or other of whom their uncle no doubt looked upon as the future monarch of England. But the claims of the ex-empress of Germany were waived, and Stephen earl of Boulogne, son of Adela, the daughter of William the Conqueror, succeeded to the throne. He was crowned upon the 26th of December 1135, and soon made himself very popular. According to custom, he immediately issued a charter, which promised of course good government and ample redress of grievances. His courts at the solemn festivals were held with extraordinary magnificence. He repulsed the invasion of David king of Scotland, who received a severe defeat at the Battle of the Standard, which was fought near Northallerton; he subdued his enemies in Normandy; and, by a yearly pension, he pacified the husband of the lady whom he had supplanted upon the throne. Robert earl of Gloucester, natural son of Henry, and the great supporter of Maud's rights, perceiving all hostility to be unavailing, at last swore fealty to the king. For the first two or three years of his reign, Stephen sat secure upon the throne; but he was doomed to be overtaken by a series of calamities. These arose partly from the inevitable consequences ot his usurpation, and partly from his defects as a sovereign. That passion for depredation and conflict which the preceding monarch had subdued, again broke out. Every one built his own castle and maintained his own band of mercenary ruffians, who sallied forth day and night to plunder the surrounding country, and drag into dungeons such as they expected would give a high ransom for their freedom. A contemporary chronicler has drawn a horrible picture of the atrocities thus committed with impunity; for the mildness of Stephen's character, and probably the recollection of his own conduct in obtaining the crown, induced him to be forbearing and indulgent. His popularity rapidly declined; and in the fourth year of his reign it appears to have altogether ceased. In 1139 Matilda, with a few attendants, landed in England, for the purpose of recovering her lost inheritance. She was joined by Robert earl of Gloucester, with a hundred and fifty knights, who commenced a warfare which nearly hurled Stephen from the throne. After many conflicts, which were only characterized by the misery attendant upon them, the army of the Empress Matilda or Maud defeated that of Stephen near Lincoln, in the year 1141. The king was captured after a brave resistance; and Matilda was soon afterwards crowned queen of England at Winchester. The clergy, although they countenanced the accession of Stephen, now acknowledged her prior claim; and the queen, proceeding to London, was joyfully hailed by the citizens.

But her popularity was of short duration. By her arrogance and contemptuous conduct towards the friends of Stephen, she soon alienated the affections of the people, and was at last compelled to fly from the city and to establish her head-quarters at Oxford. In one of the numerous struggles which followed, the Earl of Gloucester was taken prisoner, which put the fortunes of the belligerents nearly upon a level. The king and the earl were exchanged for each other; and as both parties had now a commander upon whom they could depend, the conflict was perpetuated, with increasing misery to the nation. For some years the balance of power hung nearly in equipoise between them. Stephen reduced Oxford, but Robert defeated him at Wilton; and this miserable warfare continued, until, on the death of her brother Robert, Matilda returned to Normandy in 1147, when a breathing time of two years intervened.

History. 1154.

In the meanwhile Henry, the son of Matilda, was advancing in years and in fortune. By his uncle David, king of Scotland, he had been knighted at the age of sixteen; a year thereafter he obtained from his father the cession of the duchy of Normandy; and at the death of that prince he succeeded to the earldom of Anjou. In 1152, by a politic marriage, he annexed the extensive duchy of Aquitaine to his dominions. This aggrandizement of her son's power having elevated the hopes of Matilda and those of her partizans, Prince Henry landed in England; but in consequence of the death of Eustace, the oldest son of Stephen, the two parties agreed to terms of peace. Stephen adopted Henry, and appointed him as his successor, one of the best acts of his troubled reign. They lived in harmony with each other for about a year, when Stephen died on the 25th of October 1154. He reigned nineteen years, during the greater part of which time England exhibited a scene of misery unequalled since the invasion of the Danes. The cause of these calamities we have already alluded to. The character of Stephen is not so deeply stained with atrocities as that of some of his predecessors, probably because it was not so determined. In comparison with them, the grasp which he held of the sceptre was as feeble as his right to seize it at all was equivocal.

Henry II. or Plantagenet, the son of Matilda, ascended the throne without a dissenting murmur. He was crowned, along with his queen Eleanor, at Westminster, on the 19th of December 1154, in presence of an immense concourse of people. The prospect which opened up to this young sovereign was more glorious than that of any of his forerunners in England, or his contemporaries in other countries. An unprecedented mass of power was concentrated in his hands. A third part of France, including almost the whole western coast from the borders of Picardy to the mountains of Navarre, acknowledged his authority. These possessions, along with England, comprehended the most warlike portion of Europe; and had the ambition of the individual who ruled over them been commensurate with his power, the humiliation, if not entire subjugation, of France would not have been reserved for the Henries and Edwards of after times. Although by no means destitute of a passion for power, Henry possessed a love of literature, which led him to eschew the cloudy and troubled atmosphere of war. The civil discord which prevailed during the reign of his predecessor had inflicted numerous evils on the nation, and to the alleviation of these Henry devoted the first years of his reign. He issued a new coinage, of standard weight and purity; he drove beyond seas the foreign mercenaries who had harboured in England during the reign of Stephen; he seized the royal castles which had been usurped, and demolished those which had been reared for the purpose of systematic plunder. By these vigorous steps of reformation Henry secured the effective administration of justice in his English dominions. One of the leading features of his character was restless activity. On foot or on horseback he was perpetually in motion; and the moments which he could spare from more important concerns were usually devoted to the chase.

Some of the leading events of Henry's reign are associated with the name of Thomas a Becket, who has been portrayed as a saint and martyr, or a hypocrite and traitor, according to the religious bias of the historian who happened to draw the picture. Under the article Becket an account of this celebrated prelate will be found; and it is only necessary in this place to allude to those events of his life which are identified with the history of his

History. 1161. country. One of Henry's first measures was the promotion of this individual to the chancellorship of England, in which capacity he vigorously seconded the measures of reform which the king had undertaken. His administration has been characterized as alike beneficial to the country and to the sovereign, who loaded his favourite minister with honours and emoluments. By the advice of Becket, Henry proposed a treaty of marriage between his eldest son and the daughter of Louis king of France. On this occasion the chancellor undertook a journey to Paris, displaying upon the occasion a pomp and parade transcendently elaborate. Henry himself followed; and although a rupture ensued between the sovereigns about the city of Toulouse, which belonged of right to the king of England, their enmities terminated with the marriage of their children whilst the infants were as yet in the cradle. We have now arrived at that period of Becket's life in which his conduct has been the subject of a kind of historical crusade. In 1161 Theobald the archbishop of Canterbury died, and Becket was recommended as his successor by the king. The clergy of England, however, resisted the nomination, declaring it to be unseemly for a man who was rather a soldier than a priest, and whose life had been devoted to hunting and falconry, to be appointed an archbishop. More than twelve months elapsed between the nomination and appointment, during which time Becket still retained the chancellorship, and evinced no change in his feelings or way of living, which was eminently worldly. He even went so far as to smile at the idea of metamorphosing the gay and pompous Chancellor of England into the Archbishop of Canterbury; and he appears himself to have thought that the choice arose from Henry's confidence that he would become the pliable instrument of his will in ecclesiastical affairs. If the king anticipated such a consummation, never were the hopes of man more miserably disappointed. For no sooner was Becket invested with the primacy, than a change took place in his manners, more strongly contrasted with his former life than were the two offices which he had held. Instead of a train, which in splendour and fastidious pomp had rivalled the retinue of kings, he chose a few monks the most conspicuous for their humility and mortification. Instead of the oriental magnificence and gorgeousness of apparel with which he loved to dazzle the eyes even of courtiers, he selected as his chosen garment the roughest sackcloth. His sports and revels were exchanged for deeds of penitence and humiliation. And thus far his conduct appears to have been commendable; but did his future behaviour warrant a belief that this sudden change was attributable to the sincere conviction of a pure and lofty spirit, which had changed its views regarding the relative value of earthly and heavenly things, or to the policy of a deep and designing hypocrite? The remaining particulars of his life will best enable the reader to form his own judgment as to this, which is one of the most disputed points in our history.

The first step which Becket took after his promotion was to return the seals of his former office to Henry, on the ground of his incompetency to hold two such offices. This measure is said to have at first excited the indignation of the king, who had never before heard Becket object to the prelacy on that account. But it was not until 1163, when hostilities commenced between the church and the state, that Becket and the king came fairly into collision. Previously to the Norman conquest, ecclesiastical affairs had, like others, been decided before the hundred, with the addition of the metropolitan sitting as one of the judges. The Conqueror, however, had instituted a separate tribunal, where the clergy were judged by a court composed of themselves, and from that time they were independent of secular jurisdiction. Becket upheld this claim with firmness, as he ought to have done, until it was formally set aside by the king and his counsellors. This, however, did not justify the decisions which were pronounced, and which had now become notoriously partial. Crimes of the darkest description had frequently been perpetrated by ecclesiastics with the most scandalous impunity; for the judges could not inflict capital, nor indeed any adequate punishment. An abominable instance of seduction having attracted the notice of the king, he determined that those chargeable with such atrocities should be tried before the criminal tribunals of the state. For this purpose he summoned a great council at Westminster, where he demanded that ecclesiastics, whenever convicted of such offences, should be degraded, and handed over to a secular justiciary. His question was, Would they agree to observe the ancient customs of the realm? Becket answered yes, saving his order; an ambiguous reply, which was echoed by the conclave of bishops present, with only one exception. But, although not at this assembly, he was afterwards compelled to yield the point without any reservation respecting his order. This formal assent was obtained at the celebrated council of Clarendon, which took place on the 25th of January 1164. At this great or common council of the realm, for the word parliament had not yet been introduced, Becket was compelled to yield compliance to the demands of his sovereign. At first he peremptorily refused his acquiescence; but the king, incensed at his obstinacy, menaced him with exile or death, whilst several individuals of rank present entreated him with genuflections and tears to submit; by which means a compliance was at last reluctantly wrung from him. These customs and usages, the recognition of which was thus so vehemently urged, were contained in sixteen articles, which were afterwards well known under the name of the Institutions of Clarendon, by which it was enacted that clergymen accused of any crime should be tried in civil courts; that laymen should not be tried in spiritual courts, except by legal and reputable witnesses; that no ecclesiastical person should quit the realm without the king's license; that all causes not ecclesiastical should be finally determined in the king's court; that all ecclesiastical persons who were tenants *in capite* of the crown should follow the king's customs, sue and be sued respecting their fiefs before his justices, and attend, like other barons, at his courts; that vacant dignities in the church should be in the king's hands; and that he should also receive the profits of his seignorial dues. These, with some others, to the number of sixteen, were subscribed by all the ecclesiastics present, including Becket himself. He was now not only mortified in the highest degree, but, pretending extreme contrition for what he had done, did open penance for his supposed delinquency. He attempted to make his escape to France, but was arrested for an offence against the institutions which he had recently signed. Henry was now exasperated beyond all bounds at the archbishop, and assembled a parliament at Northampton, obviously for the purpose of crushing him. Becket was accordingly summoned to account for rents and profits connected with his primacy. He arrayed himself in his sacerdotal vestments, and, with the cross in his hand, proceeded to the place appointed. The king complained to the council of the insolent behaviour of Becket, and the whole assembly joined in condemning his inconsistency. The suit regarding rents, which was only intended as a menace, he attempted to free himself from, by pleading a release by Henry the king's son; but this was overruled. After being condemned as a perjured traitor he left the palace, his eyes fixed upon the cross, which he held uplifted in his hands; and, travelling in disguise, he

History. 1164.

History. 1164. reached the port of Sandwich, whence he immediately embarked for the Continent.

Becket was received with marks of esteem by the king of France, and likewise by the pope, whose cause he had so strenuously defended in England. When Henry learned the flattering reception which the obnoxious exile had received, he dispatched an embassy to expostulate with Louis, and sent another to Rome, to justify his conduct to the pontiff. But the ambassadors were received with coolness, if not with something which bordered upon contempt. The judgment of the barons and bishops was annulled by the pope, and those who should invade the property of the church were declared to be cut off from the society of the faithful. Henry's irritation had now reached its climax, and he resolved upon taking a bold step, which, had the human mind been ripe for such a measure, might have ended in the separation of the English church from that of Rome; but this achievement was reserved for the Henry of a future day. He gave orders to his justiciaries, prohibiting, under severe penalties, all appeals to the pope or the archbishop, and forbidding any person to receive mandates from them, or to apply to their authority; and he declared it treasonable to bring over from either any interdict against the kingdom. On the other hand, the pope was not slow in issuing his fulminations. Becket was ordered to excommunicate Henry's chief ministers, and put the see of Canterbury, including about three fourths of the kingdom, under an interdict. But Henry stood firm, and looked with indifference upon the papal lightnings which played around him. At last, however, he began to dread the powers of his victim, chiefly on account of his continental dominions, and proposed a reconciliation. The treaty of accommodation, although more than once broken off, was finally concluded, and Becket returned to the see of Canterbury without having been compelled to make any express submission to the institutions of Clarendon.

But the wounds had been too deep to be thus suddenly healed, and, though closed at the surface, the venom still rankled underneath. The arrogance and presumption of the primate returned along with his dignity. He refused compliance with the terms of the general amnesty, and would not submit to take the oath of homage for his baronry; neither would he withdraw the whole of the ecclesiastical censure from the prelates who lay under it on account of their obedience to the king's commands. Several very imprudent excommunications soon followed, and so provoked Henry that he is said to have dropped certain passionate expressions, intimating something which was interpreted into a desire that Becket's life might be taken away. The supposed will of the king was instantly accomplished by four knights of distinguished rank, who repaired to the church of Canterbury, where the primate then officiated, and barbarously slew him at the foot of the altar. See Becket.

Thus perished by foul murder, in the fifty-third year of his age, Thomas a Becket, who, every thing considered, was probably the most remarkable man of his time. That he believed he was all the while conscientiously performing his duty, in preserving the immunities of the church, there seems little reason to doubt; for he would not have met his fate with such heroic and martyr-like firmness unless this had been the case. His virtues were of an austere character, and wanted that amiable attractiveness which we usually associate with the character of one who is profoundly inspired by the morality of the gospel. His vices, on the other hand, were the reverse of mean and grovelling; for his spirit was lofty and aspiring, and his designs were invested with a dazzling grandeur, and pursued with a fearless firmness much more calculated to excite awe than detestation, far less contempt. That Henry did not intend the murder of Becket, appears certain from his subsequent conduct. He was thrown into the utmost consternation on hearing of it, knowing well that the primate's death would accomplish what his most violent opposition during his lifetime could never have effected. He abandoned himself to sorrow and mortification, and for some time refused to take any nourishment. The pope was with some difficulty made sensible of the king's innocence; but declined to grant him a pardon, except on condition that he should make every future submission, and perform every injunction which the holy see thought proper to prescribe or impose. He was likewise enjoined to perform a humiliating penance at the tomb of Becket, who was in due time canonized as a saint and venerated as a martyr. The assassins, despairing of pardon, sought refuge in a distant castle. By the pope they were enjoined to make a pilgrimage to the Holy Land, where they all died, and were buried before the gate of the temple at Jerusalem.

History. 1172.

We come now to a very important event in the reign of Henry II. that is, the annexation of Ireland to the English crown; but the details of his invasion it is unnecessary to relate here, as they will come in due order to be treated of under the head Ireland.

The king was scarcely freed from the Irish war, and the dangerous controversy in which he had engaged with the church of Rome, when he found himself involved in the most unnatural contests with his own children, to whom he had always behaved in the most tender and affectionate manner. He had ordered Henry, his eldest son, to be anointed king; and he had destined that prince as his successor in the kingdom of England, the duchy of Normandy, and the counties of Anjou, Maine, and Touraine, territories which lay contiguous, and which might thus easily afford mutual assistance to each other when necessity required. Richard, his second son, was invested with the duchy of Guienne and the county of Poitou; Geoffrey, his third son, inherited, in right of his wife, the duchy of Brittany; and the new conquest of Ireland was destined for John, his fourth and youngest son. The last sixteen years of Henry's life were embittered by family hostilities. A mighty confederacy was secretly formed against him, in which his three eldest sons participated. Louis VII. king of France, fed the discord; for the power of the English monarch had now become so formidable as to excite alarm and kindle up jealousy in the breasts of the continental sovereigns. The young prince was persuaded to demand of his father some of the dominions which he had been promised, and of which he was nominal sovereign; but he was refused. Upon this the prince made his escape, and put himself under the protection of the king of France. The French monarch then invaded Normandy; and Richard and Geoffrey, the sons of King Henry, severally raised the standard of revolt in Guienne and Bretagne. William the Lion, king of Scotland, considering this as a favourable opportunity for invading England, advanced into the northern counties, destroying all he met with. A great force of foreign mercenaries, called Brabançons, landed in Sussex, under the command of the Earl of Leicester, whilst Prince Henry collected another army in France in order to co-operate with them. To meet this formidable coalition against his authority, King Henry made the best preparations which circumstances admitted of; and if we may judge of these by the results which followed, he must have taxed his constitutional activity to the utmost in collecting forces, and in opposing a barrier to the tide of war which thus rolled onward from every quarter, threatening to overwhelm his throne. Few of his own barons could be depended upon, and he had

History. 1174. recourse to the foreign mercenaries so largely employed by his adversaries. Twenty thousand of these auxiliaries enlisted under his banners, and with them were united such of his own nobles and retainers as could be trusted.

The enmity of the young princes against their father had been in no inconsiderable degree excited and fostered by Eleanor their mother, whom the incontinent and licentious life of Henry had for ever estranged from her affections. She attempted to make her escape; but was taken prisoner, and consigned to close imprisonment, where, with the exception of a short interval, she remained till the death of her husband.

In the meanwhile, the plan devised by the allies began to be acted upon, as already indicated; but Henry of England proved himself superior to the emergency. His foreign enemies were on all sides discomfited, and William of Scotland having accidentally fallen into the hands of Henry, the Scottish army broke up and dispersed. Their sovereign afterwards obtained his freedom by the humiliating surrender of his authority as king of Scotland; for conceding to Henry the title of lord paramount of his kingdom was virtually casting his crown at the feet of his enemy. A pacification was brought about at Falaise, on the 28th of September 1174, by which the princes were pardoned and enriched with new liberalities.

King Henry, however, was permitted to enjoy but a few years of repose. The dissensions between him and his children again broke out. The latter also quarrelled amongst themselves, and a most unnatural war ensued, in which neither party gave quarter. But the death of Henry, the eldest son, for a time suspended these disputes. This unfortunate prince died in 1183, of a fever brought on by vexation and fatigue. Three years afterwards Geoffrey perished beneath the feet of a horse in a tournament at Paris, so that the subjects of discord were diminished. The widow of Geoffrey, soon after his decease, was delivered of a son, who was named Arthur, and invested with the duchy of Brittany, under the guardianship of his grandfather, who, as duke of Normandy, was also suzerain lord of that territory. Philip, as lord paramount, disputed the title of the English king to this wardship; but he was obliged to yield to the wishes of the Bretons, who preferred the government of Henry. Some other causes inflamed the dissension between these monarchs, and Philip once more seduced Richard from his duty. He insisted that the marriage of that prince with Adelais, his sister, should be immediately completed, and threatened to enforce his demands with a formidable army. This lady had been confined for a long time in a castle by Henry, who procrastinated the nuptials, until a suspicion arose that he intended to appropriate her to himself. At the conclusion of the truce which had followed the death of Geoffrey, Richard finally forsook his father, and did homage to the king of France for his continental dominions.

For some time the eyes of the monarchs of Christendom had been turned to Palestine, which the Sultan Saladin was overrunning with his mighty hosts. Henry of England was desirous of taking the cross and proceeding to Syria, but his perpetual contests with his family detained him until the holy city was taken by the infidels. The news of this event awakened feelings of regret and indignation throughout Christendom. The Emperor of Germany marched his bravest knights towards Asia. Philip of France and Henry agreed to follow, but the union of the former with Richard the son of the latter compelled the king of England, in the first place, to look to the defence of his own territories, which were once more invaded by the confederates. The war proved very unfortunate for Henry, who lost several towns, and very narrowly escaped falling into the hands of the enemy. A treaty was at length agreed to, but the terms of it were very humiliating to the English monarch. With a heart overwhelmed with grief, he returned to the castle of Chinon, where he soon afterwards expired, on the 6th of July 1189, in the thirty-fifth year of his reign and the fifty-seventh of his age. Upon his death-bed he was sedulously attended by one of his natural sons, the fruit of an amour with Rosamond, whom popular romance and tradition have surnamed the Fair, and invested with every virtue but one. Henry was interred with little pomp in the convent of Fontevraud, in the presence of his rebellious son Richard, and a few knights; but Eleanor, his queen, survived him many years, having been liberated by her son Richard. The character of Henry II. has been already detailed at sufficient length. During his reign important changes in ancient law and usage were matured, and became conspicuous, on which account they have been ascribed to the administration of this monarch; but it is more probable that they resulted from the slow growth of circumstances, with little aid from rulers, who were perhaps unconscious that any change had occurred.[1] History. 1189.

Richard I. succeeded to the throne without opposition, and was crowned on the 3d of September 1189. The reign of this monarch, the Achilles of modern Europe, is interwoven with events which are more akin to romance than to real history. His life is made up of the adventures of a knight-errant. His character was a singular compound of qualities noble and mean; of the grand and the grovelling, the sublime and the grotesque. It has been thus drawn by Mr Turner, in his *History of England:* "Haughty, irascible, and vindictive, a towering and barbaric grandeur, verging sometimes into barbarian cruelty, distinguished his actions. Valiant beyond the common measure of human daring, unparalleled in his feats of prowess; inferior to no man in hardihood, strength, and agility; stern and inflexible in his temper; rapacious and selfish, yet frequently liberal to profusion; gorgeous to ostentation, yet often gay, familiar, satirical, and jocular; unshaken by adversity; resolute to obstinacy, furious in warfare, fond of battle, and always irresistibly victorious; his life seems rather the fiction of a poet's imagination than the sober portrait of authentic history." But this character for martial prowess and heroism was softened by a love of literature, particularly Provençal poetry; and although the specimens of his compositions which have been transmitted to us scarcely deserve the name of poetry, still they evince the presence of the passion in his mind. It was the same sentiment which thus penetrated the tempestuous atmosphere so congenial to his soul that imbued his exploits with the spirit of genius and romance. An overweening love of praise added its inspiration to his feelings, and contributed to render his actions pre-eminently conspicuous even in the high and palmy age of chivalry. He had no sooner ascended the throne than he began to make arrangements for joining the new levies of crusaders preparing to embark for the Holy Land. In such a sphere nature had fitted the king of England to shine without a rival. His landing in Palestine was destined to mark an era, when the Moslemins were to encounter a warrior superior even to the most distinguished of their own in lofty daring and proud contempt of danger, and when the brows of their bravest chieftains were to darken at the name of Richard.

[1] Mackintosh's *History of England*, vol. i. p. 172.

History. 1189. At his coronation an event occurred which it is painful to mention, and too shocking to give in detail. The Jews, eager to express their fealty to the new sovereign, approached him in numbers, bearing rich presents of gold and silver, commodities which they well knew would be peculiarly acceptable to the king. In their endeavours to press forward towards the hall door during the state dinner, a scuffle ensued. The Jews resisted the ill treatment they received, which so inflamed the passions of the English mob that they arose upon the defenceless strangers, and drove away or destroyed them. This example of violence spread not only over the city, but throughout the country; and the unfortunate Israelites were massacred and plundered without mercy. It was in vain that the king attempted to allay the tumult; the sanguinary rabble would not desist until its ferocity and rapacity were completely satiated.

Richard having equipped his armament, and acquired the necessary treasure by every means in his power (and from his natural impatience he was never scrupulous upon that point), joined Philip of France and marched with him to Lyons. As the principal events connected with this expedition are already embodied in the article CRUSADES, we shall not recapitulate here the whole details, but only notice such as have not been there introduced. On his way Richard relieved Portugal, by joining the sovereign of that country with five hundred knights, and bidding defiance to the Moors or Saracens. This was an evil omen for the followers of the Prophet. After landing at Messina, he remained there six months, which were chiefly occupied in warm disputes with Tancred, who had usurped the Sicilian crown. On the 10th of April 1191 Richard set sail from this place; but his fleet having been dispersed by a storm, and the ship in which were his sister Joan, and his betrothed wife Berengaria, being driven into Cyprus, he landed on that island for the purpose of chastising the governor, who had treated the royal ladies with some discourtesy. Richard reduced the whole island, and after marrying Berengaria, and causing her to be crowned queen of England, he set sail for St Jean d'Acre, which afterwards surrendered to him. (See ACRE.) The fall of this place opened the way to Jerusalem, towards which he now advanced, performing on his way those chivalrous deeds which taught the infidels to shudder at the apparition of his name. (See CRUSADES.) In October 1192 Richard set sail from the Holy Land for England, with a fleet, which contained his wife and sister, who appear to have reached their destination in safety. But a storm having dispersed the ships, Richard was driven near Marseilles. Having learned, however, that plans were in agitation to seize his person (for Philip of France and other continental sovereigns, together with his brother, were leagued against him), he formed the unfortunate resolution of passing through Germany in disguise.

He landed at Zara, and after a variety of adventures and hairbreadth escapes, he was at last arrested by Leopold, duke of Austria, who immediately ordered him to be loaded with fetters. This prince had served under Richard at the siege of Acre, where he received, or imagined he had received, some injury at his hands, and took this base method of revenging himself. Henry VI. emperor of Germany, was then equally an enemy to Richard, on account of his having married Berengaria, the daughter of Tancred king of Sicily. He therefore required the royal captive to be delivered into his hands, and stipulated to pay a large sum of money to the duke as a reward for his services. History. 1199.

The disaster which had befallen the English monarch could not be long concealed. The news of his captivity spread general indignation at home; a feeling which was responded to by the disinterested portion of Europe. Richard's mother, along with the clergy of Germany, appealed to the pope; and the emperor, finding that his conduct was condemned as disgraceful, made an attempt to justify it, by charging his prisoner with several weighty crimes. These were, his behaviour in Sicily, his conquest of Cyprus, and the alleged murder of Conrad, who was assassinated whilst contending for the Christian kingdom of Palestine. The latter charge being by far the most serious, every effort was made to vindicate Richard from the guilt of the alleged crime. At home the ministry exerted themselves to the utmost; and the most able prelates set out for the Continent to bargain for his ransom. He was removed from a dungeon in the Tyrol to the residence of the emperor at Haguenau, and was taken from thence to Worms, for a final adjustment of differences.

In the meanwhile, his brother John, with Philip of France, were busily prosecuting their plans for his destruction. Their design was to effect the utter ruin of Richard; and every method was tried to accomplish their purpose. John made his feudal submission to Philip for his brother's continental possessions; and having assembled an army, he returned to England with the intention of seizing the crown, whilst his colleague invaded Normandy. Both the confederates were completely unsuccessful. John, by circulating false reports of his brother's death, attempted to give a gloss of right to his projected usurpation; but his duplicity was too well known, and his armament of foreign mercenaries was repulsed from the coast.

The negociations for Richard's liberation ended at last in the agreement that a ransom of one hundred thousand marks of silver should be paid for it. It was in vain that his mortal enemies, Philip and John, protracted his imprisonment. By a general tax the sum was raised; and soon after his emancipation he set out for England, where he arrived on the 13th of March 1194. The remainder of his reign is very unimportant; it was chiefly occupied with a species of petty bickerings with Philip of France. The money required for the crusade, and the ransom of Richard, had so exhausted the finances of England, that the king found himself unable to undertake war upon a grand scale. If we contemplate the character of the individual who found himself thus fettered by pecuniary necessities, this was a fortunate circumstance. It would be difficult to estimate the amount of human misery which was thus saved. After various undecisive battles and equivocal victories, Richard was mortally wounded before Chaluze, an obscure castle in the province of Limousin, held by a rebellious vassal, and expired on the 6th of April 1199, in the forty-second year of his age and the tenth of his reign.

Thus perished, in the prime of life, one of the most romantic characters to be met with in real history.[1] His character we have already given; and with respect to his reign, we cannot discover anything in which it added to the civilization or prosperity of the country. For the immense sums of money which he drew from it, the only

[1] The lines which Dr Johnson applies to Charles XII. of Sweden are literally true of Richard Cœur-de-Lion of England

His fate was destined to a foreign strand,
A petty fortress, and a dubious hand;—
He left a name at which the world grows pale,
To point a moral or adorn a tale.

History. 1199. return worthy of notice was an equalization of weights and measures throughout the realm.

John, the brother of the late king, and the youngest legitimate son of Henry II., succeeded to the throne without opposition; for, although the hereditary right, according to the modern acceptation of the term, was vested in his nephew Arthur, son of John's elder brother Geoffrey, the uncle had likewise a hereditary claim, as being nearest of kin to the deceased monarch, and the nation declared in his favour. His coronation took place on the 27th of May 1199. The character of John is perhaps more strongly marked, and possesses more individuality, than that of any other monarch on the list of English kings. In cowardly villany, in perfidious malignity, in base ingratitude, in unprincipled cruelty, in grossness of appetite, in meanness, weakness, and every vicious infirmity, this prince figures in the page of history almost without a rival. Other kings there may have been whose vices are black enough to call forth the execrations of posterity; but the halo of talent which emblazons their names serves to mitigate the severity of censure. John, however, stands before us utterly divested of any such quality; his character is unredeemed by one solitary virtue; his reign is unillustrated by one solitary good action performed without compulsion. He is altogether alone, the lowest and most abject slave that ever wore a crown.

Richard had destined Arthur as his successor, and, on his death, Mons, Tours, and Anjou, appointed the youth, then Earl of Bretagne, their lord. On the assumption of the crown of England and the dukedom of Normandy by John, Constance, the mother of Arthur, gave her son over to the care of Philip, king of France, who claimed for him his continental possessions. A struggle ensued between the monarchs of France and England. Philip, who, it would appear, used Arthur entirely as a tool to suit his own purposes, sent him with a military retinue into the dominions to which he laid claim. He took the town of Mirabeau, saving a tower, which held out under Eleanor, the widow of Henry II.; but on the night between the 31st of July and 1st of August 1202, John arrived, and compelled the besiegers to surrender. The prisoners were treated with a cruelty truly demoniacal, and worthy of the man; but this was only the opening scene of the tragedy. Prince Arthur was brought to Falaise, where he was confined for some time. He then all of a sudden disappeared, and contemporary history has ascribed to John the guilt of his murder. That the hapless youth met with a violent death is evident, and that he fell either by his uncle's own hands, or by his orders, there seems no reason to doubt. Even in that semi-barbarous age, there was scarcely an individual capable of committing such an atrocity, excepting the wretch who, a few years afterwards, took a diabolical pleasure in starving to death the wife and children of a nobleman who had offended him, and hanging twenty-eight Welsh hostages, besides other atrocities too horrible to be named.

By this foul deed, a third part of John's dominions were wrenched from his grasp. Philip Augustus summoned John, as duke of Normandy and Aquitaine, to answer before a court of peers to the charge of having murdered Arthur duke of Brittany. But he dreaded the tribunal, and having refused to appear, he was branded as a murderer, condemned to death, and adjudged to lose all his French territories. The king of France moved onwards from conquest to conquest, and one by one the provinces of the English monarch were seized and annexed to the dominions of Philip; Touraine, Maine, and Anjou in 1203, the duchy of Normandy in 1205, and the county of Poitou in 1206.

Another important event in the reign of John was his contest with the pope, the only contest indeed in which he ever displayed any thing of that spirit which had fired the bosoms of his ancestors. The clergy had for some time acted as a community independent of the civil power, owning subjection to the pope alone, by whom their elections were usually confirmed. The election of the Archbishop of Canterbury had been a subject of contention between the suffragan bishops of the province, and the monks of St Augustin's Abbey in that city. Each party claimed the right of choosing; but under this question was concealed the more important one, whether the king or the pope had the power of nomination; for the bishops were accessible to the influence of the crown, and the monks, in consistency with the genius of their order, were biassed by Rome. In the mean time the archbishop died, and the monks privately elected Reginald their superior in his room. The bishops remonstrated against this as an innovation on their privileges; and the king took part in the contest, with the resolution of raising the Bishop of Norwich to the primacy. The cause was appealed to Rome; and Pope Innocent III., eager to extend his power in England, commanded the election of Stephen Langton, a most unexceptionable individual, and one who, in the sequel, proved himself eminently worthy of the highest station. John, however, incensed at this proceeding, violently expelled the monks from their convent, took possession of it himself, and seized upon the revenues. The tiara, however, was not to be thus contemptuously treated. An interdict was threatened, unless compliance with the wishes of the papal court was immediately yielded. In vain the prelates in the most supplicating manner entreated the king to give his consent to the measure. With that stoical indifference to human suffering which he uniformly evinced, he determined that both himself and the nation should brave the vengeance of Rome. He swore that if it descended upon him, he would banish the whole clergy, and confiscate their possessions. The pope, however, laughed his menaces to scorn, and published that terrible interdict, which in those ages was calculated to make the heart of a nation tremble. A stop was immediately put to divine service, and the administration of all the rites of religion except baptism, and the confession, absolution, and extreme unction to the dying. The church-doors were shut, and the images of the saints deposed. The dead were refused Christian burial, and thrown promiscuously into ditches and on the highways, without any funeral solemnity. Other injunctions, equally severe, were included in this formidable interdict; and John, in revenge, persecuted the clergy with unsparing rigour. But his furious and imprudent efforts proved useless. Innocent remained firm, and, in two years thereafter, 1209, launched his last thunderbolt at the English monarch. He excommunicated John, absolved his subjects from their oath of allegiance, and soon afterwards deposed him. He also commissioned the king of France to take his crown; and published a crusade all over Christendom against King John, exhorting the chivalry of Europe to take up arms against him, and enlist under the French banner. Philip was not less active on his part. He summoned all the vassals of the crown to attend him at Rouen; and having collected a fleet of 1700 vessels, was ready in 1213 to invade England.

History. 1213.

But the fulminations of the pope were alike disregarded by John and his subjects, who had now become familiar with them. His strength does not appear to have been lessened, for the only successful expeditions of his reign, those against Ireland and Wales, were undertaken during the period of his proscription by the see of Rome. In order to meet the king of France, he assembled a vast army; but it was not the interest of his holiness to allow matters

History. 1213. to be carried to extremities. He accordingly sent over two legates, Pandulf and Durand, who, in a meeting of parliament holden at Northampton, ventured to declare to John that he was bound to obey the holy see as much in temporal as in spiritual affairs. After shuffling, according to custom, John, at the head of an army capable of bidding defiance to any invader, surrendered himself to the will of the pope, and acceded to all the terms which Pandulf had exacted. With a meanness of spirit almost exceeding belief, he laid his crown at the feet of the haughty legate, resigned England and Ireland into the hands of the pope, swore homage to him as his liege lord, and took an oath of fealty to his successors. The terms of this remarkable oath deserve a place in every history.

"I John, by the grace of God king of England and lord of Ireland, in order to expiate my sins, from my own free will and the advice of my barons, *give* to the church of Rome, to Pope Innocent and his successors, the kingdom of England, and all other prerogatives of my crown. I will hereafter hold them as the pope's vassal. I will be faithful to God, to the church of Rome, to the pope *my master*, and to his successors legitimately elected. I promise to pay him a tribute of 1000 merks; to wit, 700 for the kingdom of England, and 300 for the kingdom of Ireland." This memorable submission took place on the 15th of May 1213.

This oath was taken by the king before all the people, kneeling, and with his hands held up between those of the legate. Having then agreed to install Langton in the primacy, he received the crown which he had been supposed to have forfeited; whilst the legate, to add to his former insolence, trampled under his feet the tribute which John had consented to pay, but afterwards stooped to gather it up. The king of France was enraged at this behaviour of the pope, and resolved to execute his project of conquering England in spite of him and his censures. His fleet, however, was attacked in their harbours by the English, who took three hundred vessels, and destroyed about a hundred more; whilst Philip, finding it impossible to prevent the rest from falling into the hands of the enemy, set fire to them himself, and thus abandoned the enterprise. This naval action is memorable as being the first which took place between the fleets of France and England, and was a good omen for the latter.

John being thus delivered from all danger, continued to follow the same cruel and tyrannical measures which had hitherto rendered him odious to his subjects. His scandalous subjection to the clergy now gave the barons an opportunity of exerting themselves, in order to reduce the enormous prerogatives of the crown. Their designs were greatly facilitated by the concurrence of Langton the primate, who on all occasions showed a sincere regard for the interests of the kingdom. At a synod of his prelates and clergy, convened in St Paul's on pretence of examining into the losses of some bishops who had been exiled by John, he privately conferred with a number of barons, to whom he expatiated upon the vices and injustice of their sovereign. He showed them a copy of Henry I.'s charter, the only one in the kingdom, having been found amidst the rubbish of an obscure monastery. Langton exhorted the barons to insist on a renewal thereof; and this they solemnly swore to perform. The same agreement was afterwards renewed at a more numerous meeting of barons summoned by Langton at St Edmondsbury. Here it was resolved that at Christmas they should prefer their common petition in a body, and in the mean time they separated, intending to put themselves in a posture of defence, to enlist men, and to make other warlike preparations. In the beginning of January 1215 they repaired to London, accoutred in the military garb and with their equipage, and presented their petition to the king, alleging that he had promised to grant a confirmation of the laws of Edward the Confessor, at the time when he was absolved from his excommunication. John resented their presumption; and required a promise under their hands and seals that they would never demand or attempt to extort such privileges in future. But this they refused with such unanimity and resolution, that the king desired time to consider of their petition; at the same time promising that, at the festival of Easter, he would give a positive answer. He also offered securities, which the barons accepted, and thereafter withdrew. History. 1215.

John, however, had no intention of complying with their demands, for it is evident that his promise was extorted from him by fear. He had recourse to the clergy, whose favour he propitiated by promising many things which he had not the slightest intention of ever performing. The pope was likewise appealed to, who threw the weight of his authority into the scale of his vassal, and exhorted the barons to abandon their treasonable enterprise. At the same time his holiness also agreed to consider their petition, and to endeavour to obtain for them the concession of those demands which appeared to be just. But, happily for English liberty, the confederates disregarded the injunctions of Innocent III., who by his decision had now more embroiled the fray. Both parties gave up all hopes of a peaceful negociation at the ensuing festival, and made the best preparations they could for war, in which the barons had an unequivocal superiority.

After waiting until Easter, when the king promised to return them an answer, they met by agreement at Stamford. There they assembled a force of above two thousand knights, with a prodigious number of foot, and thence marched to Brackley, about fifteen miles from Oxford, then the court residence. John, hearing of their approach, sent the Archbishop of Canterbury, the Earl of Pembroke, and others of his council, to know the particulars of their request, and what those liberties were which they so much importuned him to grant. The barons delivered a schedule containing the chief articles of their demands, founded on the charters of Henry and Edward, but which were in the highest degree displeasing to the king. He burst into a furious passion, and, asking the barons why they did not also demand his kingdom, swore that he would never comply with such exorbitant requests. The confederates then as their general chose Robert Fitzwalter, whom they dignified with the title of Mareschal of the army of God and of the holy church. They laid siege to Northampton, but were repulsed; they, however, took Bedford, and were joyfully received into London.

The concurrence of the metropolis proved decisive of the contest. It was in vain that the pope fulminated a bull in favour of his vassal John; the many were unanimous, and the few were compelled to yield the point. The king, with a court now reduced to seven attendants, retired to Odiham, where, seeing the necessity of submitting, he agreed to a friendly conference. The barons named, as a proper place for meeting, Runnymede. It was a meadow situated between Staines and Windsor, and, like the holy ground of the Hebrews, it is still held in veneration as the spot where the standard of English freedom was first unfurled. On the 15th of June 1215, both parties met there; and having taken up separate stations, a long discussion ensued, which terminated in the king signing the charter, called, by way of pre-eminence, Magna Charta. For a particular account of the great charter, which for centuries afterwards was looked upon as the palladium of our national freedom, the reader is referred to the article MAGNA CHARTA.

This charter, however, at the time when it was granted,

History. 1215. secured liberty to the clergy, the barons, and the gentlemen, much more than to the bulk of the people, who did not for a long time obtain any privileges of importance. Freedom of elections was secured to the clergy; and it was determined that fines imposed on them for any offence should be laid on in proportion to their estates, and not the value of their benefices. The privileges secured to the barons were, either abatements in the rigour of the feudal laws, or relief from arbitrary and ambiguous decisions before the courts. It was also decreed that barons should recover the lands of their vassals, even though forfeited by felony, after having been in the possession of the crown for a year and a day; and no tax was to be imposed without consent of the great council of the nation, excepting in case of the captivity of the king, the knighting of his eldest son, or the marriage of his eldest daughter. No land belonging to any baron was to be seized for a crown debt, except when the possessor had not personal property enough to pay it; neither was any vassal to be allowed to sell so much of his land as to incapacitate him from performing the necessary service to his lord. It was also determined, that when the great council of the nation was called, the prelates, earls, and barons should be summoned by a particular writ, and that the lesser barons should receive a summons from the sheriff. In favour of the people it was stipulated, that they should receive from the barons all the immunities and privileges granted by the king to the former. Merchants were to be allowed to carry on their business without any arbitrary tolls or impositions, and to go out of the kingdom and return at pleasure. The goods of every freeman were to be disposed of according to his will; or if he died intestate, the nearest heir was in that case to succeed him. No carts, horses, or wood were to be taken by the crown officers without the consent of the owner. The king's courts were to be stationary; no delay was to take place in doing justice to every one; and no freeman was to be taken or imprisoned, dispossessed of his free tenement, outlawed, or banished, unless by the legal judgment of his peers. It was likewise stipulated that London should remain in the hands of the barons, and that the Tower should be consigned to the primate, till the 15th of August following, or till the articles contained in the charter were fulfilled. In order to secure the accomplishment of this, the king allowed them to choose twenty-five of their own number, to whose authority no limits were assigned. If any complaint were made of a violation of the charter, either by the king or his officers, any four of the barons might admonish the king to redress the grievance; and if satisfaction were not obtained, they might assemble the whole council of twenty-five and, in conjunction with the great council, compel him to fulfil the charter. In case of his resistance, they had liberty to levy war against him, attack his castles, and use every kind of violence, except against his person, or those of his queen or children. All men throughout the kingdom were bound, under the penalty of confiscation, to swear obedience to the twenty-five barons; and the freeholders of each county were to choose twelve knights, whose business it was to report such obnoxious customs as ought to be redressed in terms of Magna Charta.

But although John had thus been obliged to recognise the liberty of his subjects, he had no mind that they should in reality enjoy it. The sense of his subjection to his own vassals sunk deep into his soul, and he became sullen, silent, and reserved. He shunned the society of his former friends, and retired into the Isle of Wight, as if to hide his disgrace in solitude, but, in reality, to meditate plans of revenge. He sent to the Continent in order to enlist a large body of mercenary troops, and made heavy complaints to the pope on account of the insurrections of the barons against him. The pontiff, as might be expected, warmly espoused his cause; a bull was sent over annulling the whole charter; the principal barons were excommunicated by name, and declared to be worse than Saracens; and at the same time the foreign troops arriving, the king once more found himself in a condition to demand his own terms from his untractable subjects. History. 1216.

The barons had made no preparations for war, not suspecting the introduction of a foreign army. The king, therefore, was for some time undisputed master of the field, and the most horrid cruelties were committed by his army. The nobility who had been most active in procuring the great charter accordingly fled with their families to Scotland, where they obtained the protection of King Alexander by doing homage to him. The barons, finding themselves totally unable to raise an army capable of contending with that of John, resorted to the equivocal and perilous expedient of calling in foreign aid. They applied to their old enemy Philip of France, offering the crown to his eldest son Louis, upon the condition of their being protected from the fury of John, and the unprincipled mercenaries whom he commanded. The French king eagerly accepted their proposals, and dispatched his son with a powerful army to England. He was received by the barons with great acclamations, and having united their forces, they secured all the southern counties. Essex and Sussex were soon after added; and they advanced successfully into Norfolk, spreading around them all the devastations of civil war. The forces of John occupied the northern districts, where the king of Scotland harassed him by an invasion of Northumberland. But these hostilities, which might ultimately have ruined the independence of the country, by sinking it to the level of a French province, were happily terminated by the death of John, in the forty-ninth year of his age, and seventeenth of his reign. His demise took place at Newark, on the 19th of October 1216. The death of this monarch was as much a public blessing as his reign had been a national misfortune. The signing of Magna Charta is the only event of his life which is worthy of being recorded in history. He, however, deserves no credit for that act, which was the result of compulsion. As well might we consider honesty the actuating principle or motive of the malefactor who consents to deliver up the treasure of which he had possessed himself, when he comes in sight of the wheel upon which, in case of refusal, he is to be broken alive.

John left six legitimate children, namely, three sons and three daughters. The eldest of the former, Henry of Winchester, was only ten years of age when he found himself in possession of the title, although not entirely of the power, of king. He was crowned as Henry III. upon the 28th of October 1216, nine days after he succeeded to the inchoate right to the throne. The care of his person was entrusted to the Earl of Pembroke, earl-marshal, with the style and title of guardian of the kingdom. Through the instrumentality of this nobleman the great charter of liberties was revived, and the claims of the crown were reconciled with those of the subject, to the satisfaction of the adverse barons. Besides the eldest son of John, there was another competitor for the crown, namely, Louis of France, who had been called over by the barons of Runnymede, in order to take possession of the English throne. For some time Louis kept the field, and not without success; but he was defeated at Lincoln; and a fleet which his father had sent to him with succours having been totally destroyed by the English, he was compelled to abandon the enterprise, and to make an honourable retreat.

A peaceful king is looked upon either as imbecile or as pusillanimous by an age which feels the intoxication of military glory, and considers the principal duties of a mo-

narch to be "to go out and in before his people, and fight their battles." The reign of Henry III. is but little adorned with the triumphs of war; and, if we are not mistaken, it has been too much depreciated on this account. But this fact, as well as his monarchical character, we will be enabled to ascertain with more certainty after we have passed in review the principal events of his reign. Its early history exhibits only some of those evils incident to an injudicious, but not, strictly speaking, wicked administration. In 1225 the great charter was a third time confirmed, upon the occasion of Henry assembling a great council, and urgently demanding aid against a pretended invasion of the French. In consequence of this, it has ever since retained its place at the head of English statutes. The wardship of the young king had now solely devolved upon Hubert de Burgh, the grand justiciary, and a man of ability and spirit, but nurtured under Richard and John. For several years he ruled as the favourite without control, repressing the disorders of the times with a vigorous, but, in the eye of an enlightened age, cruel policy. In 1227, Henry was declared in parliament to have attained to the years of discretion; and two years afterwards he resumed the project of conquering France, and landed there with a considerable army. The expedition proved most disgraceful to the English arms; and in a year after he returned to his country not a little humbled in its estimation, as well as his own. The next event of importance which we meet with is the disgrace of De Burgh, who was accused of negligence and treachery in the discharge of his duties; with what degree of truth it is difficult now to determine. He was imprisoned for some time, but afterwards restored to liberty, honours, and emoluments.

In 1236, Henry espoused Eleanor of Provence. This event gave rise to a new immigration of foreigners of higher rank and more specious pretensions than those who usually flocked to the soil of England. One of the queen's uncles became prime minister, a second was made primate, and a third Earl of Richmond. This favouritism excited much discontent both amongst the native barons and the people. The other events of this long reign consist of petty wars and bickerings with France, Scotland, and Wales. The prodigality of the king was extreme, and he was repeatedly compelled to lay his necessities before parliament and solicit supplies. These were as often afforded; but notwithstanding these grants, he had frequent recourse, under specious pretexts, to the most unjust exactions. Meanwhile England rapidly increased in wealth, and widely extended her commercial relations with other countries.

In the year 1254, at the instance of the pope, Henry accepted of the crown of Sicily for his son Edmund. It had been formerly offered to his brother Richard, who was wise enough not to accept of it, probably because he felt himself unable to compete with the other powerful princes who aspired to it. In order to raise the money necessary to carry his foolish project into execution, Henry had recourse to every expedient which the regal or papal ministers could devise. The principal burden fell upon the clergy, who, by the menace of excommunication on the one side, and of forfeiture on the other, were compelled to submit. This oppression widened more and more the breach between the king and his people; and he found it necessary at last to look to the security of his own crown, instead of fighting for a foreign diadem to grace the brow of his son.

Amongst the foreigners of distinction who established themselves in England during the reign of Henry III. was Simon de Montfort, earl of Leicester. He was the younger son of the Count de Montfort, celebrated in the annals of religious warfare for his cruel crusade against those dissenters from the Roman faith called Albigois or Albigenses. Simon the younger received the hand of King Henry's sister in marriage, and very early began to act a conspicuous part in the civil commotions which agitated the country. He was a bold and ambitious man; and placing himself at the head of the disaffected barons, he formed a powerful confederacy against the king. In the year 1258, a famous parliament was summoned at Oxford, in order to digest the new plan of government, and to elect to the chief authority such individuals as were deemed worthy of trust. This assembly, afterwards celebrated in our annals by the derisive name of the *mad parliament*, went very expeditiously to work in the business of reformation. Twenty-four barons were appointed, with supreme authority, in order to reform the abuses of the state; and Leicester was placed at their head. Twelve of these barons were chosen by the king's council, and twelve by the parliament. Their first step was to order four knights to be chosen out of each county, who should examine into the state of their respective constituents, and attend at the ensuing parliament to give information of their complaints. They ordained that three sessions of parliament should be regularly held every year; that a new high sheriff should be elected annually; that no wards nor castles should be entrusted to foreigners, no new forests made, nor the revenues of any counties farmed out. Thus far these provisions were good, and an approximation to popular representation, although some modern writers have designated the whole transaction as a revolution.

The twenty-four barons continued to conduct the affairs of government for several years; but they at last began to quarrel amongst themselves. The Earls of Gloucester and Leicester pursued opposite interests, and formed opposite parties, who eyed each other with mutual jealousy. Leicester, perceiving that his rival was likely to gain the ascendency, retired to France; but the balance was again restored in his favour by the union of Prince Edward with his friends. A short time after this event, the rival parties seem to have assumed, if not the reality, at least the appearance of unanimity. In 1262, Henry made a fruitless attempt to escape from the authority of the barons; but his son Edward remained firm to their cause, on account of his having sworn to observe the provisions of Oxford. After other ineffectual attempts upon the part of the king, he agreed that the twenty-four noblemen should continue to govern, not only during his own reign, but also during that of his successor. By this stipulation, Edward joined his father, which restored vigour to the royalists, and more equally balanced the power of the parties. It was proposed that the differences between them should be submitted for arbitration to Louis IX., and both swore to abide by his decision. That excellent monarch enjoined the restoration of all castles, possessions, and royal rights enjoyed by the crown before the parliament of Oxford, upon condition of universal amnesty, and of the full enjoyment of all the privileges and liberties granted by the charter. The award was confirmed by the pope, who empowered the Archbishop of Canterbury to excommunicate all who refused to submit to it.

The moment the decision was made known to the barons, they declared it to be contrary to truth and justice, and immediately took the field. The contest was at first favourable to the royal prerogative; but in 1264 Prince Edward lost a great battle by his impetuosity in pursuing too far one of the wings of the enemy's army, which he had defeated. His father and uncle were taken prisoners, and placed in the castle of Lewis, where he contrived to join them. They acceded to the propositions submitted to them, and the administration of the kingdom fell into the hands of the Earls of Gloucester and Leicester, and the Bishop of Chichester.

History. 1265.

The situation to which the kingdom was now reduced proved at last the means of settling the government upon a more proper foundation. Leicester, in order to secure himself, was obliged to have recourse to an aid, till now entirely unknown in England, namely, that of the body of the people. He called a parliament, where, besides the barons of his own party, and several ecclesiastics who were not properly tenants of the crown, he ordered returns to be made of two knights from every shire; and also deputies from the boroughs, which had been hitherto considered as too inconsiderable to be allowed any share in the legislation. This parliament was called on the 22d of January 1265; and here we find the first outline of an English House of Commons; an institution which has ever since been considered, and justly, as the bulwark of British liberty.

The new parliament was far from being so compliant to Leicester as he had desired or expected. Many of the barons who had hitherto stedfastly adhered to his party were disgusted with his boundless ambition; and the people, who found that a change of masters was not a change of circumstances, began to wish for the re-establishment of royal authority. Leicester at last, making a virtue of necessity, released Prince Edward from his confinement, and had him introduced at Westminster-hall, where his freedom was confirmed by the unanimous voice of the barons. But though Leicester had all the popularity of restoring the prince, he was yet politic enough to keep a strict watch over him. Edward was nominally free, but in reality a prisoner. At last, however, he found means to effect his escape. The Duke of Gloucester, being disgusted with Leicester, left the court, and retired to his estates upon the borders of Wales. His antagonist pursued him thither, and, in order to give the greater authority to his arms, carried the king and Prince Edward along with him. This afforded young Edward an opportunity which he had long desired of making his escape. Being furnished by the Earl of Gloucester with a horse of extraordinary speed, he took leave of his attendants, or rather his guards, under pretence of trying the mettle of his steed. He was hotly followed; but an end was put to the pursuit by the appearance of some of Gloucester's troops.

No sooner was the prince at liberty than the royalists joined him from all quarters, and an army was soon assembled which proved more than sufficient to meet the forces of Leicester. The latter now found himself in a remote quarter of the kingdom, surrounded by his enemies, and shut out from all communication with his friends by the river Severn, the bridges on which Edward had broken down. In this extremity he wrote to his son to hasten to his assistance from London, with a considerable body of troops which the latter had under his command. With this view his son advanced to Kenilworth; but here he was surprised by Prince Edward, and the greater portion of his followers were made prisoners. The young prince immediately advanced upon Leicester himself, whose last anchor had given way with the defeat of his son. He was by no means able to cope with the royalists; his men were inferior both in numbers and resolution to their antagonists. In the battle which ensued, the royalists gained a signal victory over their opponents, defeating them with great slaughter. Leicester himself was slain, together with his eldest son Henry, and about a hundred and sixty knights and other gentlemen. The body of the fallen earl was mutilated in a frightful manner, and portions of it sent to various places. His memory was long revered by the people, who looked upon him as a martyr to the liberties of the realm. But a vigorous reign ensued, and the national feeling was suppressed, or directed to other objects. He left, however, an imperishable name, as the first who had called together a parliament of which the lower house composed part.

History. 1286.

The victory of Evesham restored the fortunes of the royalists. The followers of Leicester were proscribed, and their lands distributed amongst the victors. With the death of Montfort the spirit departed from the baronial party, whose members hastened to give in their submission, and to open the gates of their castles to the king. Several places, however, still held out; but by the activity and valour of Prince Edward they were all finally reduced. The country submitted, and the royal authority was completely re-established throughout the realm. The good sense of Edward, however, infused a wiser and more popular spirit into the conduct of government. So judicious appears to have been his administration, indeed, that, in a few years after the battle of Evesham, he felt himself in a capacity to take the cross, and enlist under the banners of the crusaders. This step of the heir apparent to the crown of England may appear somewhat extraordinary, when we consider the advanced period of life to which his father had now attained, and the civil commotions from which he had so recently emerged. But in an age when it was common to ascribe any sudden transition of fortune from one extreme to another, to the immediate interposition of providence, it is less to be wondered at. The recent deliverance of himself and his father from their enemies had incurred a debt of gratitude to heaven which it was now his desire to pay off. His expedition to the Holy Land was of little importance, and was moreover in no way connected with the history of his country, although it was distinguished by those romantic adventures and chivalrous feats of arms peculiar to the age, and more especially to the wars in Palestine.

The remaining events of Henry III.'s reign afford no materials for history. He died on the 16th of November 1272, in the fifty-seventh year of his reign. The character of Henry is not strongly marked either by good or by evil. During its long continuance we see no premeditated crime, no deep laid plot involving the liberties of his subjects, with which to impeach his memory. The evils which grew and prospered whilst he held the sceptre did not arise from vices in the sovereign, but from the unsettled state of society and the turbulent spirit of the times. His virtues, however, were not very conspicuous; they were rather of a passive than of an active kind; rather the negative of vice than positive moral greatness. With regard to intellect, he appears to have been below mediocrity; and it is usual with historians to describe him as deficient in capacity to govern. This was probably the case, but it was productive of inconvenience to himself rather than misery to his subjects. Under his pacific rule, as we have already observed, the nation grew more rapidly in wealth and prosperity than it did under the more dazzling sway of his military progenitors.

Edward, upon hearing the news of his father's death, and feeling himself secure of the throne, returned slowly from the Holy Land. He arrived in England in August 1274, and was crowned at Westminster on the 19th of the same month. Two years afterwards he undertook an expedition against Lewellyn, prince of Wales, who had refused to do homage for his crown. The conquest of that country cost him some trouble, and was not completed until the year 1283. After this period the principality of Wales was annexed to the crown of England, and thenceforth conferred a title upon the king's eldest son. In 1286, Wales had been so entirely broken into subjection, that Edward undertook a journey to the Continent for the purpose of mediating a peace between Alonzo of Aragon and Philip the Fair of France. These two monarchs had differed

History. 1286.

about the kingdom of Sicily: but a negociation was effected, and the king of England returned to his country after an absence of three years, during which period much disorder had been introduced into his dominions. Robbery and violence had become frightfully prevalent, and the corruption of the judges had poisoned the fountains of justice. In order to remedy these evils, Edward summoned a parliament, and cited the delinquents to appear and take their trial. All of them, except two clergymen, having been convicted of flagrant acts of corruption and bribery, were accordingly fined, and deposed from their office.

The next great event of Edward's reign was an attempt to subjugate Scotland. This he never altogether effected, although he succeeded in reducing the country to great distress, and in even nominally attaching it to the English crown as a conquered province. For an account of these transactions, see the article SCOTLAND. Edward was at the same time engaged in expensive contests with France; and these multiplied wars, by obliging him to have frequent recourse to parliamentary supplies, became the remote causes of great and important changes in the government. The parliament was modelled into the form which it has ever since retained. As a great part of the property of the kingdom, by the introduction of commerce and by improvements in agriculture, was transferred from the barons to the lower classes of the people, so their consent was thought necessary in order to raise the supplies. For this reason the king issued writs to the sheriffs, enjoining them to send to parliament, along with two knights of the shire, two deputies from each borough within their county; and these, too, provided with sufficient powers from their constituents to grant such demands as they should think reasonable for the safety of the state. The charges of these deputies were to be borne by the boroughs which sent them; and so far were they from considering this deputation as an honour, that nothing could be more displeasing to any borough than to be thus obliged to send a deputy, or to any individual than to be thus chosen. The authority of these commoners, however, increased in course of time. Their union gave them weight; and it became customary among them, in return for the supplies which they granted, to prefer petitions to the crown for the redress of grievances. The more the king's necessities increased, the more he found it necessary to give them an early hearing, until, from requesting, the commons proceeded to demanding; and having all the property of the nation, they by degrees began also to be possessed of a considerable share of the power.

Edward I. died of a dysentery, near Carlisle, on the 7th of July 1307, as he was leading a great army into Scotland, against the inhabitants of which he had vowed the most dreadful vengeance. Edward ranks amongst the greatest monarchs of England. In military talents, in sound judgment, in vigour, decision, irascibility, and vindictiveness, he bore some resemblance to the Conqueror. Like him too he possessed an unsatiable ambition, and his unholy crusade against the independence of Scotland must be regarded as an indelible blot upon his memory. He was succeeded by the eldest of his surviving sons, who bore his father's name, but inherited nothing of his capacity, and who was crowned on the 8th of July 1307, with great magnificence. His father had charged him upon his death-bed to prosecute the war against Scotland until he had finally subdued the kingdom; but war had few attractions for Edward II., and he withdrew his army ingloriously from the country which his father went to subjugate. The first years of Edward's reign are distinguished for nothing but bickerings with his barons, who finally extorted from him a reformation of abuses in full parliament. The Scots in the mean time gradually recovered their power; and Edward having invaded their country with a prodigious force, was met by Robert Bruce at Bannockburn, near Stirling, who totally defeated the puissant army of the English on the 24th of June 1314. See SCOTLAND.

History. 1326.

The reign of Edward II. was one continued series of quarrels with his turbulent subjects. His favourites were the most general causes of discontent. The first of these was one Pierce Gaveston, the son of a Gascon knight of some distinction. The latter had honourably served the late king, and, in reward for his services, had obtained an establishment for his son in the family of the Prince of Wales. To be the favourite of any king whatsoever is no doubt in itself a sufficient offence to the rest of the courtiers. Numberless faults were therefore found with Gaveston by the English barons. When the king went over to France to espouse the Princess Isabella, to whom he had been long contracted, Gaveston was left guardian of the realm, with more ample powers than had usually been conferred in such cases. But upon the arrival of the queen, who was of an imperious and intriguing spirit, Gaveston had the misfortune to fall under her displeasure, on account of the ascendency he had acquired over the king. A conspiracy was soon formed against the favourite, at the head of which was the queen and the Earl of Lancaster, a relation of the king's, and the most powerful nobleman in England. Edward found himself unable to protect his favourite against such a formidable combination, and was compelled to banish him. His recall some time afterwards again spread alarm over the country, and kindled a civil war. The nobility were successful in obtaining possession of the obnoxious Gaveston; and, in order to free themselves for ever from uneasiness on his account, they put him to death.

After the defeat of Bannockburn, King Edward chose a new favourite named Hugh le Despencer. He was a young man of a noble English family, and possessed some merit, and engaging accomplishments. His father was a person of apparently unimpeachable character, but he also enjoyed the king's favour, and that was a sufficient crime. The king imprudently dispossessed some lords of their estates, in order to bestow them upon young Despencer. This afforded a sufficient pretext to the barons for openly attacking both the father and son. The Earls of Lancaster and Mortimer, chief of the Welsh marshes, flew to arms; and sentence of perpetual exile against the two Spencers, with a forfeiture of all their estates, was procured from parliament. At last the king took the field, and obtained a signal victory over the other party at Boroughbridge. The Earl of Lancaster was made prisoner, and beheaded a few days afterwards at his own castle of Pomfret. This individual was canonized in 1389. Many other noblemen suffered the same punishment without having the same respect paid to their memory, whilst Mortimer was condemned to perpetual imprisonment.

The triumph of the Spencers was now complete; but the partiality with which the king regarded his two favourites had the effect of alienating not only the affections of his subjects, but also those of his queen. Other charges are brought against Edward as having contributed to effect this estrangement, and Isabella sought an opportunity of escaping from her husband. The palace of her brother at Paris was her natural place of refuge. A rupture having commenced between England and France, the queen proceeded to the court of the latter as negociator, and concluded a peace humiliating to her husband. But she had another object in view in visiting her native country. Her residence became a sanctuary for the English malcontents, who flocked to her in great numbers; and

History. 1326.

amongst these came Mortimer, who had contrived to effect his escape, and for whom she has been charged with entertaining a stronger passion than that of friendship. The cause of quarrel between the two powers was the county of Guienne, for which the monarch of France required Edward to do homage and fealty. The disputed territory was resigned to the young Prince of Wales, who joined his mother, and made the necessary submissions. When Isabella considered that matters were sufficiently matured for executing her purpose, she landed in England on the 22d of September 1326, where she was universally welcomed, and immediately joined by the most potent barons. The unfortunate king found that the spirit of disloyalty had spread over the whole kingdom. Some dependence was placed upon the garrison of Bristol, which was commanded by the elder Spencer; but the soldiers rebelled against their governor, and delivered him into the hands of the barons, by whom he was cruelly put to death. Young Spencer did not long survive his father. Along with some others who had followed the fortunes of the wretched king, he was made prisoner in an obscure convent in Wales; and the queen having no patience to wait the formality of a trial, gave orders for his immediate execution.

In the mean time the king was discovered and delivered up to his adversaries, who loaded him with insults. He was conducted to the capital, and consigned to the Tower. The charge against him exhibited no other crimes than his incapacity to govern, his indolence, his love of pleasure, and his accessibility to evil counsel. His deposition was quickly voted by parliament; he was assigned a pension for his support; his son Edward, a youth of fourteen, was appointed to succeed him, and the queen was nominated regent during the minority. But the deposed monarch did not long survive his disgrace. He was at first put into the custody of the Earl of Lancaster; but this nobleman having shown some marks of respect and pity for the misfortunes of his sovereign, the latter was taken out of his hands and delivered over to the Lords Berkeley, Maltravers, and Gournay, who were entrusted alternately, each for a month, with the charge of guarding him. Whilst he was in Berkeley's custody, he was still treated with some degree of humanity; but when the turn of Maltravers and Gournay came, every species of indignity was practised upon him, as if they had designed to accelerate his death by accumulating his mental sufferings. As his persecutors, however, saw that his death might not speedily arrive, even under every cruelty which ingenuity could devise, and as they were daily afraid of a revolution in his favour, they determined to put their fears to rest by destroying him at once. Mortimer, therefore, secretly gave orders to the two keepers to dispatch the king; and these ruffians contrived to render the manner of his death as barbarous as possible. Taking advantage of Berkeley's sickness, in whose custody he then was, and who was thereby incapacitated from attending to his charge, they came to Berkeley Castle, and obtained possession of the king's person. They threw him on a bed, and held him down with a table which they had placed over him. They then ran a horn pipe into his bowels, through which they conveyed a red-hot iron; and thus deprived him of life without disfiguring his body. The murderers fled on the perpetration of this horrible enormity; for the dying agonies of the king created suspicions which ended in the discovery of the crime. One of the fugitives was taken at Marseilles, and beheaded on his way to England. The other concealed himself for some years in Germany; but having found means of rendering some services to Edward III. he ventured to approach the person of that monarch, and by his humiliating submission received a pardon.

History. 1327.

By the death of Edward II. the government fell entirely into the hands of the queen and Mortimer, who had now the disgraceful pre-eminence of royal paramour. The parliament, which had raised young Edward to the throne, had indeed appointed twelve persons as his privy council, to direct the operations of government. Mortimer excluded himself, under a show of moderation; but at the same time secretly influenced all the measures which came under their deliberation. As this influence began very soon to be perceived, and the queen's criminal attachment to Mortimer was universally known, the administration soon became obnoxious to the people. It had continued four years, when a circumstance occurred which added greatly to its unpopularity. The Scots having made an irruption into England, were met by an overwhelming force under young Edward, or rather Mortimer. The results of this mighty expedition were most ludicrous. By their superior skill and activity, the Scots foiled the English commanders, and made their escape into their own country. Soon after this inglorious campaign, a solemn treaty of peace was concluded, in which Edward, for a sum of money, renounced every claim of superiority over Scotland. This, although a commendable act of moderation, was not calculated to propitiate the favour of the English people. It was not long before another stroke of Mortimer's power and policy startled the nation from its propriety, and paved the way for his own destruction. Amongst those who began to betray indignation against the encroaching spirit of Mortimer, was Edmund earl of Kent, who, deceived into a belief that his brother Edward II. was still alive, wrote a letter to that prince, which was betrayed into the hands of Mortimer, now Earl of March, by the individual who had undertaken to deliver it. The writer of the epistle was immediately tried for high treason, condemned, and executed. There is little doubt that the whole affair of the letter was a plot laid for the destruction of Kent, not only to get him out of the way, but to show that there was no one too high not to be struck down by the vengeance of Mortimer.

Edward finding the restraint under which he was retained becoming irksome, resolved to shake it off, and to rid himself and the nation at once of an authority which had now become alike odious to both. The queen and her paramour had repaired to Nottingham, where a parliament was then held. They had chosen the castle as a place of residence, and taken every precaution to ensure their safety; for fear follows guilt like its shadow. The enemies of Mortimer, however, found means to obtain admission at dead of night; and having seized him as he lay in an apartment adjoining to that of the queen, he was taken prisoner to London, tried before his peers for various crimes, convicted, and executed.

The queen, who was perhaps the most culpable of the two, was screened from capital punishment by the dignity of her station, but stripped of all power, and confined for life to the castle of Risings. From this imprisonment she was never liberated, but during her life the king paid her an annual visit of ceremony.

Edward III. proved one of the greatest warriors who had ever sat on the English throne. His first attempts were to raise Edward Baliol to the throne of Scotland: this however he failed in effecting. But his mind now began to be diverted to loftier and more ambitious speculations. The crown of France became the object of contest between Edward, the son of Philip the Fair's daughter Isabella, and Philip of Valois, the son of the brother of Philip. The question was, whether the crown was descendible only through males, or whether it might be claimed by the nearest male although his descent was by females. Charles the Fair died in 1328, and left the crown of France with-

History. 1327.

out direct male descendants to inherit it. The three last kings were the sons of Philip the Fair, and they all reigned successively, but died without issue. According to the English law, the son of the daughter precedes the nephew in inheritance; but the French Salic law excluded females. Edward contended that the feudal laws of France forbade females to inherit who could not perform the feudal duties, yet that their male heirs were not debarred by the spirit of this law, because they were competent to discharge all the military services required. On the other hand, it was insisted by the French advocates for Philip de Valois, that the exclusion of the female in the first instance was an exclusion of all the descendants of either sex. If it had been a question of succession to the English crown, it would have been rightfully determined by the parliament and law of England; but as it concerned the crown and law of France, it was clearly a matter for the French state and lawyers to decide. They decided in favour of Philip de Valois, and he was accordingly crowned king of France. In this decision they displayed the soundest principles of national policy, and Edward ought undoubtedly to have acquiesced.[1] The king of England, however, thought otherwise, and accordingly began to make preparations for an invasion of France.

By doing homage to Philip for the duchy of Guienne, Edward gained time to collect such an army and treasure as were necessary for the enterprise. Two powerful continental allies appeared in his favour; namely, Robert of Artois, who had been excluded from the county to make way for his aunt Matilda, a nearer relative by blood to the preceding count; and James von Artaveldt, a famous brewer of Ghent, and leader of the democratical party among the Flemings. It was at the suggestion of the latter that Edward assumed the title of king of the French, as a pledge that he would pursue his undertaking with inflexibility of purpose. The king of England landed at Antwerp in July 1338; but it was not until more than a year thereafter that he reached the confines of France. His first campaign was unimportant, but in the second he achieved a considerable naval victory on the 22d of June 1340. Flushed with this success, he marched to the siege of Tournay at the head of 100,000 men. Near this town the king of France had encamped himself in a situation so strong as to bid defiance to attack. Edward challenged him to single combat, but this was refused; and the English were at last compelled to raise the siege, and to retire sullen and discontented from the place.

The efforts of Edward began now to be much crippled for want of money. The exchequer of England was unable to satisfy his demands, and his allies had become clamourous for their arrears. Some of his courtiers having instilled into his mind suspicions of the fidelity of his ministers, he suddenly returned to London, where he landed about midnight at the Tower. Next morning he displaced the chancellor, treasurer, and master of the rolls, confined three of the judges, and ordered the arrest of most of the officers employed in the collection of the revenue. Archbishop Stratford, however, boldly opposed his career of resentment and cruelty, and vindicated the cause of the ministers. The king was compelled at last to abandon his process against the primate, for the urgency of his wants admitted of no delay.

The failure of his first two campaigns did not wean Edward from his attachment to foreign alliances. By a disputed succession to the duchy of Brittany, in which he took the part of the individual who opposed Philip of France, a new road was opened up to him into that country. He collected a vast army, with which he landed near Cape la Hogue about the end of July 1346. His career in France was a series of triumphs most glorious to the English arms. On the 26th of August 1346 was fought the decisive battle of Cressy, which is still memorable after the lapse of many centuries. In this celebrated conflict, Edward the Black Prince, a youth only sixteen years of age, gained unfading laurels. The siege of Calais followed, and the place was reduced after an obstinate defence. The first fruit of the reduction of this place was a truce, which lasted till 1355, when Edward the Black Prince, who governed his father's dominions in France, undertook an expedition into the neighbouring provinces, and in the following year carried his arms into the heart of France. The victory of Poitiers was another mortifying humiliation to the French. John their king was taken prisoner, and treated with noble hospitality and respect by his renowned conqueror. He was conveyed to England, where his reception resembled rather the return of a victorious prince than the humiliation of a captive monarch. For a particular account of these and other transactions of the English in France, the reader is referred to the article France.

History. 1376.

During the absence of the king of England on the Continent, his country was harassed by the Scots, who invaded it, but experienced a defeat at Nevelles Cross. In 1355, Edward himself invaded Scotland; and the havoc caused by this expedition was long remembered by the natives. The death of Edward Baliol in 1364 left David Bruce without a rival to the Scottish throne; and the pretensions of the Plantagenets to Scotland were terminated by Edward III.'s recognition of his brother-in-law. See Scotland.

In the mean time Edward the Black Prince, after a Spanish campaign, in which he gained the celebrated battle of Navarete, returned to England in pursuit of health and quiet. But thirty years of toil and war had exhausted his robust frame, and he expired at Canterbury on the 8th of June 1376, in the forty-sixth year of his age. He left behind him a lofty reputation for bravery and skill as a commander, generosity as a knight, and wisdom and vigour as a statesman. His father Edward III. did not long survive his loss. He died on the 21st of June the year following. The reign of this monarch is generally considered by Englishmen as the most illustrious period of their ancient annals. "The victories of Cressy and Poitiers," says Mr Turner, "may have produced the popular sentiment; but the reflective mind will adopt the opinion as steadily, when it observes, during this reign, that our navy established its preponderance over the most celebrated fleets that were then accustomed to navigate the British channel; that our parliament enjoyed, in full and upright exercise, those constitutional powers which the nation has long learnt to venerate as its best inheritance, but which weaker sovereigns have too eagerly contested; that our manufactures and commerce began to exhibit an affluence and an expanding growth, and to be conducted on the true principles of public improvement; that our clergy evinced a disposition to emancipate themselves from the papal despotism, and some to exercise a just freedom of thought on the most important of all human concerns; that the lineaments of our prose literature became distinctly discernible; that the pursuit of the mathematical and natural sciences, and of the art of reasoning, at one or both of our venerable universities, was ardent and successful; that our poetry assumed the attractive form with which its life, sympathy, utility, and immortality are most surely connected; and that our manners displayed a moral sentiment, which, though somewhat fantastic, and al-

[1] Turner's *History of England*, vol. ii. p. 144.

History. 1377. ways pure, yet contributed to soften the horrors of war, and has led to that more cultivated feeling which, continually increasing and refining, has made Englishmen distinguished for their generosity, magnanimity, and honour." It may be added, on the authority of Sir Mathew Hale, that during this reign the law was greatly improved, and nearly attained its meridian. The monarch himself kept pace with the progress of the time, and his reign was sufficiently protracted to afford opportunities for the development and consolidation of all improvements. He left his country ennobled in the eyes of Europe, and possessed of gigantic energies capable of realising the glorious destinies which awaited her.

Edward III. was succeeded by Richard II. son of the beloved Black Prince. He commenced his reign, being only eleven years of age, on the 22d of June 1377, with many expressions of congratulation from his subjects. His coronation took place on the following year, and parliament was opened with a speech from the Archbishop of Canterbury, which, being "soothing and gracious," was meant to propitiate the favour of the representatives of the nation in behalf of the young sovereign. The Dukes of Lancaster, York, and Gloucester, uncles to the king, with some other noblemen, were appointed regents during Richard's minority. The war, which was still prosecuted in France on a small scale, and the expenses necessary for retaining the towns already taken, required supplies of money, which could not be raised without additional taxation; and this gave rise to much discontent amongst the people. An imposition of three groats upon each person of both sexes and every condition who had passed the age of sixteen, particularly excited the minds of the common people against the government. The manner, too, of collecting this tax, soon furnished an occasion of revolt. The insurrection began in Essex, where a report was industriously spread that the peasants were to be destroyed, their houses burned, and their farms plundered. At Dartford, an individual, well known by the name of *Wat Tyler*, was the first who excited the malcontents to arms. The tax-gatherers proceeded to this man's house whilst he was at work, and demanded payment for his daughter. He refused to comply, on the ground that she was under the age stipulated in the act; upon which one of these fellows offered to prove the contrary in a very indecent manner, and for this purpose laid hold of the maiden. Such insolence, however, roused the spirit of the father, and with one blow he laid the ruffian dead at his feet. A shout of applause burst from the bystanders, who declared themselves prepared to protect Wat from the vengeance of his enemies. The cry of the men of Kent was responded to by those of the neighbouring counties, and Wat soon found himself at the head of an enormous body of insurgents. They advanced to Blackheath in the month of May 1381, and proceeded to enforce their counsels by an attack upon London, in which they succeeded. The king, finding that resistance was vain, agreed to listen to their demands. On this they made a very humble remonstrance; requiring a general pardon, the abolition of slavery, freedom of commerce in the market-towns, and a fixed rent instead of those services required by the tenure of villenage. The king granted all these requests; and charters were made out by which the grant was ratified. In the mean time, another body of these insurgents had broken into the Tower, and murdered the chancellor, the primate, and the treasurer, with some other officers of distinction. They then divided themselves into parties, and took up their quarters in different parts of the city. At the head of one of these was Wat Tyler, who led his men into Smithfield, where he was met by the king, who invited him to a conference, under pretence of hearing and redressing his grievances. Tyler ordered his companions to retire till he should give them a signal, and boldly ventured to begin a conference with the king in the midst of his retinue. His demands were, that all slaves should be set free, that all commonages should be open to the poor as well as to the rich, and that a general pardon should be granted for the late outrages. During the interview, the rebel kept playing with his dagger, and at last he is said to have laid his hand on the bridle of his sovereign's horse; upon which Walworth, lord mayor of London, alarmed for the king, plunged a basillard in the throat of Tyler, and at the same moment another esquire dispatched him with his sword. This is the tale told by the writers of the victorious party, for the partizans of Wat Tyler had no historian to give their version of the story. The insurgents who witnessed the fall of their leader bent their bows with the design of revenging his death. But Richard, though only sixteen years of age, with admirable presence of mind galloped up to them, exclaiming, "What are you doing, my lieges? Tyler was a traitor. Follow me, and I will be your leader." With sullen and wavering discontent they followed him into the fields at Islington, where a body of troops had been collected for the protection of the young king. The insurgents were ordered to return to their homes instantly, and under the penalty of death they were forbidden to skulk about the city during night. But the whole of the rebels did not thus escape, and the revolt was not finally extinguished without much bloodshed and cruelty.

History. 1386. The courage, address, and presence of mind which the king had discovered in quelling such a dangerous tumult, gave great hopes to the nation: but, in proportion as Richard advanced in years, these hopes began to wither; and his want of capacity, or at least of solid judgment, appeared in every enterprise which he attempted. The king had unluckily lost the favour of the common people after the insurrection just mentioned. He allowed the parliament to revoke the charters of enfranchisement and pardon which had been granted; some of the ringleaders in the late disorders had been severely punished, and others were put to death without any form or process of trial. Thus the popular leaders were greatly exasperated by this cruelty, though probably the king did not in this follow the dictates of his own mind so much as the advice of his counsellors. But having thus lost the favour of one party, he quickly afterwards fell under the displeasure of the other also. Conceiving himself to be in too great subjection to his uncles, particularly the Duke of Gloucester, he attempted to shake off the yoke, by raising others to an equal share of rank and favour. Accordingly one of his favourites, Michael de la Pole, was created Earl of Suffolk, and raised to the chancellorship; whilst another, Robert de Vere, earl of Oxford, a young man of an agreeable person, but dissolute in his behaviour, soon acquired an absolute ascendency over him. This nobleman was first created Marquis of Dublin, and afterwards Duke of Ireland, both preposterous and invidious titles. The duke having soon become the dispenser of all the king's favours, a conspiracy was formed against him by some of the most powerful nobility in the kingdom. The Earl of Suffolk was impeached in parliament, and, being convicted of certain charges brought against him, was condemned to pay a suitable fine. Soon afterwards the king was prevailed upon to vest the government in the hands of eleven commissioners along with the three great officers of state. This measure was carried into effect by the Duke of Gloucester, who stood at the head of the committee; and the king could not without regret perceive himself thus totally deprived of authority. He first endeavoured to gain over the parliament to his interests, by

History. 1386. influencing the sheriffs of each county, who were then the only returning officers; and this measure failing, he next applied to the judges, who declared that the commission which had deprived the king of his authority was unlawful, and that those who procured or advised it deserved condign punishment; but their sentence was quickly opposed by declarations from the lords. The Duke of Gloucester armed his partizans, and appeared at the head of a body of men sufficient to intimidate both the king and his adherents. These insurgents, sensible of their own power, began by demanding of the king the names of those who had advised the adoption of the late rash measures. A few days afterwards they appeared armed in his presence, and accused by name the Archbishop of York, the Duke of Ireland, the Earl of Suffolk, and Sir Robert Tresillian, one of the judges who had declared in his favour, together with Sir Nicholas Brembre, as public and dangerous enemies to the state. The parliament which met on the 3d of February 1388 condemned the five accused persons to suffer the death of traitors. The Duke of Ireland escaped to Flanders, where he expired four years afterwards; De la Pole died at Paris in the same year; Tresillian and Brembre were put to death, and the Archbishop of York became a Flemish curate, and died in that humble capacity. The other individuals who had subscribed the bold opinion were condemned to perpetual imprisonment; with the exception of Black, who had drawn up the questions, and Usk, appointed under-sheriff to arrest the Duke of Gloucester, who were both executed.

But the king became restive in the traces with which his uncle restrained him. In a meeting of parliament he declared himself competent to manage his own affairs, as he had by this time attained his twenty-second year. This bold announcement was followed by his ordering Thomas Arundel, whom the commissioners had recently appointed chancellor, to give up the seals, which, on the following day, he delivered into the hands of William Wickham, bishop of Winchester. The council was next cleared of the Duke of Gloucester, the Earl of Warwick, and other opposition lords; and the great officers of the household, as well as the judges, were changed for more pliable instruments.

Being now his own master, Richard notified by proclamation that he had taken the reins of government into his own hands; and, whether it was owing to the king or his ministers, it must be owned that for some years his administration was tranquil and happy. During this halcyon period he made a journey into Ireland, in order to divert the melancholy with which he was afflicted on account of the loss of his wife Anne. Soon afterwards he espoused Isabella, a princess of France, then in her eighth year, which contributed to an armistice with that kingdom for twenty-five years.

This alliance with the royal family of France encouraged Richard to execute a scheme of vengeance which he had long nourished in his bosom against Gloucester and others who had been instrumental in the punishment of his favourites. The duke, with the Earls of Warwick and Arundel, were appealed for treason; in consequence of which the former was sent prisoner to Calais, and the two latter committed to the Tower. Here the head of Arundel was shortly after struck off, and Warwick was banished; but the fate of the Duke of Gloucester is involved in some obscurity. On the 21st of September 1397 a writ was issued to Thomas Mowbray, earl marshal, governor of Calais, commanding him to bring the body of his prisoner, the Duke of Gloucester, to answer before the king in parliament to the appeal of treason against him. The reply of the governor of Calais was, that the prisoner had died in his custody. At a subsequent period circumstances transpired which indicate that the duke perished by the foulest murder, doubtless at the instigation of his own nephew. It remains to be mentioned, that at the meeting of parliament, in which these noblemen were impeached, all the acts in which Gloucester had taken a share were annulled, the commission of government was cancelled, the opinions of the judges were declared to be legal, and the judgment against Michael de la Pole was reversed. History. 1399.

After the destruction of Gloucester and the heads of his party, a misunderstanding arose amongst the noblemen who had joined in the prosecution. The Duke of Hereford, son to John of Gaunt, appeared in parliament, and accused the Duke of Norfolk of having uttered treason in a private conversation. Norfolk denied the charge, and offered to establish his innocence by single combat. The challenge was accepted; but the king interrupted the duel, and commanded both the parties to leave the kingdom. The Duke of Norfolk was banished for life, but the Duke of Hereford only for ten years. The former retired to Venice, where he died shortly afterwards. Hereford displayed so much resignation to the will of his sovereign, that the latter commuted the period of his exile to four years. The king had obtained the object of his wishes, namely, the civil destruction of those whose power he dreaded. Even his uncles, either through affection or fear, seconded all his measures, which were now deeply tainted with despotism. On the death of John of Gaunt, "time-honoured Lancaster," the crown claimed his immense estates, to the exclusion of the banished Earl of Hereford, who was pronounced incapable of inheriting them after the judgment which had been pronounced against him in parliament.

By these and other impolitic acts, the king overstrained the bow, and excited a spirit of discontent, which finally hurled him from the throne. The resentment of Hereford had been inflamed by the injury which he had received, and he only waited for a favourable opportunity of retaliation, which soon afterwards occurred.

The Earl of March, presumptive heir to the crown, having been appointed the king's lieutenant in Ireland, was slain in a skirmish with the natives of that country; and Richard, regardless of his precarious situation at home, went over to Ireland with a considerable army, in order to revenge the death of his relative. Hereford, now duke of Lancaster, took advantage of the king's absence. Solicited by the discontented lords, and aware of the alienation of the people from Richard, he embarked at Nantes, and, with a retinue of only sixty persons in three small vessels, landed at Ravenspur in Yorkshire. The Earl of Northumberland, who had long been a malcontent, together with Henry Percy, his son, surnamed *Hotspur* on account of his impetuous valour, immediately joined him with their forces; and the people flocked to him in such numbers that in a few days he found himself at the head of sixty thousand men.

Richard in the mean time continued in fancied security in Ireland. Adverse winds for three perilous weeks together prevented his receiving any news of the rebellion which had broken out in his native dominions; but when the intelligence arrived he was overwhelmed with dismay. Some advised him to sail immediately and face the danger; others recommended that he should first send over the Earl of Salisbury, for the purpose of collecting all who were disposed to support his interests, which plan was adopted. A numerous army joined the earl, but the king protracted his stay in Ireland so long, that on his arrival the whole of this force had melted down to less than an hundred men. To take the field against Henry of Lancaster was consequently out of the question. He therefore proceeded in disguise to the fortress of Conway, where

History. 1399.

Salisbury had taken up his quarters. It was the policy of Henry to show symptoms of negotiation, in order to allure the king into his own hands. This he effected in a very deceitful manner. The Earl of Northumberland was dispatched to Richard with a thousand men, who concealed themselves at some distance, whilst the earl proceeded to the fortress where the king was lodged, and by fair promises induced him to quit his stronghold and go along with him to Henry for the purpose of effecting a reconciliation. But during the journey Richard was made prisoner, and finally committed to the Tower to await the judgment of parliament. On Monday the 29th of September 1399, a deputation of lords and commons waited upon the king, and having reminded him of a declaration which he had formerly made at Conway Castle, of his unfitness to govern, and readiness to resign the crown, required his resignation of the regal power. To this he consented, according to the ancient chroniclers, "with a cheerful countenance." During his whole reign, Richard held the sceptre with a wavering grasp, and in the paralysis with which he was now stricken, he as it were unconsciously relinquished it. He likewise recommended Henry his nephew as a fitting successor to the throne.

Before proceeding with the reign of Henry IV. we shall follow the deposed monarch through the few sad weeks of his unhappy life. By parliament he was adjudged "to a perpetual prison, to remain there *secretly* in safe custody." Richard was accordingly consigned to close confinement, and shortly afterwards came to his end, there can be little doubt in an unnatural manner. His fate seems to have been accelerated by a conspiracy amongst his friends to restore him to the throne. The Earls of Kent, Huntingdon, and Salisbury, laid a plot for the destruction of King Henry; but the secret was betrayed, and the confederated noblemen were executed. The death of Richard seems to have immediately followed this unsuccessful enterprise, but the manner of it is involved in impenetrable mystery. According to some chroniclers, several ruffians were sent to the castle of Pomfret, where he had been removed, for the purpose of dispatching him. They rushed unexpectedly into his apartment; but he succeeded in wresting a pole-axe from one of the murderers, with which he killed several of them, but was at length overpowered and slain. Others relate that he was starved in prison, and that he lingered fifteen days before he expired.[1] According to some accounts, he was condemned to suffer this miserable and protracted death; whilst others state that it was a voluntary abstinence, to which he was impelled by despair. He died in the thirty-fourth year of his age, and twenty-third of his reign. It was during the life of Richard II. that Wickliff, the celebrated reformer, promulgated his doctrines in England. See WICKLIFF.

After the throne had been vacated by its legitimate occupant, Henry duke of Lancaster stepped forward and claimed it in right of his being a descendant of Henry III. He was descended from this monarch both by father and mother, but he could not claim by the father's side, because the young Earl of March was sprung from the Duke of Clarence, the elder brother of John of Gaunt, nor by the mother's side, because she was sprung from Edmund of Lancaster, a younger brother of Edward I. It was pretended that Edmund was the elder brother, but it was never proved. By the law of succession it belonged to the descendants of Lionel, the third son of Edward III. That prince died without issue male, and his possessions and pretensions descended to his daughter Philippa, wife of Roger Mortimer, the male representative of the powerful baron who was attainted and executed for the murder of Edward II. the grandfather of the Duke of Clarence. The son of that powerful delinquent had been restored to his honours and estates at a late period of the reign of Edward III. The fourth in descent from the regicide was Roger Mortimer, lord-lieutenant of Ireland, who was looked upon as heir to the crown during the early part of Richard's reign; but his son Edmund Mortimer was only ten years of age when Richard was deposed, so that his claim was easily set aside. Mortimer died in 1425 without male issue, and the pretensions which he inherited through the Duke of Clarence fell to his sister Anne Mortimer, who espoused Richard of York, earl of Cambridge, the grandson of Edward III. by his fourth son Edmund of Langley, duke of York. But from the foregoing pedigree it is clear that during the life of the Earl of March no right to the crown had descended to any branch of the house of York. Henry, however, notwithstanding the inferiority of his title, was unanimously acknowledged by both houses, and was crowned within a fortnight after the deposition of his predecessor. He was the idol of the populace, the master of parliament, and the heir of the fame and possessions of John of Gaunt.

History. 1402.

The reign of Henry IV. was little else than a continued series of insurrections. In the very first parliament which he assembled, a great number of challenges were given and accepted by different barons; and though Henry had ability and address enough to prevent these duels, it was not in his power to avoid continual combinations and revolts against himself.

The most formidable of these disorders was that under the Earl of Northumberland. Various causes are assigned for this insurrection. One is, that the resentment of the Percies had been excited by the king denying them the privilege to liberate or ransom their prisoners; for at the battle of Homildon, where the Scotch suffered a defeat, a number of noblemen had fallen into the hands of Hotspur, who commanded the English. The insurgents themselves assigned another cause for the quarrel, and this was probably the real one. In the course of a war with the Welsh, the Lord Grey of Ruthyn and Sir Edmund Mortimer had both fallen into the enemy's hands. The former being a friend to the king, was allowed to be ransomed by his relations; but the latter, who was uncle to the young Earl of March, the lawful heir to the throne, and of course an object of jealousy to Henry, was denied the privilege of being liberated. This fired with resentment the inflammable spirit of Hotspur, who had married the sister of Sir Edmund; his father the Earl of Northumberland, and his uncle the Earl of Worcester, shared his discontent; and amongst them they projected nothing less than the dethronement of the king.

With this view they formed an alliance with the Scots and Welsh, who were to make an irruption into England, at the same time that the Percies were to raise what forces they could in order to join them. The Earl of Northumberland, by a sudden fit of illness, having been incapa-

[1] It was at first believed that Richard had effected his escape into Scotland, and that he lived there twenty years. This ancient tradition has been revived by Mr Tytler, in his *History of Scotland*, and he supports his views with considerable ingenuity. The chief evidence upon which he relies consists in charges made by the regent of Scotland for the expenses of the king of England. But Sir James Mackintosh, in a note at the end of the first volume of his *History of England*, gives several cogent, and we think unanswerable reasons for differing from Mr Tytler upon this point, and adhering to the common narrative. Those who feel an interest in this subject are referred to the work above mentioned, and to the appendix to the third volume of Mr Tytler's *History of Scotland*.

History.
1403.

citated for active warfare, young Percy took the command, and marched to Shrewsbury for the purpose of joining the Welsh. But the king had assembled a small army, with which it was his intention to act against the Scots; and, knowing the importance of celerity in civil wars, instantly hurried to meet the rebels. He approached Shrewsbury before a junction could be effected with the Welsh; and by his headstrong impatience Percy was impelled to risk an engagement, which at that time he ought to have declined. The evening before the battle he sent a manifesto to Henry, in which he renounced his allegiance, set the king at defiance, and enumerated all the grievances of which he imagined the nation might justly complain. Amongst the charges with which he reproached the king, were those of perjury, murder, and usurpation of rightful property. All this vituperation was productive of no other effect than that of exasperating to the utmost both the king and his adherents.

The armies were fairly matched, consisting of about fourteen thousand men each, and both leaders were men of approved valour. The action, which took place on the 21st of July 1403, was obstinate and bloody. After a chivalrous display of his characteristic valour, Percy was slain by a random arrow, and with his fall the courage and the confidence of his followers evaporated. They were completely routed, and driven from the field with great loss. Lord Worcester and two other conspicuous individuals were beheaded on the field. The Earl of Northumberand, however, notwithstanding his connection with the rebels, was mercifully treated by Henry. But this lenity does not appear to have quieted the country; for various insurrections, particularly amongst the Welsh under the celebrated Owen Glendower, disturbed the remaining years of Henry's reign. Owen, under the title of Prince of Wales, gained so many remarkable successes over the royal troops, that the king himself publicly attributed them to necromancy. The unconquerable spirit of the Welsh leader actuated all classes of his countrymen, who flocked to his standard from every part in England where they had taken up their abode. Owen remained free and unsubmissive to the English yoke till the close of his career, and the last glimpse which history affords of his patriotic course is as bright as the first.

The reign of Henry was much disturbed, and the language which our great dramatist makes him employ, "uneasy lies the head that wears a crown," is remarkably appropriate from the lips of such a monarch. The swell with which the nation heaved when he ascended the throne never subsided during his lifetime. The position in which he stood with regard to the succession seems to have caused him much concern; for the case was a difficult one. In his first parliament his eldest son Henry was created Prince of Wales; and in 1404 the right of that prince's brothers to reign, in the event of his dying without issue, was recognised by parliament. The most disgraceful feature of Henry's reign was his deadly persecution of those who entertained the new religious doctrines. In his second year was passed that sanguinary act, the first that stains the English statute-book on the subject, which orders heretics to be burned; and many an unfortunate Lollard suffered for his faith during the sway of the Bolingbrokes. A remarkable circumstance occurred in 1405, namely, the capital punishment of a clergyman of the highest rank. Scroop, archbishop of York, was an enthusiastic defender of the claims of the Earl of March, and, being taken in arms against his sovereign, was beheaded without trial, conviction, or defence.

Notwithstanding the act against the Lollards, the doctrines of Wickliff gained ground; and the support which Henry gave the hierarchy did not preclude his parliament from attempting its reformation, and even from despoiling it of part of its possessions.

History.
1413.

In 1405 the Commons, who had been required to grant supplies, proposed to the king to seize all the temporalities of the church, and employ them as a perpetual fund to meet the exigencies of the state. When this address was presented, the Archbishop of Canterbury, who then attended the king, objected that the clergy, though they went not in person to the wars, sent their vassals and tenants in all cases of necessity; whilst at the same time they themselves who staid at home were employed night and day in offering up their supplications for the success of the enterprise and the prosperity of the state. The speaker answered with a sarcastic smile, that he thought the prayers of the church but a very slender supply. The archbishop, however, prevailed in the dispute; the king discouraged the application of the Commons, and the Lords rejected the bill which the lower house had framed. The Commons were not discouraged by this repulse; in 1410 they returned to the charge with renewed zeal and determination.

A Lollard had been burnt, and the lower house of parliament, as if in retaliation of this atrocity, presented a schedule to the king, showing that he might have from the temporal possessions of the bishops, abbots, and priors, that were then uselessly wasted, 15 earls, 1500 knights, and 6200 esquires. But the reply of the king was severe, and he forbade them to discuss such topics for the future. They then petitioned that the clergy should be subjected to the civil tribunals, but this was also refused; and a request that the statute against the Lollards might be mitigated shared the same fate.

The reign of Henry was now drawing towards a termination. The last years of his life were darkened by disease, and undistinguished by vigour. He had been subject to eruptions in his face and to attacks of epilepsy. By one of these he was carried off, at Westminster, on the 20th of March 1413, in the forty-seventh year of his age and fourteenth of his reign. Henry owed the English sceptre, not, in the first instance, to his own plotting or ambition, but to a popular revolution against the authority of his predecessor. He landed in England for the avowed purpose of only seizing his own possessions, of which he had been most unwarrantably deprived; but finding Richard a most unpopular sovereign, and his own reputation very high, whilst his affinity to the blood royal was, though not so near as that of the Earl of March, sufficiently so to give him a plausible pretext for standing forward as a candidate for the crown, he accordingly did so, and proved successful. He united in a high degree watchfulness and circumspection, with a bold and decisive policy. For his arbitrary measures he brought forward the plea of necessity, "which," says Sir James Mackintosh, "prevented them from growing into precedents subversive of the constitution." As he owed his throne to popular revolt, so he was in some measure compelled to adopt popular principles. Under his reign the House of Commons advanced with a steady pace towards importance and authority. It assumed a higher and more decisive tone than had hitherto characterized its proceedings, and pushed its inquiries into all the affairs and departments of government.

Henry of Monmouth, eldest son of the preceding monarch, ascended the throne immediately after the death of his father. With the early life of Henry V. we usually associate acts of frivolity, insubordination, and even low vice. But to the creative genius of a powerful poet must in a great measure be attributed this almost universal impression. That he was guilty of delinquencies beneath the dignity of the heir apparent to the English throne, may be true; but there is no satisfactory evidence

History. 1413.

either to confirm or refute the traditionary stories which are told of him. At an early age he discovered talents of no common order. He was only sixteen years of age when the battle of Shrewsbury was fought, and on that occasion he displayed equal firmness and ability. Afterwards, when intrusted with the guardianship of the Welsh marches, he conducted himself in a manner so highly creditable, that he more than once received the thanks of the House of Commons for his conduct. On his accession to the throne, he made himself popular by several wise and generous measures. He liberated his cousin the Earl of March from the constraint under which that prince, undoubtedly the heir of Edward III., had been held by the jealousy of Henry IV. The Percies, who were exiles in Scotland, he restored to their possessions, and even to a command over their martial vassals. Those ministers of his father who had recommended themselves by their uprightness and decision, were retained in the offices which they held. The chief justice, in particular, who had formerly imprisoned the king, whilst Prince of Wales, for his misconduct, was not only pardoned, but received into high favour. He expressed deep regret for the fate of Richard II., and performed his funeral obsequies with becoming pomp and solemnity. That Henry had a mind which towered above the level of his contemporaries, his remarkable triumphs in France are evidence: but that in some respects he was not in advance of his age, the severities which he practised against the Lollards afford ample proof. The head of that party was Sir John Oldcastle, an individual alike distinguished for his valour and military talents, and who had acquired the esteem both of the late and present king. His high character pointed him out as a proper object of ecclesiastical fury, and he was accordingly denounced to Henry, who, at a private interview, attempted to make him recant his faith; but in vain. Oldcastle was therefore condemned to suffer the death of a heretic; but having effected his escape, he raised an insurrection, which was soon crushed. He succeeded however in eluding pursuit for four years, but he was at last taken and executed as a traitor. After the suppression of the revolt, the most severe laws were passed against the unfortunate Lollards. It was enacted, that whoever should be convicted of Lollardy, besides suffering capital punishment according to the laws formerly established, would also forfeit his lands and goods to the king; and the officers of government were likewise bound by oath to use their utmost endeavours to extirpate the heresy.

The restoration of tranquillity afforded Henry an opportunity of turning his attention to France, the miserable condition of which offered a fair prospect of success to his arms. The claim of his family to the crown of that country was revived; and on the 15th of April 1415 he assembled a great council at Westminster, to whom he announced his determination of making a "voyage in his own proper person, by the grace of God, to recover his inheritance." He appointed his brother, the Duke of Bedford, lord lieutenant of the kingdom during his absence. When about to set sail for Normandy, a rash conspiracy broke out, which detained him for a little time; but it was soon suppressed, and Henry embarked at Southampton with an army of about thirty thousand men, the greater proportion of whom were archers. He entered the Seine, and having reduced Harfleur, he challenged the dauphin to meet him in single combat, and decide the contest for the crown of the country which he had invaded. But this was destined to be competed for on a far wider arena than that which two combatants could occupy. Henry crossed the Somme, and was proceeding on his road towards Calais, when he came up with the enemy at a small village, called by the French Azincourt, and by the English Agincourt. Here was fought a great and decisive battle, which ended in the total defeat of the French army, estimated at not less than four times the strength of that of the English. (See Agincourt.) Henry did not immediately pursue his victory, and returned to England, where he was received with the utmost enthusiasm; but he soon afterwards rejoined his troops in France. The claimants for the crown of that kingdom were so numerous, that had he boldly prosecuted his own schemes, the opposing factions might have leagued together against him as a common enemy. It was therefore his policy to remain inactive, and, by tampering with them separately, to foment the discord which prevailed amongst the French leaders. On the 21st of May 1420, a treaty was at length concluded at Troyes, which promised to crown the hopes of the Plantagenets with success, and establish them on the throne of France. The principal articles stipulated the marriage of Henry with Catherine, daughter of the French king; that Henry should be regent of France whilst Charles remained alive; and that he should succeed that monarch after his decease. Henry accordingly espoused the French princess; but he was not long permitted to enjoy his connubial happiness or his good fortune. A fatal malady seized him at Paris; and having been conducted by his own orders to Vincennes, he expired there on the 31st of August 1422, in the thirty-fourth year of his age, and the tenth of his reign.

History. 1422.

The name of Henry V. is adorned with all the splendour of brilliant conquest and successful ambition. By a single victory he brought the crown of France within his reach, if not within his grasp. But he had other qualities besides those of a warrior; he was a statesman of consummate skill, as his conduct after the victory of Agincourt sufficiently testifies. His mind was altogether of a superior order, and there seems nothing to prevent his being ranked with the greatest of English monarchs, except the countenance which he gave to ecclesiastical persecutions.

By Catherine of France Henry had a son who succeeded him when not yet a year old. The whole of his long reign is occupied with a war for the French crown, and a disastrous civil war in England between the houses of York and Lancaster. At the accession of Henry VI. parliament ordered a new royal title, in which he was recognized as king of France and England, and lord of Ireland; appointed his father's eldest brother, the Duke of Bedford, protector, defender, and chief counsellor of the kingdom and of the English church; and in his absence invested the Duke of Gloucester, his younger brother, with these honours. A council was named, and certain articles enacted, for the purpose of limiting the power of the protector. The kingdom of France was now in the most deplorable situation. By the solemn investiture of the infant king of England with the royal prerogative in that country, Charles VII. succeeded only to a nominal kingdom; for the greater portion of it adhered to the interests of Henry. But notwithstanding all these advantages, the English daily lost ground, and in the year 1450 they were finally expelled from the country. See the article France.

It may be easily conceived that such a train of bad success was likely to be productive of discontent at home. Continual animosities were kept up amongst the king's counsellors during the first thirty years of his nominal rule. This tended to plunge the nation in convulsions, and prepare it for becoming the theatre of a sanguinary civil war. Humphrey duke of Gloucester was envied by many on account of his high station. Amongst these was Thomas Beaufort, bishop of Winchester, afterwards cardinal, the legitimate son of John of Gaunt, brother to

History. 1424.

Richard II. This prelate, to whom the care of the king's education had been committed, was a man of some capacity and experience, but of an intriguing and restless disposition. He had frequent disputes with the Duke of Gloucester, over whom he gained several advantages. The Duke of Bedford employed both his own authority and that of parliament to reconcile them, but in vain; their mutual animosities served for several years to embarrass government, and to lay it open to its enemies. The sentiments of the two leaders were particularly divided with regard to France. The bishop laid hold of every prospect of accommodation with that country; and the Duke of Gloucester was for maintaining the honour of the English arms, and regaining whatever had been lost by defeat or delay. Both parties, therefore, called in all the auxiliaries they could command. The bishop resolved to strengthen himself by procuring a proper match for Henry, at that time twenty-three years of age, and then by bringing over the queen to his interests. Accordingly, the Earl of Suffolk, a nobleman whom he knew to be stedfast in attachment to him, was sent over to France, apparently to settle the terms of a truce which had then been contemplated, but in reality to procure a suitable consort for the young king.

The bishop and his friends had turned their attention to Margaret of Anjou, daughter of Regnier, titular king of Sicily, Naples, and Jerusalem, but who was destitute of either real power or possessions. She was looked upon as the most accomplished princess of the age, both in mind and person; and it was thought the abilities which she possessed would supply the want of them in her husband, to whom maturity of years had brought no maturity of understanding. He was a child from the cradle to the grave. The treaty was therefore hastened on by Suffolk, and soon afterwards ratified in England. Previously to the king's marriage, however, a conspicuous blow was struck at the protector's greatness. In that age a charge of sorcery was capable of blasting any character, however spotless or pure; and even of throwing odium upon all who were related to the individual accused. It was an irresistible weapon made use of by churchmen for the destruction of their enemies, and it was wielded by the prelate against his political opponent with tremendous force. He brought forward an accusation of sorcery and treason against Elinor Cobham, wife or concubine of the Duke of Gloucester. She was charged with having made an image of the king in wax, which being placed before a gentle fire, gradually dissolved; and it was expected that as the wax wasted away, the strength of the king would also disappear, and that his death would take place when the whole of the image had melted. Three other individuals were implicated in this accusation, which was readily believed. The prisoners were pronounced guilty; the duchess was condemned to do penance and suffer perpetual imprisonment; one priest was hanged, and another died in prison; whilst, to consummate the affair, Margaret Jourdemayn, a reputed witch, was burnt at Smithfield.

The Bishop of Winchester was resolved to carry his resentment against Gloucester to the utmost. He procured a parliament to be summoned, not at London, which was too well affected towards the duke, but at St Edmundsbury, where the prelate's adherents greatly preponderated. As soon as Gloucester appeared, he was accused of treason, and thrown into prison. On the day appointed for him to make his defence, he was found dead in his bed, though without any signs of violence upon his body. This, however, is no proof that he came not by a violent end.

The death of the Duke of Gloucester was universally ascribed to the cardinal of Winchester, who himself died six weeks thereafter, without leaving behind him so good a name as his political adversary. The Lancasterian party was thus deprived of its chiefs: no male Plantagenet of that lineage remained except the king, who was at best but an apology for one.

History. 1449.

After the demise of the cardinal of Winchester, Suffolk governed with uncontrolled sway. But his conduct was obnoxious to the rest of the nobility, who now concerted measures for his destruction. In the year 1447 he was impeached of high treason on various charges. He was accused of exciting the French to invade England, in order to depose Henry and place on the throne De la Pole's son, who was to marry Somerset's daughter, considered by the Lancasterian party as the next in succession to the crown. He was also charged with the loss of France by his negotiations in that country, and with revealing state secrets to the French ministers. Other illegal acts were ascribed to him in the bill of impeachment; and so strong did the current of opinion run against him, that, whether guilty or not, the king was compelled to banish him from the kingdom. But this did not satisfy his enemies, who looked upon expatriation as a sheltering from justice rather than as a punishment. The captain of a ship was therefore employed to intercept him in his passage to France; and, having been seized near Dover, his head was struck off in a small boat, and his body consigned to the waves.

The complaints against Henry's government were heightened by an insurrection, headed by an individual of equivocal descent, but who has been transmitted to posterity by the name or nickname of Jack Cade. He assumed the honourable name of John Mortimer; and having assembled a great body of the peasantry of Kent, he marched to Blackheath. A message was sent to him by the king, demanding the cause of the insurrection. The audacious Cade answered in the name of the community, that their purpose was to punish evil counsellors, and to obtain a redress of grievances. Henry assembled a force; but part of it having been defeated, the remainder refused to fight, and the king retired from the field. Lord Say, the treasurer, was committed to the Tower, in order to satisfy the revolters. In the mean time, the citizens of London opened their gates to the victorious rebel, who made a triumphant entry into the city arrayed in the shining armour and gilt spurs of a knight. For some time he maintained great order and regularity amongst his troops. He always led them out into the fields in the night-time, and published several edicts against every kind of plunder and violence. His followers, however, were not to be thus restrained. Lord Say, without any trial, was beheaded; and soon afterwards, the insurgents, having committed some irregularities, were shut out of the city by the inhabitants. Cade endeavoured to force his way back to his quarters, when a bloody scuffle ensued, which was only terminated by the approach of night. The Archbishop of Canterbury, and the chancellor, who had taken refuge in the Tower, hearing how matters stood, drew up an act of amnesty, which was privately circulated amongst the rebels. This had an electrical effect upon them, and in the morning Cade found himself totally abandoned by his followers. He effected his escape, but was afterwards captured and slain. A number of circumstances now contributed to revive the long dormant pretensions of the house of York to the throne. France had been lost; the arms of England had been disgraced; Margaret the queen, by violence and arrogance, was most unpopular; the king himself was a perfect cipher; whilst, in strong contrast to him, appeared the Duke of York, a man of popular virtues, and the legitimate heir to regal power, according to the English laws of real inheritance. All the males of the house of Mortimer were now extinct; but Anne, the sister of the last Earl of March, having

History. 1449.

espoused the Earl of Cambridge, who had been beheaded for treason in the reign of Henry V. had transmitted her latent but unforgotten claim to her son Richard. This prince, descended by his mother from Philippa, only daughter of the Duke of Clarence, third son of Edward III. stood plainly in order of succession before the king, who derived his descent from the Duke of Lancaster, fourth son of that monarch. The duke was a man of valour and abilities, as well as of some ambition; and he thought that the weakness and unpopularity of the present reign afforded a favourable opportunity for asserting his title. The ensign of Richard was a white rose, and that of Henry a red one; circumstances which gave names to the two factions who were now about to deluge the kingdom in blood.

The Duke of York was in Ireland during the proceedings against Suffolk and the sedition of Cade. In September 1450 he returned to England, a circumstance which excited considerable alarm at court. He advanced upon London; and, proceeding to the palace at Westminster, knelt before the king, and, deploring the state of the kingdom, entreated him to summon a parliament. The queen appears to have evinced her usual arrogance upon this occasion; but York succeeded in extorting a promise from the king that he would comply with his request, upon which he retired to his castle at Fotheringay. He was scarcely gone, however, when the Duke of Somerset returned from France, and was chosen favourite adviser of the king. The session of parliament proved unquiet and stormy. York presented a complaint against the administration of Somerset, and in the year following exhibited several articles of impeachment against him. But the power and influence of the queen rendered his efforts fruitless. Legal prosecutions became thus inadequate to suit the feelings of the enraged York, and he accordingly assembled an army. The king, doubting his ability to triumph by opposing force to force, affected to acquiesce in the demands of the duke, and put Somerset under restraint. Upon this York disbanded his troops, and retired unattended to the royal pavilion, where he was immediately made prisoner, and compelled to take an oath of allegiance to the king. Somerset rose higher in favour than ever, and completed his ascendency in the government by obtaining the entire confidence of the king and his consort.

On the 13th of October 1453 Queen Margaret presented her husband with a son and heir, the ill-fated Edward prince of Wales. Not long afterwards the king sunk into a state of mental as well as bodily incapacity, and the star of York again appeared above the horizon. The total imbecility of the king having been ascertained, the Duke of York was chosen protector and defender of the kingdom. Previously to this event Somerset had been removed from the palace of the queen to the Tower. The king's malady was not permanent, and on his recovery he put an end to the protectorate, released Somerset from his confinement, and reinstated him in his honours. This was a mortal blow to the peace of York; and having conferred with the powerful Earls of Warwick and Salisbury, who united themselves to his interests, he took the field with the declared intention of only expelling Somerset from the government. But this nobleman's fate involved that of the house of Lancaster. It was in vain that the king attempted a reconciliation of interests; he was compelled to have recourse to arms, and meet the Yorkists in open warfare. A battle took place at St Albans, in which the royalists were totally defeated; Somerset, the immediate cause of the conflict, having fallen in the action.

The king relapsed into his former state, and the Duke of York was a second time chosen protector; but the queen, who could not brook the idea of his continuing at the head of government, procured his dismissal. She is even charged with having conspired his destruction, and that of his most conspicuous adherents. A temporary reconciliation was effected, but discord was again introduced; and the parties having irrecoverably lost confidence in each other, prepared for the deadly struggle of arms.

History. 1460.

The forces of the Duke of York under the Earl of Salisbury gained an advantage over the royalists at Bloreheath; but a fatal desertion on the part of York's troops at Ludlow turned the balance in favour of the king; and York fled to Ireland, where he was joyfully received.

But this disaster, though in appearance it suppressed the party of York, was far from being fatal to its power. The snake was scotched, not killed, and it only waited a favourable opportunity for darting on its victim. This soon presented itself. Warwick, who had retained the government of Calais, landed in Kent, and, being joined by a number of barons, advanced upon the capital, which he entered amidst the acclamations of the people. The number of his troops had now so much increased that he found himself in a condition to encounter the royal army. Early in July 1460 he came up with them at Southampton, and a bloody battle ensued, in which the king was taken prisoner, and his army utterly dispersed. Meanwhile the Duke of York having returned from Ireland, openly laid claim to the crown. In the House of Lords the cause of Henry and the Duke of York was solemnly debated; and the latter, though a conqueror, did not absolutely gain his cause. It was determined that Henry should possess the throne during his life, and that the Duke of York should be appointed his successor, to the utter exclusion of Henry's offspring.

Though the royal party now seemed destitute of every resource, the queen still retained her intrepidity, disdaining every arrangement which implied the dethronement of her child. Wales seemed the natural place of refuge for the mother of him who was called its prince, and thither accordingly she fled. This warlike dame assembled a considerable army to rescue her pusillanimous husband, and marched to the northern provinces, where Northumberland and Clifford joined her with their borderers. This union having alarmed the victorious party, York and Somerset hastened to anticipate their designs, and, having assembled a sufficient force, succeeded in reaching the strong castle of Sandal before Christmas. Actuated by the pride of prowess and the impatience of inaction, York engaged the queen's army with one of inferior force. The conflict took place at Wakefield on the 30th of December 1460, and terminated in the total defeat of the Yorkists. The duke himself was either slain in the action, or put to death after it; whilst the Earl of Salisbury was taken during the night, and decapitated next day. But no one was so much lamented as the young Earl of Rutland, the son of York, a boy in the twelfth year of his age. He was made prisoner, and coolly stabbed to the heart by Clifford, in revenge for the death of his father, who had perished at the battle of St Albans.

After this victory Margaret marched towards London, in order to set the king at liberty; but the Earl of Warwick, who had now put himself at the head of the Yorkists, led about the captive king in order to give a sanction to his proceedings. Except by the countenance which his presence seemed to give to the transactions of the Yorkists, he was as inert an instrument in their hands as the royal standard which waved above their lines. Warwick engaged the queen's forces at St Albans; but, through the treachery of Lord Lovelace, who deserted with a considerable force during the heat of the action, Warwick was defeated, and the pageant king fell once more into the hands of his own party.

History. 1460. The submission of the city of London seemed now to be all that was wanting to complete the queen's success; but Warwick had secured it in his interests, and the citizens refused to open their gates to the royal victor. In the mean time, young Edward, eldest son of the late Duke of York, put himself at the head of his father's party. He was now in the bloom of youth, remarkable for the beauty of his person and for bravery; and he was, moreover, a very great favourite with the people. He defeated Jasper Tudor, earl of Pembroke, at Mortimer's Cross in Herefordshire; the earl himself being taken prisoner, and immediately beheaded by Edward's orders.

Meanwhile he was joined by the remainder of Warwick's army, and the united forces entered the metropolis amidst the applause of the people of the city and of the surrounding provinces. Edward laid his claim before a council of lords, and on the 4th of March 1461 he was proclaimed king by the style and title of Edward IV.

But notwithstanding all her disasters, the queen remained inflexibly devoted to her purpose. She retired to the northern counties, where such numbers flocked to her standard that her army very soon amounted to sixty thousand men. Edward IV. was a voluptuary, but he never allowed his activity and vigilance to slacken. With Warwick and an army of forty thousand men he commenced his march to the north. The hostile forces met at Towton, in the county of York, on the 29th of March 1461, and an obstinate engagement ensued, which continued during the night, and was renewed with the utmost fierceness on the following morning. The queen's army was totally defeated, and, as quarter was given on neither side, the slaughter was dreadful. Between thirty and forty thousand persons perished in these two bloody days. After this disaster the queen with her husband took refuge in Scotland, whilst Edward returned to the metropolis, where he was crowned on the 29th of June 1461. For three years Edward IV. possessed the throne without any serious insurrection having taken place on the part of the Lancasterians. But during this period Queen Margaret was making strenuous exertions both in France and Scotland to raise a force capable of taking the field against Edward. Having collected a small army, she made an inroad into England, but after several indecisive skirmishes she was totally defeated at Hexham, in Northumberland, on the 17th of May 1464. The Duke of Somerset, who commanded for her, was beheaded; and a number of gentlemen were also executed at York, with little form of law or justice.

By these repeated misfortunes the house of Lancaster became so effectually reduced that Margaret was obliged to separate from her husband, and both were compelled to seek their safety in individual flight. The king was still protected by some of his friends, who conveyed him to Lancashire, where he was at last discovered, and consigned to the Tower as a prisoner. The queen made her escape through Scotland into France, along with her son, and his famous preceptor Sir John Fortescue.

In the mean time King Edward vigorously applied himself to the affairs of government. Feeling secure on the throne, he now also began to give way to the gratification of his amatory passions, to which he was exceedingly prone. In order to divert his mind from such debasing indulgences, the Earl of Warwick, hitherto his steady friend, advised him to marry. Edward consented, and the earl was appointed to negotiate a match with the Princess Bonne of Savoy. He was successful in his mission, but before the conclusion of the marriage treaty the king privately espoused a lady of whom he had become enamoured, and who resisted all his efforts to form an illicit connexion. This lady was Elizabeth, daughter of Sir Philip Woodville, and relict of Sir John Grey, a Lancasterian, who had fallen at the second battle of St Albans. The parties were solemnly united in marriage on the 1st of May 1464, and the bride was acknowledged and in due time crowned. This transaction highly displeased Warwick, who afterwards became still more disgusted at the favour shown to the queen's party, his own and his sovereign's natural enemies. A plan of revenge was therefore set on foot, and a most powerful conspiracy was also formed against Edward. To accomplish his aim, Warwick not only employed his own influence, which was very extensive, but likewise that of the Duke of Clarence, Edward's brother, on whom the earl had conferred the hand of his daughter without the king's permission. The effects of Warwick's secret combination with Clarence, his own brother Montague, and the discontented nobility and gentry, soon began to appear. Sedition was fomented throughout the country, and a popular insurrection at last broke out in Yorkshire, where Robin of Redesdale, a hero amongst the moss troopers of the border, appeared at the head of sixty thousand men. The articles of their manifesto were principally directed against the king's counsellors and the church.

History. 1469. Henry earl of Pembroke was sent against them with a body of seven or eight thousand men. He was joined by Lord Stafford with five thousand more troops, and the two commanders prepared to meet the insurgents. They at first received a repulse, but it was of no material importance. An unfortunate dispute, however, between Pembroke and Stafford, caused the latter to march off the field with his troops; and in a battle which immediately afterwards ensued, the royalists were cut to pieces, and their commander taken prisoner and beheaded.

The king, enraged at this, caused Stafford to be executed in a like summary manner. This event completed the disaffection of the king's followers, who now deserted him in thousands; and he himself was at last taken prisoner by Warwick and his friends; but this conquest embarrassed the confederated nobles. The detention of the king was not popular; and the military refused to act until he was released, which took place accordingly, and a reconciliation was effected. The truce was, however, of short duration. A new insurrection broke out in Lincolnshire, in which Warwick and Clarence were deeply involved. The rebels were commanded by Sir Robert Welles, son to a nobleman of the same name. Under an alleged charge of treason, the latter was beheaded by the king, who marched against the insurgents with his usual celerity, and gave them a total overthrow at Erpingham, in Rutlandshire, on the 12th of March 1469. Warwick and Clarence again attempted to entrap Edward, but having failed of success, they escaped to France.

Louis XI. openly espoused the cause of the malcontent barons, and effected a reconciliation between them and the fugitive Queen Margaret. Their mortal enmities were reconciled in common hatred of the king of England. A treaty was concluded, which stipulated that Edward should espouse Anne Neville, Warwick's daughter, and that they should combine their efforts to restore Henry to the throne of which he had been deprived. It was likewise agreed upon, that in case of failure of issue by the prince, the crown should descend to Clarence. After these preliminary arrangements, Warwick assembled a small force, and set sail for England, where he landed whilst Edward was in the north suppressing an insurrection which had there broken out. This seems to have been an artifice practised by a brother-in-law of Warwick's, who thus drew the incautious monarch to a distant part of the kingdom, and left the southern counties open to the invader. Warwick was a great favourite with the people, the subject of

History. 1469.

popular ballads, which resounded his praise throughout every town in the kingdom. Thousands having flocked to his standard, he advanced upon London, and there proclaimed Henry VI. The usual activity of Edward seems to have forsaken him, or else his pernicious frivolities had alienated the affections of his troops, whose fidelity towards him likewise decreased as Warwick drew near to them. Edward was compelled to fly to Holland, Clarence and Warwick made their triumphal entry into the capital, and Henry was formally restored to regal authority. But those who had reinstated him had placed only a barren sceptre in his grasp, for the real power resided with them. Edward was pronounced an usurper, and all acts passed under his sanction were repealed. The crown was settled on the male issue of Henry VI., and in default of such issue, on the Duke of Clarence and the heirs of his body. But Edward's party was not yet destroyed. After an absence of nine months, he, seconded by a small body of troops granted him by the Duke of Burgundy, made a descent at Ravenspur in Yorkshire. At first he met with little success; but his army increasing on his march, he was soon in a condition to appear before the capital, which instantly opened its gates to receive him.

The unfortunate Henry was thus again plucked from the throne; and the hopes of Warwick were almost totally blasted by the defection of Clarence, Edward's brother. He however advanced to within about ten miles of London, resolving to wait the approach of Edward, and took a position at Barnet, where, on the 14th of April 1471, a battle was fought, more remarkable for its consequences than for the number of the slain or the obstinacy of the combatants. Considering the animosity existing between the parties, the general slaughter was unusually small; but amongst the fallen were Warwick and his brother Montague; and the death of the first of these individuals was of far more importance to Edward than the victory which he had gained. It broke the charm which associated with his name the certainty of victory and success to the cause which he espoused. On account of the remarkable transactions in which he had been engaged, he received the appellation of "the king-maker." His death also destroyed the greatness of the house of Neville.

At this time the queen had just returned with her son from France, where she had been soliciting supplies. She had scarcely time to refresh herself from the fatigues of the voyage, when she received the fatal news of the death of Warwick, and the total destruction of his forces. All her resolution was unable to support her under this calamity, and she sunk to the ground in despair. Upon recovering herself, she took sanctuary in the Abbey of Beaulieu in Hampshire, where she still found friends ready to assist her. Tudor earl of Pembroke, Courtenay earl of Devonshire, the Lords Wenlock and St John, with some other men of rank, encouraged her yet to hope for success, and promised to stand by her to the last. On this assurance she resumed the undaunted bearing which was natural to her, and, advancing through the counties of Devon, Somerset, and Gloucester, collected a considerable army. The hostile forces came in sight of each other at Tewkesbury on the 14th of May 1471, where a battle was fought, which decided this sanguinary war. The queen's army was totally defeated; the Earl of Devonshire and Lord Wenlock were slain in the conflict; the Duke of Somerset, and about twenty other persons of distinction, who had taken shelter in a church, were surrounded, dragged forth, and immediately beheaded; about three thousand of their soldiers fell in battle, and the rest were entirely dispersed. Queen Margaret and her son were taken prisoners, and brought to the king, who asked the prince how he dared to invade his dominions. The youth replied that he came hither to claim his just inheritance; upon which Edward struck him on the face with his gauntlet. The Dukes of Clarence and Gloucester, Lord Hastings, and Sir Thomas Gray, taking this blow as a signal for further violence, hurried the prince into the next apartment, and there, it is said, dispatched him.[1] Margaret was thrown into the Tower along with her husband Henry, who there closed his unhappy career a few days afterwards. The Duke of Gloucester has been charged with his murder, but there is no proof of the fact.[2] Margaret was ransomed by the king of France in 1475, for fifty thousand crowns. She survived her deliverance about seven years, during which time she lived in France, withdrawn from the tumults of state.

History. 1483.

Edward being now freed from all his enemies, began to inflict punishment on those who had formerly appeared against him. Amongst the cruelties which he committed, that on his brother the Duke of Clarence was the most remarkable. They had been formally reconciled to each other; but this hollow truce to fraternal animosity was broken by a singular incident. Whilst the king was one day hunting in the park of one Burdett, a servant of the duke, he killed a white buck which was a great favourite of the owner. Burdett, concerned at the loss, broke into a transport of rage, and declared that he wished the horns of the deer were in the belly of the person who advised the king to that insult. For this exclamation Burdett was tried for his life, and executed at Tyburn. Clarence exclaimed against this sentence as iniquitous, for which he was attainted of treason, and charged with sorcery, in order to give to Burdett's expressions the dignity of necromantic imprecation. Sentence of death was pronounced against him; but the king having some repugnance to order the public execution of a brother, he was dispatched in private. There was a rumour prevalent at the time that he was drowned in a butt of malmsey wine, to which he is said to have been very partial; but there is no proof that his murder was effected in this manner.

The remainder of Edward IV.'s reign is unimportant. A war with France, which followed the civil wars in England, terminated in 1475 without being characterized by any memorable events. But the foolish idea of aggrandisement in France was still popular with the people, and Edward employed a considerable portion of the latter years of his reign in making apparent preparations for reviving the pretensions of his predecessors to the crown of that country. It does not appear, however, that he ever had any intention of carrying his threats into execution. Edward died on the 9th of April 1483, in the forty-second year of his age and twenty-first of his reign, calculating from the period of his first assuming the crown. In the character of Edward IV. we see a combination by no means singular of great and vicious qualities. As a commander he possessed decision, promptitude, daring, and valour, in a remarkable degree; in these respects indeed he surpassed all his competitors. But the laurels which he won in the field were stained by many cool-blooded atrocities, which altogether deprive the individual who perpe-

[1] Such is the account commonly given of the death of this scion of the house of Lancaster. It is worthy of remark, however, that the Harleian manuscript not only gives no sanction to this popular tale, but expressly declares that the prince was slain in the field.

[2] A reader of the present day who can calmly dispossess his mind of the poetical associations with which the subject is invested, will probably agree with a historian who has minutely investigated the subject, that Gloucester is to be exculpated from the charge of murder in this case. (See Turner's *History of England*, vol. ii. p. 375.)

History. 1483. trated them of any claim to real greatness. He was cruel and faithless, and no barrier was capable of restraining him from indulging in sensual gratifications. Besides five daughters, he left two sons; Edward prince of Wales, his successor, then in his twelfth year; and Richard duke of York, then in his eleventh year.

On the death of Edward IV. the kingdom was divided into new factions; and those of the queen's family, who, during the last reign, had come into power, were obnoxious to the old nobility, who looked upon them as upstarts and inferiors. The king had endeavoured to prevent these animosities proceeding to any extent, by desiring on his death-bed that his brother Richard duke of Gloucester should be entrusted with the regency; and he recommended peace and unanimity during the minority of his son. But the monarch was no sooner dead than the former resentment between the two parties burst forth with violence; and the Duke of Gloucester, to whom it is customary to attribute every bad quality, resolved to profit by their contentions. As soon as he learned the tidings of his brother's death, he proceeded to Ludlow Castle, where Prince Edward then was under the charge of Lord Rivers, his uncle by the mother's side. This nobleman was charged by Gloucester with having instilled into the mind of his young ward unfavourable opinions of the protector, and under this groundless accusation he was put into confinement, along with others of the Woodville family. Gloucester, with Buckingham, his noted accomplice, marched to London with Prince Edward, and the other young prince's person having also been secured, both of them were consigned to the Tower, under the specious pretext that they would there be safe from the machinations of their enemies. The coronation was postponed from the 4th of May till the 22d of June, so that the secret purposes of the protector began to be unveiled; and it would seem probable that Hastings and Stanley, the friends of the late king, began to show some misgivings as to the designs of Richard. At a council held in the Tower on the 13th of June 1483, Hastings was seized, and soon afterwards executed upon a log of timber, without any form of trial. Stanley and other obnoxious lords were thrown into various dungeons; and on the same day Earl Rivers and some others were executed at Pomfret Castle, on the most unjust pretences of treason.

The protector now considered himself as in a situation to lay claim to the throne. He used his utmost endeavours to inspire the people with a notion of the illegitimate birth of the late king, and that his children were not only illegitimate on this account, but also because their father had been secretly wedded to Elinor Butler previously to the solemnization of marriage between him and Elizabeth Woodville. Shaw, a popular preacher, was hired to harangue the people to this effect from St Paul's cross. The number of Edward's amours gave some plausibility to these rumours, and prepared the minds of the people for the usurpation of the crown by Richard. Two days afterwards Buckingham harangued the populace in much the same manner as Shaw; and on the 25th of June 1483, that nobleman presented Richard with a parchment purporting to be a declaration of the estates of parliament in favour of the protector, as the only legitimate prince of the house of York. Richard, with his usual dissimulation, evinced some hesitation upon the point; but on the following day he took possession of the crown, and from the 26th of June 1483 is accordingly dated the commencement of his reign.

The only obstacles which now interposed between Richard and the peaceful possession of the crown were his two nephews, whom he still kept in the Tower, for the sake of safety, as he miscalled their imprisonment. During a progress through the kingdom a confederacy was formed against him, and meetings were held, which had for their object the liberation of the princes. But this was unnecessary, as they had been privately dispatched by the king's orders. The manner of their death was kept a profound secret, and it is very doubtful if even yet we are acquainted with the real facts. The most probable account, however, is, that Richard having tampered in vain with Brackenbury, the governor of the Tower, to put them to death, found a ready instrument for the execution of his diabolical purpose in Sir James Tyrrel, his master of the horse. This individual, with two other ruffianly associates, having obtained access during the night to the apartment of the princes, smothered them as they lay asleep, and buried their bodies at the foot of the staircase.

History. 1484. Richard having thus secured himself on the throne, attempted to strengthen his interest by means of foreign alliances, and also by procuring the favour of the clergy at home; but he found his power threatened from a quarter where he least expected an attack. The Duke of Buckingham, who had been so instrumental in raising him to the throne, either thinking his services inadequately rewarded, or for some other causes which cannot now be ascertained, instigated a revolt against Richard. The horror with which the intelligence of the midnight murder in the Tower was received prepared the public mind for seconding the designs of Buckingham, who, with several other leading individuals in the kingdom, now declared for Henry, the young Earl of Richmond, in opposition to Richard. The earl, at this period an exile in Brittany, was considered as the chief of the Lancasterian party. His right to the crown by succession was, however, very equivocal; but the cruel behaviour of Richard inclined the people generally to favour his pretensions; and, in order to give an additional strength to his title, a match was projected between him and the Princess Elizabeth, the eldest daughter of Edward IV., which, by uniting the two rival families, would put an end to those dissensions which had so long distracted the kingdom and deluged it with kindred blood. Messengers were accordingly dispatched to give him information of the conspiracy, which fortunately escaped the usual vigilance of Richard; and, in about a fortnight afterwards, Richmond returned an answer, which was no sooner communicated to his friends than it reached the ears of the king. The latter immediately summoned his adherents to join him with their retainers at Leicester; and after proclaiming Buckingham a traitor, he marched against him at the head of his army. In the mean time storms interrupted the voyage of Henry; and the army of Buckingham, dispirited by broken bridges and impassable currents, broke up and dispersed. A price was set upon the head of Buckingham, who fled, but was betrayed into the hands of Richard, and immediately put to death.

Richard, now emboldened by his success, employed every means of confirming his title to the throne, and destroying the plans of the exiles and malcontents. He summoned a parliament, the first which he had ventured to call together; and an act was passed declaring him undoubted king of the realm, and settling it upon his son Edward, prince of Wales. The marriage of Edward IV. with Elizabeth Woodville was declared null, and his son pronounced a bastard: then followed a severe bill of attainder, in which several noblemen, bishops, knights, and gentlemen, were deprived of their estates, honours, and rights.

But notwithstanding all the measures of severity adopted by Richard, he was seriously alarmed at the projected marriage between Henry of Richmond and the eldest

daughter of the late king. To defeat this project, therefore, now became the chief policy of the king. The princess was induced to quit her sanctuary and come under the protection of Richard, who probably had destined her for his son; but the death of that prince forced him to alter his plans, and secure her for himself. Lady Anne Neville, Richard's queen, was in infirm health, and this induced him secretly to make an offer of his hand to the young princess, which she agreed to accept. During the illness of Anne, Elizabeth discovered, it is said, an unnatural degree of impatience, and hinted her surprise at its duration; a most suspicious circumstance. Her apprehensions, however, were soon allayed. In less than a month the queen died; but her hopes of sharing the throne with Richard were not realized. The match was so very unpopular that the royal wooer was dissuaded from his purpose, and his attention was soon directed to another quarter.

The crimes of Richard had alienated the greater portion of the York party from his interests; and a union between Elizabeth and Henry, for the purpose of reconciling conflicting factions, became a topic of serious consideration. The latter prince again conceived the hopes of seizing the crown by another invasion of England; and having collected an army of three thousand men, he set sail from Harfleur early in August 1485, and landed at Milford Haven on the 6th of that month. Richard affected to hear the intelligence with joy; and displaying the vigilance and activity of his brother Edward, he marched from London on the 16th. His competitor had directed his march through the northern districts of Wales, a tract of country in the interest of the Stanleys. Both armies met at Bosworth in Leicestershire, on the 22d of August 1485, where a battle was fought, memorable for having restored tranquillity to the kingdom, which had so long been the theatre of sanguinary civil wars.

The army of Richmond amounted to about six thousand men, that of the king to nearly twice the number, and both prepared for the contest, equally confident of victory. For, notwithstanding the inferiority of Richmond's troops, he was secretly encouraged by the promises of Lord Stanley, who was hastening, with seven thousand men under his command, apparently to join the royalists, but really with the intention of siding with Henry. Stanley continued his march slowly; and on the morning of the battle he took up a neutral station on the wing of either host. The king entrusted his vanguard to the Duke of Norfolk, whilst that of Henry was assigned to the Earl of Oxford; and the two competitors for the crown placed themselves at the head of the main bodies of their respective armies. Richard, taking advantage of a marsh which covered his right flank, ordered a shower of arrows to be discharged into the adverse ranks, which for a moment threw them into confusion. He sent orders to Stanley to join him immediately; but the refusal of that nobleman to comply with his request shook his confidence and also that of his army, which now began to waver. To complete his dismay, he saw Stanley join the ranks of Henry, a circumstance which determined the fortune of the day. But, in order to retrieve it, Richard made a vigorous effort worthy of a better cause. Chancing to observe Henry in the midst of the conflict, he made a dash at him, determined to cut him down or perish in the attempt. He slew with his own hand Sir William Brandon, the bearer of the hostile standard, unhorsed Sir John Cheney, and was within a blow of his rival, when he was overpowered by numbers, struck to the ground, and immediately slain. After his fall resistance was hopeless, and his army broke up and dispersed. The crown which he wore on that day was taken up by Lord Stanley and placed on Henry's head, who was instantly greeted with shouts of "Long live King Henry." Of Richard's army a considerable number were killed in the battle and pursuit, and amongst these were the Duke of Norfolk, and Lords Ferrers, Radcliff, and Brackenbury. The victors lost but few, and none of any note except their standard-bearer. To enhance their triumph, Lord Strange, the son of Stanley, whom Richard had ordered for execution before or during the conflict, escaped in the confusion and rejoined his father. The body of the tyrant was thrown carelessly across a horse and conducted to Leicester, where it was interred with small ceremony.

Of Richard's character little remains to be said. The crimes of which he was undoubtedly guilty almost remove him from the ranks of mankind, and class him with the most ferocious animals. The arguments which have been brought forward in modern times to prove his innocence are inconclusive, and scarcely to be named, when confronted with the mass of evidence which may be arrayed against him. His fall excited no regret, except amongst a few of his partizans, the slaves of his despotic will. How could it? The death of his unoffending nephews must have still been fresh in the memory of his subjects.

The quarrel between the houses of York and Lancaster was now brought to a conclusion. In order to secure the blessings of peace and an undisputed succession, it was necessary for Henry at once to espouse Elizabeth, and, by so doing, to blend the white and the red roses together. There is no concealing the fact that his title to the crown was of a very ambiguous description. It rested on three grounds, first, his marriage with Elizabeth; secondly, his descent from the house of Lancaster; and thirdly, the right of conquest. According to the sagacious Bacon, "he rested on the title of Lancaster in the main, using the marriage and the victory as supporters." But this main support was not a valid one; for even allowing his descent from John of Gaunt to have been legitimate, he was not the nearest descendant of that prince's children. There were several who had claims superior to his; but the individual whom Henry looked upon with peculiar jealousy was Edward Plantagenet, son of the late Duke of Clarence. After the death of this prince's father, Richard sent for him to court, and created him Earl of Warwick, the title borne by his grandfather; but fearing that he might afterwards become a dangerous competitor, Richard had him conveyed to a distant fortress; and one of the first acts of Henry was to change his place of confinement, and put him in the Tower, as a prison of greater security. Elizabeth, who had been his fellow-captive, was ordered to be conducted to the house of her mother in London, whilst Henry himself leisurely followed her to the capital. He was received there with every demonstration of joy, and greeted by the inhabitants as the deliverer of his country. His coronation was delayed for a time, by the breaking out of a dreadful disease, called from its predominant symptom the sweating sickness. But at the end of a month its virulence began to abate, and Henry was crowned on the 30th of October 1485. To heighten the splendour of the ceremony, he bestowed the rank of knights-banneret on twelve persons, and conferred peerages on three. Jasper earl of Pembroke, his uncle, he created Duke of Bedford; Thomas, Lord Stanley, his father-in-law, Earl of Derby; and Edward Courtenay, Earl of Devonshire. At the coronation likewise appeared a new institution, which the king had established for personal security as well as pomp; a band of fifty archers, who were denominated yeomen of the guard. But lest the people should take umbrage at this step, as if it implied a diffidence in their loyalty, he declared the institution to be perpetual. The ceremony of the

coronation was performed by Cardinal Bourchier, archbishop of Canterbury. On the 18th of January 1486, Henry was united to the Princess Elizabeth; and his marriage was celebrated at London with even a greater appearance of joy than either his first entry or his coronation.

The reign of Henry VII. was for several years disturbed by plots and insurrections. The people, by a long course of civil war, had become so turbulent and factious, that no governor could rule, nor was any king likely to please them. The violent animosity expressed by this monarch, however, against the house of York, may justly be considered as one of the causes of the extreme proneness to rebellion which was manifested amongst his subjects. Instead of endeavouring to conciliate the affection of the opposite party, he invariably strove to quell them by force and violence. For this purpose, soon after his accession he took a journey to the north of England, where the Yorkists were very numerous, trusting that his presence might overawe them. On his way thither he received intelligence of an insurrection against him, headed by Viscount Lovel, with Sir Henry Stafford and his brother Thomas. The two latter had raised an army, and were marching to besiege the city of Worcester; whilst Lovel was hastening to their assistance with a body of several thousand men. But they were induced to disperse by the offer of a general pardon. Lovel withdrew from his troops, who immediately gave in their submission to the king. The Staffords took refuge in the church of Colnham, near Abingdon; but they were dragged from this sanctuary, as it was found not to possess the privilege of sheltering rebels. The elder brother was executed at Tyburn, but the younger one received a pardon.

Henry returned from his northern tour, and soon afterwards his queen presented him with a son, whom he named Arthur, in honour of the supposed progenitor of the house of Tudor, the renowned King Arthur; but Henry was not permitted to enjoy undisturbed security. He never was at any time popular except amongst his own party; and in the northern counties, particularly, the late King Richard was remembered and spoken of with regret. Henry was hated for his success, and even charged with having put to death the young Earl of Warwick, whom he had imprisoned, as has already been mentioned. It was necessary for the king to exercise extreme caution, on account of the dangers which surrounded him; and hence he is described as having been mysterious and impenetrable. Sir Thomas More remarks that one thing was frequently pretended whilst another was meant; and Bacon says that the king had a fashion rather to create doubts than assurance. The birth of his son seems to have roused his enemies to make some exertions against him; and being destitute of any chief of sufficient ability round whom insurgents might rally with any hope of success, they were urged to make one of the most extraordinary attempts recorded in history. One Richard Simons, a subtle priest of Oxford, took under his charge Lambert Symnel, the son of a tradesman belonging to the same town. The boy was about eleven years of age, comely, and not without dignity and grace in his person. With this individual, who was well tutored to perform the extraordinary part which was to be assigned him, the churchman landed in Ireland, and presented him to the lord-deputy of the county as Edward Plantagenet, earl of Warwick, who had made his escape from the Tower. It seems to have been at first the design of the fabricators of this singular deception to have presented him to the public as the younger of the princes who had been put to death by Richard in the Tower. In order to further this scheme, a report was circulated that one of these princes had made his escape from his assassins. Why this plan should have been changed, and the youthful impostor seduced to personate an individual still living, it is difficult to conjecture; but such is the fact. The Earl of Kildare, to whom he was presented in Ireland, swallowed the bait, and allowed the claims of Symnel without discussion. This nobleman was a zealous adherent of the house of York; and the little colony called the English Pale, long ruled by that party, retained all its ancient attachments. A belief in the identity of Symnel with the Earl of Warwick became universal, both amongst the nobility and the people. He was lodged in the castle of Dublin; the inhabitants universally took an oath of allegiance to him, as the true descendant of the Plantagenets; he was crowned with a diadem taken from the statue of the blessed virgin, and proclaimed king by the title of Edward VI.

Such an unexpected event so alarmed Henry that he would have gone over to Ireland in person to quell the rebellion, had he not dreaded the machinations of the queen dowager in his absence. To prevent any thing of this kind from occurring, it was resolved to confine her for life in a monastery, under pretence, however, that it was done on account of her having formerly delivered up the princess her daughter to King Richard. The royal dame murmured at the severity of her sentence; but the king persisted in his resolution, and she remained in confinement till her death, which did not take place till some years afterwards.

The next measure was to exhibit the person of Warwick to the people. That prince was accordingly taken from the Tower, and conducted through the principal streets of London; after which the procession moved to St Paul's, where great numbers were assembled to see him. Still, however, the fictitious Warwick prospered in Ireland, and being furnished by the Duchess of Burgundy with a body of two thousand veteran Germans, under the command of Martin Swart, a brave and experienced officer, the invasion of England was determined upon. He landed in Lancashire, whence he marched towards York, expecting that the country people would rally round his standard during his march. But in this he was disappointed; the people were unwilling to join a body of foreigners, and were besides kept in awe by the reputation of Henry. Lord Lincoln, therefore, who commanded the rebel army, determined to bring the matter to a speedy issue. Accordingly he met the royalists at Stoke, in the county of Nottingham, and an obstinate engagement took place, which terminated in Henry obtaining a complete victory. Lord Lincoln, with four thousand soldiers, perished in the action; and Symnel with his tutor Simons were taken prisoners. Simons being a priest, could not be tried by the civil power, and was only committed to close confinement. Symnel was pardoned, and made a scullion in the king's kitchen, whence he was afterwards advanced to the rank of falconer, in which capacity he died. Thus ended this most absurdly planned and injudiciously executed revolt; but it was not destitute of good results. It taught the king that the house of York was not to be trampled upon with impunity; for to such an extent had his antipathy to the branches of that family and its adherents been carried, that it was said his own queen was not exempt from the common odium which was thrown upon them. It was asked by the people, why was she, the rightful heir to the throne, not crowned, and invested with the usual insignia of royalty? Henry silenced these rumours by ordering her coronation; and from that period she shared with him the usual honours of royalty.

Having thus to a great extent established his authority at home, he thought of diverting the minds of his subjects from domestic insurrection to foreign enterprise. He

History. 1487. does not appear, however, to have had any intention of prosecuting a serious war in a distant country, but he used the pretext as a means of aggrandising himself. A parliament was summoned, which granted the king a considerable sum for prosecuting the war in Bretagne, the only great fief of the French crown which still retained its own prince and its ancient constitution; by force, by policy, or by good fortune, the French monarchs had obtained possession of all the others. But of the supply granted by parliament, only a small part could be raised. The northern counties not only refused payment of their proportion, but rose in revolt, and murdered the Earl of Northumberland, the king's lieutenant. The insurrection, however, was quickly suppressed by the Earl of Surrey. John a Chambre, one of the ringleaders, suffered at York; and Sir John Egremont, the other, escaped to the Duchess of Burgundy, where he had leisure to hatch new schemes of rebellion. The money which Henry by this means obtained, and also in consequence of another grant from parliament, was quietly deposited in his coffers. For although he collected a considerable army, with which he proceeded to Calais, the king had other objects than victory and conquest in view. Some months previously to his landing on the Continent, he had commissioned the governor of Calais to negotiate a peace and alliance with Charles of France, which was formally concluded. To the French monarch the possession of Bretagne was an important object; and Henry, naturally avaricious, agreed to accept about L.200,000 as a reimbursement for the expenses of the expedition. It was also stipulated that the king of France should pay to him and his heirs an annual pension of 25,000 crowns.

But Henry's hopes of a tranquil possession of the crown of England were doomed to perpetual disappointment. His reign was now to be disturbed by one of the most mysterious personages to be met with in English history. About the time when war was declared against France, a pretender to the regal dignity appeared in Ireland, which seems to have been the natural soil for these spurious shoots of royalty. This impostor passed under the name of Perkin Warbeck, but asserted himself to be Richard duke of York, the second son of Edward IV. who, it was alleged, had escaped from the Tower when his brother was murdered. Previously to his appearance in Ireland, he had been heard of at the court of Margaret, his supposed aunt, who interested herself to the utmost in his favour, and fondly styled him the White Rose of England. But he was compelled to quit Burgundy; for Henry had dispatched some ambassadors to the sovereign of that country, with secret instructions to demand either the person of the impostor, or his expulsion from the territories of the duke. Warbeck was received with open arms in Ireland, for the Irish were fanatically attached to the house of York. Several noblemen who had credulously believed in the fraud of Symnel, from which they had just escaped, gave countenance to his pretensions. A deputation was sent to Flanders to ascertain his history; but they had been corrupted by Henry before their landing in Burgundy, and they returned fraught with charges of treason against the disaffected nobility. Some of the most eminent malcontent Yorkists were put to death, and amongst the rest Sir William Stanley, lord-chamberlain, to whom the king had owed his life on Bosworth field. His fate was most mysterious, and the conduct of Henry upon this occasion is open to the most odious suspicions. Sir Robert Clifford, the individual whose information led to these executions, was a confidential Yorkist; and his behaviour towards his own party, so different from what might have been expected, tended to dissolve the ties which subsisted between it and the malcontent exiles.

Three years had now elapsed since the pretender had set forth his claim, and during that period he had never attempted to establish it by legal proof. He began to feel that he stood upon delicate ground, and resolved at once to enforce his pretended right by an appeal to the sword. With a small force collected in Flanders (for he had been for some time absent from Ireland) he made a descent in the neighbourhood of Deal; but the adventurers were attacked by the inhabitants, and all of them driven back to their vessels, or taken prisoners. Warbeck himself made his escape, and returned in despair to Flanders. From this country he was ejected at the instigation of Henry; and after vainly attempting to gain a footing in Ireland, he set sail for Scotland, where he was well received by the young king, who professed a conviction in the justice of his title. King James conferred upon him the hand of Lady Catherine Gordon, a near kinswoman of his own. The adventurer's fortunes being thus suddenly elevated, he, along with the king of Scotland, advanced into England; but not a native sword was unsheathed in favour of the White Rose. The enthusiasm which had been excited amongst the Scots by his first appearance in their country had begun to decline, and during a long truce, which served all the purposes of a treaty of peace between James and Henry, it was agreed to by the former that he should induce Warbeck to quit Scotland. The adventurer, with a few adherents, accordingly departed, and, after touching once more at Cork, and in vain soliciting the aid of Earl Desmond, steered for Cornwall, where he landed on the 7th of September 1497.

History. 1501.

His arrival in this part of the country was a politic step, for an attempt to raise a tax there some time before gave rise to an insurrection, which, although quelled, left behind heartburnings and discontent. A considerable body of Cornish men joined his standard, and before he reached Exeter his army amounted to six thousand men. But the king arrived, and preparations were made for a battle; the heart of the pretender, however, failed him at the sight of the royal standard, and instead of risking an engagement for the crown, he withdrew during the night, and entered his name in the sanctuary of Beaulieu in Hampshire. His followers laid down their arms to the king, and his wife also submitted to his authority, and was placed near the person of the queen. From his sanctuary the fugitive was removed by the king to London, where he was ordered to keep within the precincts of the palace. He contrived, however, to make his escape, but, despairing of getting out of the country, surrendered himself to the prior of the monastery of Shene. The monk contrived to prevail with the king to spare his life; but he was condemned to stand in the stocks and make a public confession of his imposture, after which he was committed to the Tower. In this fortress he met with a singular companion, the real Earl of Warwick, who had now been a prisoner for the period of fourteen years. His life had thus been passed in cheerless captivity, for no other offence than that of being the sole survivor of the male descendants of Edward III. The two contrived a means of escape, but they were discovered. Warbeck was executed at Tyburn; and the son of Clarence having been arraigned for high treason, was condemned to death and beheaded on the 28th of November 1499. This deed was worthy of Richard III. It was a cool-blooded murder, aggravated by circumstances; for the harmless and joyless victim was, from his long confinement, reduced to a state of idiocy. The human soul shudders to think of such atrocities, perpetrated in defiance alike of justice and humanity. From the guilt of shedding innocent blood it is impossible to purify the name of Henry VII.

In 1501, the king's eldest son Arthur was married to

History. 1501.

the Infanta Catherine of Spain; but he survived the marriage only a few months, having died on the 2d of April following. It was agreed upon a short while afterwards, by the parents of the parties, that the widow of the late prince should be espoused by Henry's next son, now Prince of Wales, and afterwards Henry VIII. The union was sanctioned by the pope, who granted a bull, dispensing with any impediment which their affinity might otherwise cause. The eldest daughter of King Henry was conferred upon James IV. of Scotland; an important union, as from this stock sprung all the sovereigns who have since reigned in Great Britain. King Henry, in his own time, was called the Solomon of England; and, without allowing him to possess undisputed claims to so high-sounding a title, the saying recorded of him regarding the Scottish marriage displays no common foresight and sagacity. When some of his counsellors objected to it, on the ground that the kingdom might thereby fall to the king of Scotland, he answered, " Scotland would then become an accession to England, not England to Scotland; the greater would draw the less; it is a safer union for England than one with France."[1]

In the latter part of this king's reign, his economy, which had always been very exact, degenerated into avarice, and his oppressions at last became severe. In Empson and Dudley he possessed two ministers, who did all that inventive minds could suggest, and hearts of stone perform, to gratify a rapacity, which fed with equal appetite on friend and foe. We are informed by one of the wisest of historians and of men, that these individuals had no reputation, otherwise than by servilely following his bent, and that they " shaped his way to those extremities for which himself was touched with remorse at his death."[2] The hoard which the king had amassed by their unjust extortions, and which was mostly kept in " secret places at Richmond," is said to have amounted to nearly L.16,000,000 of our present money. This amount of specie is so enormous as to warrant a conviction that it has been greatly exaggerated. It may be doubted whether the whole circulating medium of the country at that period amounted to the sum which the avaricious monarch is said to have accumulated.

Henry, who had enjoyed an uncommon share of health during his life, was at fifty-two years of age attacked by severe indisposition. He died on the 21st of April 1509, in the twenty-fourth year of his reign, which, although perpetually disturbed by domestic insurrections, was upon the whole prosperous. He was interred in the chapel at Westminster, which still bears his name; one of the noblest trophies of architectural genius produced in any age, and which confers peculiar distinction upon that in which it was erected. There are many acts of Henry's administration, and some of these have already been particularised, which cannot be related but to his discredit. He was mean, sordid, and unamiable in his nature. No tenderness softened his rigid nature, if we except that which he evinced towards his mother; a virtue, however, too common to be praised even in a king. We see no qualities about the man which inspires us with regard for him; but there are many virtues to admire in the ruler. He favoured every national improvement; and, though penurious to excess in ordinary or essentially private matters, he was munificent in public works. He greatly improved the laws of the realm. With respect to these, Lord Bacon remarks, with his usual clearness and sagacity, " his laws are deep, not vulgar; not made upon the spur of a particular occasion, for the present, but acts of prudence for the future, to make the estate of his people still more happy, after the manner of the legislators in ancient and heroical times." He manifested great regard for trade, as is evinced by his excellent laws for promoting it, and by the extended commercial intercourse of the country. He accepted the offer of Columbus to make that most memorable of voyages, in which he lifted the veil that covered a grand division of the globe, and would have patronized it if he had not been forestalled by Isabella. He gave his sanction to Cabot's celebrated voyage (see CABOT), and fitted out a ship to join the expedition. In fine, the country improved under his government, and became steadily attached to his family

History. 1512

Henry VIII. son of the preceding monarch, ascended the throne on the 22d of April 1509, being then in the eighteenth year of his age. He assumed the reins of government under most auspicious circumstances. His title was undisputed; his treasury was well stocked; commerce was in a flourishing condition; and the kingdom, which now may be supposed to have looked to the youthful monarch with hope and indulgence, was at peace with every foreign power, and quiet in itself. He was prepossessing in person, accomplished in mind, and adroit in every martial and fashionable exercise. But these advantages belonged to an individual whose heart was usurped by debasing passions, and whose mind was cast in the true mould of despotism.

On the 6th of June 1509, Henry and Catherine were finally united in wedlock, and on the 24th of the same month they were crowned with great splendour. One of Henry's first acts was to bring Empson and Dudley, the obnoxious ministers of his father, to trial. As a capital accusation could not be brought against them for merely executing the will of the late king, it was found necessary to indite them for a conspiracy to seize upon London with an armed force during the last illness of Henry. Of this charge, absurd and incredible as it appears to be, these individuals were convicted; and though it seems probable that the king would have been satisfied with imprisonment for life, yet so clamorous were the people for the blood of the culprits, that he was compelled to sign a warrant for their execution, which took place on Tower Hill.

In 1511, Henry entered into a league with Pope Julius II., Ferdinand king of Spain, and other continental powers, against Louis XII. of France. In this alliance the king of England was not a deeply interested individual; but his vanity was flattered with the idea of receiving the title of Most Christian Majesty, which was promised to him by the pope. The object which the confederates had in view was to wrest from Louis some valuable provinces which he had obtained in Italy; and although Henry had no hope of sharing the spoil with them in this quarter, yet the occupation of the French monarch in schemes of aggrandisement beyond the Alps afforded an opportunity to the English of invading France, and reviving the old chimera of conquering that country. The point, whether England should aim at continental dominions, was debated in parliament; and the arguments against it greatly preponderated. But the vanity of Henry was too much flattered to relinquish the scheme. He sent an ambassador to demand of Louis the ancient patrimony of the English crown in France, and this being refused, war was denounced. Parliament granted a supply, and an army was equipped and sent into Spain. But this expedition was attended with no success, and the troops, dispirited and mutinous, returned to England towards the close of 1512. On the north-western frontier of France, however, the arms of Henry were triumphant, and also in Scotland,

[1] Bacon, iii. 409.

[2] Ibid. iii. 379.

History. 1513. which had been tempted by French councils to invade England. James IV. with a considerable army under his command, was met by the Earl of Surrey at Flodden, where a bloody battle was fought, in which the Scots were totally routed, and their king, with the greater portion of his nobility, perished. (See SCOTLAND.) Henry received the news of this victory at Tournay, which he had invested, after having demolished Terouanne. The latter city opened its gates to him in eight days; but all parties being now disposed for peace, a general treaty was concluded in August 1514.

With regard to the administration of government in England, when Henry mounted the throne, the leading ministers in the cabinet were, Howard, earl of Surrey, lord treasurer; and Fox, bishop of Winchester, lord privy seal. Amongst the inferior dependents of the court there now appeared an individual, whose ambition and talent enabled him speedily to supplant every competitor. This was Thomas, afterwards Cardinal Wolsey, who, although only the son of a burgess of Ipswich, gradually raised himself to the first offices of state. (See WOLSEY.) His preferment had been rapid beyond all precedent, and this was not likely to be forgiven by an envious world. From the year 1513 to 1515, he had passed through the various gradations, from being bishop of Tournay, to the honours of the cardinalate, and he succeeded Archbishop Worham in the office of chancellor. With respect to the manner in which he executed his duty as a high public functionary, Sir James Mackintosh remarks, that "his administration of justice as chancellor has been celebrated by those who forget how simple the functions of that office then were; and his rigid enforcement of criminal justice appears only to have been a part of that harsh but perhaps needful process by which the Tudor princes rather extirpated than punished criminals, in order to reclaim the people from the long license of civil wars. As he was chiefly occupied in enriching and aggrandizing himself, or in displaying his power and wealth, objects which are to be promoted either by foreign connections, or by favour at court, it is impossible to determine what share of the merit or demerit of internal legislation ought to be allotted to him. His part in the death of the Duke of Buckingham was his most conspicuous crime; yet, after all, it is probable that he was no worse than his contemporary statesmen. The circumstance most favourable to him is the attachment of dependents."[1]

On the death of Maximilian, which happened towards the end of the year 1519, Henry, along with the kings of France and Spain, became a candidate for the imperial throne. The Spanish monarch was the successful competitor, and, to soothe the wounded pride of Henry, he paid him a visit of ceremony at Dover. His principal design in this was to persuade Henry to abandon a projected meeting which was to take place between him and the king of France, the wily emperor dreading that such an interview might be fraught with danger to himself. He was unsuccessful, however, and the two monarchs met between Ardres and Guines in 1520. The place where this meeting was held has been long celebrated under the name of the Field of the Cloth of Gold. The pomp and parade, the tournaments and other sports of the age, exhibited upon the occasion, were on the grandest scale, and peculiarly calculated to delight the young king of England, a creature of impulse, and one who sacrificed policy to temper, and interest to passion. It was thus that the continental monarchs flattered his foibles, and ingratiated themselves into his favour.

About the same time a crime was perpetrated, in the guilt of which both Henry and his minister Wolsey have been implicated; we mean the execution of Edward Stafford, duke of Buckingham. This nobleman was descended from the youngest son of Edward III.; and the principal accusation brought against him was, that he had tampered with a priest who laid claim to the gift of prophecy, and who had foretold that he would yet ascend the throne in virtue of his descent. Several other charges equally absurd, and not amounting to an overt act of high treason, were brought against him; he was tried by a jury of peers, condemned to death, and beheaded on the 17th of May 1521. Upon this occasion the populace vented their indignation against Wolsey, whose subtle policy had brought the sufferer to the scaffold, by loud cries of "the butcher's son." History. 1527.

Wolsey, however, continued to rule with unabated sway from 1521 till 1527. This period is not distinguished by any events of importance, if we except the opposition which the House of Commons offered to the minister in his attempts to raise supplies. That body obstinately disputed these grants, and attempts were made to raise money by the expedients of forced loans and pretended benevolences, which the legislature had already condemned. But these attempts produced a small supply and a great deal of discontent. Wolsey, notwithstanding his unwearied exertions in behalf of his master, never felt himself perfectly secure in his elevated situation. The capricious and tyrannical temper of Henry forbade his ministers to be at ease in any place of trust near his person. The fall of Wolsey seems always to have appeared to himself as an event of very likely occurrence, and these gloomy forebodings were at last realized. The cause of the rupture between the king and him was the divorce of Queen Catherine, which the former had begun to project. But the fall of Wolsey was not the only event connected with Henry's divorce; it ultimately led to one of the most memorable transactions in the history of England, namely, the separation of that country from the communion of the church of Rome.

The doctrines of the reformation, propagated by Luther in 1517, had gained considerable ground in England, and many professed a belief in them, notwithstanding the severe persecution which had been carried on against heretics during some of the preceding reigns. The papal authority, though still very great, had in the space of ten years declined considerably; but a detail of the circumstances connected with this subject is not required in this place. It may be noticed in general, that the reformation in England was facilitated by the undeniable corruption of the clergy, and the experience which many individuals had of, and the partiality which they entertained for, the doctrines of Wickliff. The seed sown by that divine had never been destroyed; and if it did not show itself above ground, it was extending itself underneath, perpetuating a sort of dormant existence, and ready to spring up on the first propitious occasion. Besides, the marriage of King Henry was looked upon by many as in itself illegal, and only sanctified by a dispensation from the pope.

Whether Henry himself, during the early years of his reign, felt any scruples about the validity of his marriage, may reasonably be doubted; for no trace of any thing of the kind can be discovered in his public conduct till the year 1527. The queen was some years older than himself, and was now past the meridian of life. Her personal charms had decayed, and the heart of the royal sensualist could not be attracted by beauty that belonged purely

[1] *History of England*, vol. ii. p. 121.

History. 1527.

to the mind. She had born him several children, all of whom died in infancy except the Princess Mary, who survived both her parents, and afterwards ascended the throne. It is reported of the inconstant monarch, that he attributed the mortality in his family to the curse of heaven, which blighted his unnatural alliance with Catherine, his brother's widow. But there was another and more powerful circumstance which led him to contemplate a divorce from his queen; this was the love which he had contracted for Anne Boleyn. The charms of this lady had touched his fiery but not unsusceptible heart; and as his passion could not be gratified except by means of an alliance sanctioned by law, he set seriously to work for the purpose of removing the amiable partner of his throne and bed, and placing the youthful beauty in her stead. The secret intentions of the king having become to some extent public, he ventured to ask the opinions of the most eminent ecclesiastics upon the point. The dangers of a disputed succession, if the king should die without male issue, were brought forward as an urgent plea for taking the step which he had in view. He had also recourse to his theological lore, and certain religious scruples connected with his first marriage helped to give a colour of principle to his real desires, and at the same time to impart to them life and warmth. Some of the divines whose counsel was asked declared that no dispensation could authorize a marriage with the widow of a brother; which they proved from a passage in the Pentateuch. Others, who also founded their arguments upon a portion of Scripture, contended that the prohibition referred to by the opposite party was not universal, and might be dispensed with in the king's case, where the first marriage had been unproductive of issue. Cardinal Wolsey, who had a hazardous game to play, coincided with the former, and gave Henry hopes that his petition to the court of Rome would be successful. But Anne was not the individual whom the prelate had in his eye as a wife for the king. He was desirous of wedding his master to a French princess, and, we are informed, threw himself on his knees before Henry, and entreated him to desist from a project so unworthy of his birth as an alliance with the Boleyn family. But the pliant mind of the cardinal yielded to the impetuosity of his master and to the force of circumstances; and he found it necessary to atone for his indiscreet zeal by displaying redoubled activity to promote the marriage with the lady upon whom the king had fixed his affections. The illustrious Sir Thomas More declined to support the divorce, and Fisher bishop of Rochester acted with the same integrity.

A deputation was sent to Rome by Henry for the purpose of sounding Pope Clement upon the subject of the divorce. The pontiff was in a situation unfavourable to the success of the application; and although he was bound to the English monarch by the ties of gratitude, he declined giving an immediate assent to the proposition, but appointed two legates to hear and determine the validity of the first marriage of Henry. He also gave a solemn promise not to recall the commission, nor to do any act which should annul the judgment or prevent the progress of the trial. The pontiff was at this period engaged in a contest with the imperialists; but he at last concluded a treaty of alliance with the emperor, who appeared the only potentate capable of shielding him from his other enemies. The forensic disputes respecting the divorce still remained unsettled, and, from the date above mentioned, Clement took his final part against the degradation of the queen of England, who was an Austrian princess. But still, by ingenious delays and plausible formalities, he contrived to amuse Henry, whose power it was not his interest to treat with direct contempt. The patience of the English monarch, however, was now completely worn out by these fruitless attempts at negotiation, and he redoubled his entreaties to the pope to comply with his demands. Clement, in order to show a willingness to acquiesce in the wishes of Henry, sent over Cardinal Campeggio, who, either separately or in conjunction with Wolsey, was empowered to hear and determine the matrimonial suit. The legate at first attempted to dissuade Henry from pursuing the divorce; but being unsuccessful with the monarch, he next tried to persuade Catherine to embrace a religious life, in which he also failed. The popular feeling was against Henry, and he felt himself compelled to remove Anne Boleyn from court, where she had for some time resided. At a great council which he convoked, he declared that in prosecuting this matter he was solely actuated by a desire to know whether or not his only remaining child Mary was the rightful heir of the crown. On this occasion he made an appeal to the feelings and consciences of his hearers which affected them much; and the perplexities consequent upon the late proceedings afforded Campeggio an opportunity for putting off the decision of the question until he had obtained further instructions from Rome. Meanwhile Clement was seized with a dangerous illness, which retarded his answer, and is said to have revived in the ambitious mind of Wolsey a hope which he had before indulged in, of obtaining possession of the tiara. This occurred in the spring of 1529; and although the pope recovered from his sickness, his legate contrived from time to time to postpone the trial. On the 31st of May, however, the court of parliament met, and summoned the king and queen to meet on the 18th of June. The latter obeyed, but protested against the judges, and appealed to the pope. At the next session, on the refusal of the cardinals to admit the appeal, she rose, and in a calm and dignified manner threw herself at Henry's feet, imploring him in a truly eloquent address to desist from his intended purpose of repudiating her. It made a profound impression upon the audience, and even touched the cold heart of her husband. The legates carefully prolonged the trial until July, when a vacation from July to October took place, during which time all courts were bound to suspend their sittings; and, notwithstanding the importunities of the king, Campeggio contrived to get the suit removed to Rome. Agreeably to the instructions of Clement, Campeggio quitted England, and the pope summoned Henry to appear before him in forty days.

History. 1529.

In these transactions Wolsey took no inconsiderable share, and the compliant manner in which he gave his consent to the suggestions of Campeggio excited the suspicions of the king, that his minister was playing a double game with him. The symptoms of approaching disgrace now became too palpable to escape the notice of the cardinal; for all parties joined either openly or privately to destroy him who had so long enjoyed the favour of the king. It was a singular coincidence that the friends both of Queen Catherine and Anne Boleyn were employed as instruments of his overthrow. On the 9th of October 1529 a prosecution was commenced against him for procuring bulls from Rome without the king's license. On the 17th of the same month the great seal was taken from him and given to Sir Thomas More. On the 1st of December the lords presented an address to the king, in which were embodied various articles of accusation against the cardinal; and notwithstanding that the more serious parts of the charge were refuted by his servant Thomas Cromwell, the court at last pronounced him to be beyond the protection of the law, and "that his lands, goods, and chattels were forfeited, and that his person was at the mercy of the king." Wolsey had confessed his offence against the statute of *præmunire*, of which he was technically guilty,

History. 1529.

inasmuch as he had received the bulls without a formal license. It is scarcely necessary to observe that the sentence pronounced was most unjust; for the bulls had been obtained with the consent and for the service of his ungrateful master, under whose eye they had been executed for years without a word being uttered as to the manner in which they had been obtained. But nothing could now save the cardinal. He was at once hurled from his place of pride and power, and fell, with his vast possessions, a helpless victim, into the hands of the king. But it would appear that, from habit perhaps, Henry still cherished a feeling of partiality for his old favourite, and sent him from time to time tokens of his esteem and regard. In February 1530 Wolsey was actually pardoned, and restored to his see of Winchester, and to some other emoluments. Even the great diocese of York was shortly afterwards restored; but at the moment when he was making magnificent preparations for his installation on the archiepiscopal throne, he was arrested at Cawood on a charge of high treason. His health was infirm, and during his journey from York he was seized with a dysentery, which confined him for some time at the seat of Lord Shrewsbury. As soon as he was able he mounted his mule and resumed the journey. But his strength rapidly declined, and he was compelled to take refuge in the abbey of Leicester, where he expired on the 30th of November 1530, in the sixtieth year of his age.

After the death of Wolsey, the king, by the advice of his ministers, had the legality of his marriage debated in all the universities of Europe. (See the article CRANMER.) By dint of money he succeeded in obtaining their votes in his favour, but not without a stubborn opposition. Backed by these judgments, Henry appealed to the pope; but Clement remained inflexible, and the king prepared to resist the papacy, though not yet to separate himself entirely from the church of Rome. In 1532 Cranmer was elevated to the archbishopric of Canterbury; and early in the following year Henry privately married Anne, and thus himself determined the long debated topic. A few months afterwards he openly solemnized his marriage with Anne, who went in state with him as queen. On the 23d of May Cranmer pronounced, not a divorce, but a sentence that the king's marriage with Catherine had been and was a nullity, because it had been contracted and consummated against the divine law; and not long afterwards he confirmed the marriage of the king with the Lady Anne, whose coronation was performed in the most gorgeous manner on the first of June 1533. (See BOLEYN.) The unfortunate Catherine, perceiving all further opposition to be vain, retired to Ampthill, near Dunstable, where she remained for the rest of her days in privacy and peace.

The pope was no sooner informed of these proceedings, than he passed a sentence declaring Catherine to be the king's only lawful wife; requiring him to take her again, and denouncing censures against him in the event of refusal. Henry, on the other hand, knowing that his subjects were entirely at his command, resolved to separate altogether from the church of Rome. In the year 1534 he was declared head of the church by parliament; the authority of the pope was completely abolished in England; all tributes formerly payable to the holy see were declared illegal; and the king was intrusted with the collation to all ecclesiastical benefices. The nation readily entered into the king's measures, and took an oath called the *oath of supremacy;* all the authority which the popes had maintained over England for ages was overthrown at a blow; and none seemed to repine at the change except those who, from their dependence upon Rome, were immediately interested.

History. 1535.

But though the king thus separated from the church of Rome, he by no means adhered to the doctrines of Luther which had been lately promulgated. He had himself written a book against this celebrated reformer, which the pope pretended greatly to admire, and honoured King Henry, on this account, with the title of Defender of the Faith. This character he seemed to be determined to maintain, and therefore persecuted the reformers most violently. Many were burnt for denying the Catholic doctrines, and some also were executed for maintaining the supremacy of the pope. The courtiers knew not which side to take, both the new and old religions being equally persecuted; and as both parties equally courted the favour of the king, he was by that means enabled to assume an absolute authority over the nation.

The established clergy co-operated actively in the revolution which was in progress. Six bishops sanctioned by their vote every blow which was struck at the power of Rome; and fourteen abbots were usually present when the number of temporal peers who attended were somewhat more than forty. "They did not shrink," says Sir James Mackintosh, "from the deposition of Catherine, by reducing her title to that of Princess Dowager of Wales. By ratifying the marriage of Anne Boleyn they adopted those parts of the king's conduct which most disgusted the people. The bill for subjecting the clergy to the king, as their sole head, was so favourably treated as in one day to be read three times and passed: no division appears to have taken place on these measures."[1]

The attention of the king was now turned to Elizabeth Boston, a nun in the priory of St Sepulchre at Canterbury, who believed herself endowed with the power of working miracles, and foretelling future events. Several clergymen and other gentlemen of Kent believed in her mission; and some individuals of the highest order, both of intellect and piety, gave credit to her pretensions. She was subject to convulsions; and in the trances into which she frequently fell, visions of a marvellous nature were vouchsafed to her, which turned of course upon the extraordinary events taking place around her. She was tried and executed for high treason, and her abettors were arraigned on the same charge. Fisher, bishop of Rochester, was attainted by the act against this modern Pythia; but by a separate statute he was afterwards attainted of misprision of treason, for not having taken the oath to the succession. He was eminent for his learning and virtue, and probably his life would have been saved had not the pope sent him a cardinal's hat while in prison, which roused the jealousy of Henry. The remorseless tyrant ordered him to be executed, at the same time remarking, with his usual heartlessness, that the pope might send him a hat, but that Fisher should have no head to wear it. Another deed of blood was perpetrated a short time afterwards, which alone is calculated to consign the name of Henry VIII. to the execration of all future times. Sir Thomas More, the first Englishman of his day, one who had exalted the nation in the eyes of Europe, and whose fame was universal, was tried and executed for misprision of treason, in not taking the oath to maintain the succession. The legal pretext, if there was any, for the accusation, was grounded on the obnoxious clause of a recent act, which made it treason "to do any thing by writing or act which was to the slander, disturbance, or prejudice of the marriage with the Lady Anne, or to the disherison or disturbance of the king's heirs by her." Both More and

[1] *History of England*, vol. ii. p. 175.

History. 1535

Fisher had abstained from either affirming or denying, first, that Henry's marriage with Catherine was invalid; secondly, that his marriage with Anne was valid; and, thirdly, they refused to disclaim all foreign authority in the kingdom. spiritual authority included. After his condemnation Sir Thomas avowed that he had studied the question for seven years, and could not escape from the conclusion that the king's marriage with Catherine was valid. For this scrupulous conscientiousness he expired upon the scaffold on the 7th of July 1535.

This wanton shedding of righteous blood excited the utmost indignation in foreign countries, particularly in Italy. Here Giovio, an historian, compared the tyranny of Henry to that almost preternatural wickedness which the Grecian legends had embodied under the appellation of Phalaris. Other individuals lashed the tyranny of the English monarch with the utmost rigour, and lamented, in strains of affecting eloquence, the fate of More, whom they designated the martyr of unshaken probity. Amongst the most eminent of these writers was Cardinal Pole, an Englishman, allied to the royal family.

Catherine, the former consort of Henry, expired at Kimbolton in the beginning of January 1536, having died as she had lived, mild, forgiving, and resigned. On her deathbed she wrote a most affectionate letter to her husband, whose iron nerves were touched by the perusal of it. His less prudent queen had the levity to express her satisfaction at the event. But if she expected that it would in any way be conducive to her further happiness, and a more devoted attachment on the part of her husband, she was most miserably disappointed. She soon after gave birth to a still-born child, and her brutal lord is said to have reproached her upon the occasion for the loss of his boy. His desire for male issue, and his repeated disappointments, seem to have at last weaned the affections of the fickle monarch from the idol whom he had worshipped with so much devotedness and ardour. A new passion had kindled in his breast, the object of which was Jane Seymour, a young lady of the queen's bed-chamber, which office Anne herself had held in that of Catherine. The circumstances connected with the queen's arrest may be briefly stated. On May-day 1536 a tilting match was held at Greenwich, in which her brother was the chief challenger, and Norris, groom of the stole, the opposing defendant. The queen having dropped her handkerchief, had it gallantly handed up to her by Norris, who was supposed to be her lover. The jealousy of the king burst out; he left the joust precipitately; and ere night his queen had passed through an examination, and was committed a prisoner. Such was the trifle "light as air," which to the jealous mind of Henry seemed a "confirmation strong as proofs of holy writ." By the researches of Mr Turner it has been discovered, that some days before the tournament certain individuals were appointed to inquire into the alleged misdeeds of Anne. The commission put their authority into execution upon the 10th of May, when a grand jury of Westminster was assembled. The charge against her was adultery, and its consequence in such a case, treason. Whether innocent or not, the unhappy Anne was deserted in her utmost need, and had not a friend to counsel her in this alarming emergency. On the day after the queen was committed to the Tower, Cranmer had written to the king imploring the king's mercy towards her, "his life so late, and sole delight;" but in vain. The archbishop had been forbidden to approach the court until desired by the king. The subsequent proceedings were as rapid as they were terrible. On the 12th of May, Norris, Weston, Brereton, and Smeaton, were tried in Westminster Hall for the crime of high treason. Smeaton pleaded guilty to the charge; the others resisted, but were convicted. Three days afterwards the House of Lords assembled for the trial of the queen. She was without counsel, and attended only by her ladies. Anne defended herself with modesty and firmness, but, upon evidence of which no traces now remain, she was condemned to suffer death. On hearing the sentence of her judges, she raised up her hands and exclaimed, "O Father and Creator! O thou who art the way, the truth, and the life! thou knowest that I have not deserved this death." It is difficult to reconcile such an ejaculation with a consciousness of guilt. She afterwards turned to her judges, and made a serious protestation of her innocence. On the 17th of May the other individuals who had been convicted were carried forth to execution. Smeaton, who had confessed to the guilt, probably from an erroneous impression that he would by this means save his life, was the last to suffer. Anne's brother Rochford was also tried and condemned on the same day with herself, and was executed with the others. The curtain dropped upon this horrible tragedy with the death of the queen, who was beheaded on the day after her supposed accomplices had suffered. For further particulars respecting this unhappy personage, see BOLEYN.

History. 1536.

That Henry sacrificed his queen in a fit of vindictive resentment against her, who, he too rashly believed, had dishonoured him, is all that can be urged in his favour That he really believed her guilty, must also in common fairness be allowed. To think otherwise would be to attaint his name with one of the most horrid enormities that ever disgraced the annals of crime. It seems very improbable that the violent attachment which he had all along entertained for her should have cooled so suddenly, and been supplanted by such deadly hate, without supposing that some levities in the conduct of Queen Anne had fired his jealous soul, and roused him to demand her blood as an expiation for the guilt imputed to her. But he was not content with taking away her life under the charge of adultery and incest; he deprived her of the name and the right of wife and queen, and bastardized the daughter which she had born him, even when he acknowledged that daughter to be his own. His contempt for her memory was displayed in a manner which could be believed of few other individuals. He dressed himself in white on the day of her execution, and actually married Jane Seymour next morning.

In bringing this tale of blood to a termination, we have unavoidably outrun several important events. When the news of Sir Thomas More's execution reached the court of Rome, a bull was prepared against Henry. In this extraordinary instrument were embodied all the offences of the English monarch against the papal see, and he was allowed ninety days, and his fautors and abettors sixty, to repent, and to appear at Rome either in person or by attorney. In case of default, he was to be excommunicated, and deprived of his crown; his children by Anne were to be rendered incapable of inheriting for several generations; his subjects were to be absolved from their allegiance to him; and all treaties and alliances between him and other powers were to be null and void. This thunderbolt, however, though forged for the purpose of punishing the king's apostacy, it was resolved should be suppressed for a time, and lodged in the papal armoury until a more favourable opportunity should occur for launching it at the royal culprit.[1] The election of Henry as supreme

[1] Thus far historians are perfectly agreed with regard to this bull. It is also certain, that in 1538 the suspension of the bull was revoked, and its publication ordered by the pope. But whether or not this really took place is a matter of doubt Dr Lingard ob-

History. 1536.

head of the church we have already noticed, and also some of the events which followed his assumption of that presumptuous title. Henry, however, at first assumed it with wariness, and the language in which the statute is couched shows that his supremacy might be reconciled with the papal authority, if the jurisdiction of that power were only of a spiritual nature. But by the statutes of later years, the revolution in church government had been consummated in England. The ancient doctrine of the Roman Catholic faith was acknowledged; but the king was placed as a sort of lay patriarch at the head of the ecclesiastical establishment. Thomas Cromwell, who had now become Henry's chief minister (see CROMWELL, THOMAS), was at this time raised to the new office of the king's vicegerent, and empowered to send commissioners into the several counties of England to inspect the monasteries, and to report, with rigorous exactness, the conduct and deportment of such as were found there This appointment, which had been made between the parliaments of 1536 and 1539, was confirmed by the recognition of the latter; and it was provided that the vicegerent should take his seat in the House of Peers before the Archbishop of Canterbury, and be ranked above all temporal lords, except some branches of the royal family. The first experiment which Cromwell made of his unlimited power was the gradual suppression of the various classes of religious houses, and the seizure of their possessions, at that time amounting to a large proportion of the landed property of the kingdom. This seizure of vested territorial possessions was, in a legal point of view, direct spoliation. But it was urged, on the other hand, that from the immorality, ignorance, and indolence in which those who enjoyed them indulged, they had forfeited their right, and might lawfully be deprived of these. By the inspectors of the religious houses, the public were informed of the existence of monstrous disorders in these communities. In 1536 the lesser monasteries were suppressed, amounting to nearly four hundred. Their revenues, computed at L.30,000 per annum, were confiscated to the king's use, besides their plate and other goods, estimated at L.100,000 more. The confiscation, however, was most unpopular, especially in those places where the ancient faith retained most sway, and occasional revolts broke out. Such a sweeping calamity must have brought ruin upon many innocent and even worthy and deserving persons. The spectacle of individuals, invested with the most sacred of all functions, expelled from their only habitations, where they had probably grown old, and were now unfit for bodily toil, was calculated to awaken feelings of sympathy for the sufferers, and probably of detestation for those who had driven them forth to perish in the wilderness. A disturbance broke out in Lincolnshire, where the first visitation of religious houses took place. But in the north a more serious affair, amounting to an insurrection, occurred. Between the Humber and the Tweed the people had rushed to arms, and they were joined by the inhabitants of Cumberland, Westmoreland, and a portion of Lancashire. This formidable body was led into the field by Robert Ask, a man of Yorkshire, and was preceded by priests bearing banners emblazoned with paintings of the sufferings of Christ. Several important towns fell into their hands; but the king met them with a superior force, which arrested their progress. They, however, succeeded in obtaining a general pardon, and then dispersed.

History. 1537.

A second visitation of the monasteries took place shortly afterwards. Various circumstances had occurred to exasperate Henry against the Catholic clergy; and the alarming revolts, at which priests had presided, and principally instigated the people by their inflammatory addresses, were of a nature to inflame such a combustible temper as his. In this second spoliation, the richest and most revered shrines were pillaged and destroyed, and the sacred relics, objects of so much superstitious veneration, were held up to the derision of the public. Various historians have enumerated a great number of these, and some of them are certainly calculated to excite surprise at the depth of that superstitious feeling which could induce a people to believe that the parings of St Edmund's toes, or the felt of St Thomas of Lancaster, or the shirt of St Thomas of Canterbury, were infallible recipes for certain disorders. On this occasion the shrine of the latter saint was demolished, and the wealth which it yielded was enormous. These shrines were pillaged, on the allegation, too often true, that they were the scenes of imposture, where miracles were pretended to be wrought. The king, on the whole, suppressed upwards of six hundred monasteries, above two thousand chantries and free chapels, and about two hundred colleges and hospitals. The confiscation was closed by a statute passed in 1539, which provided that "all monasteries, and other religious houses, dissolved, suppressed, surrendered, renounced, relinquished, forfeited, or by any means come to his highness, shall be vested in him, his heirs and successors, for ever." It must be owned, that although great abuses may have been detected, revenue not reformation, plunder not punishment, were the objects which the visitors had in view. With respect to the important question regarding property, involved in this measure, we shall avail ourselves of the remarks of Sir James Mackintosh on the subject.

"Thus was completed the confiscation of a fifth or a fourth part of the landed property of England and Wales within the space of five years. It may be a fit moment therefore to pause here, in order calmly and shortly to review some of the weighty questions which were involved in this measure. There is no need of animadverting upon the means by which it was effected, though we must assent to the affirmation of a great man, 'that an end which has no means but such as are bad, is a bad end.' But the general question may be best considered, keeping out of view any of those attendant misdeeds which excite a very honest indignation, but which disturb the operation of the judgment. Property is legal possession. Whoever exercises a certain portion of power over any outward thing in a manner which, by the laws of the country, entitles him to an exclusive enjoyment of it, is deemed a proprietor. But property, which is generally deemed to be the incentive to industry, the guardian of order, the preserver of internal quiet, the channel of friendly intercourse between men and nations, and, in a higher point of view, as affording leisure for the pursuit of knowledge, means for the exercise of generosity, occasions for the returns of gratitude; as being one of the ties which join succeeding generations, strengthening domestic discipline, and keeping up the affections of the kindred; above all, because it is the principle to which all men adapt their plans of life, and on the faith of whose permanency every human action is performed; is an institution of so high and transcendent a nature, that every government which does not

---

serves, "I cannot find any proof that it was ever published at all." Sir James Mackintosh is silent upon the point. Mr Turner, in his *History of the Reign of Henry VIII.* says, that in 1538 "it was given unblushingly to the world. This last order recites, that it had been suspended for three years on the persuasion of some princes. Cherubini, 623." In order to reconcile these conflicting statements, it may perhaps be supposed that it never was "published at all" in England, although it may have been "given unblushingly to the world" in other countries.

protect it, nay, that does not rigorously punish its infraction, must be guilty of a violation of the first duties of just rulers. The common feelings of human nature have applied to it the epithets of sacred and inviolable. Property varies in the extent of the powers which it confers, according to the various laws of different states. Its duration, its descent, its acquisition, its alienation, depend solely upon these laws. But all laws consider what is held or transmitted agreeably to their rules as alike possessing the character of inviolable sacredness. There may be, and there is, property for a term of years, for life, or for ever. It may be absolute as to the exercise of the proprietor's rights, or it may be conditional, or, in other words, held only as long as certain conditions are performed. There are specimens of all these sorts of property in the codes of most civilized nations. But in all these cases the essence of property is preserved, which consists in such a share or kind of power as the laws confer. The advantages may be extremely unequal. The inviolable right must, by the force of the terms, continue perfectly equal.

"The legal limits of the authority of the supreme legislature are not a reasonable object of inquiry, nor indeed an intelligible form of expression. But to conclude that, because the law may in some cases be said to create property, the law is to be deemed on that account as entitled rightfully to take it away, is a proposition founded on a gross confusion of two very distinguishable conceptions. It uses the word property in the premises for a system of rules, and in the conclusion for a portion of external nature, of which the dominion is acquired by the observance of these rules. It is only in the first of these senses that property can be truly called the creature of law. In the second sense it is acquired or transmitted, not by law, but by the acts of a man, when the acts are conformable to legal rules. It is impossible within our present limits to canvass the small or apparent objections which may occur to this scheme of reasoning. It is sufficient, perhaps, here to remark, that these are the generally acknowledged principles, and that deviations from them in practice are no more than partial irregularities, to which the disturbing forces of passion and interest expose human society.

"The clergy, though for brevity sometimes called a corporation, were rather an order in the state composed of many corporations. Their share of the national wealth was immense, consisting of land devised by pious men, and of a tenth part of the produce of the soil set apart by the customary law of Europe, for the support of the parochial clergy. Each clergyman had only in this case an estate for life, to which, during its continuance, the essential attribute of inviolable possession was as firmly annexed by law as if it had been perpetual. The corporate body was supposed to endure till it was abolished in some of the forms previously and specially provided for by law.

"For one case, however, of considerable perplexity there was neither law nor precedent to light the way. Whenever the supreme power deemed itself bound to change the established church, or even materially to alter the distribution of its revenues, a question necessarily arose concerning the moral boundaries of legislative authority in such cases. It was not, indeed, about a legal boundary; for no specific limit can be assigned to its right of exacting obedience within the national territory. The question was, what governments could do morally and righteously, what it is right for them to do, and what they would be enjoined to do by a just superior, if such a personage could be found among their fellow-men. At first it may seem that the lands should be restored to the heirs of the original grantor. But no provision for such a reversion was made in the grant; no expectation of its occurrence was entertained by their descendants; no habit or plan of life had been formed on the probability of it. The grantors or founders had left their property to certain bodies under the guardian power of the commonwealth, without the reserve of any remainder to those who, after the lapse of centuries, might prove themselves to be their representatives. It is a case not very dissimilar to that of an individual who died without discoverable heirs, and whose property for that reason falls to the state. It appeared, therefore, meet and righteous that in this new case, after the expiration of the estates for life, the property granted for a purpose no longer deemed good or the best, should be applied by the legislature to other purposes which they considered as better. But the sacredness of the life estates is an essential condition of the justice of such measures. No man thinks an annuity for life less inviolable during his life, than a portion of land granted to him and to his heirs for ever. That estate might, indeed, be forfeited by a misperformance of duty; but perfect good faith is in such a case more indispensable than in most others. Fraud can convey no title; false pretences justify no acts. There were gross abuses in the monasteries; but it was not for their offences that the monastic communities fell. The most commendable application of their revenues would have been to purposes as like those for which they were granted as the changes in religious opinion would allow. These were religious instruction and learned education. Some faint efforts were made to apply part to the foundation of new bishoprics; but this was only to cover the profusion with which the produce of rapine was lavished on courtiers and noblemen, to purchase their support of the confiscations, and to ensure their zeal and that of their descendants against the restoration of popery.

"It is a melancholy truth, and may be considered by some as a considerable objection to the principles which have been thus shortly expounded, that if in 'the seizure of abbey lands' the life estates had been spared, the monks, who were the main stay of papal despotism, and the most deadly foes of all reform, would have had arms in their hands which might have rendered them irresistible. It must perhaps be acknowledged, that it was more necessary to the security of Henry's partial reformation to strip the monasteries at that moment, than to dissolve communities which a better regulation might in future reconcile to the new system.

"We are assured by Sir Thomas More, 'that in all the time while he was conversant with the court, of all the nobility of this land he found no more than seven that thought it right or reasonable to take away their possessions from the clergy.' So inconsiderable was the original number of those who, not many years after, accomplished an immense revolution in property.

"To which it must be answered, that the observance of justice is more necessary than security for any institution; that many regulations might have stood instead of one deed of rapine; that the milder expedients would have provoked fewer and more reconcilable enemies; that if, on the whole, they afford less security, the legislature were at least bound to try all means before they who were appointed to be the guardians of right set the example of so great a wrong. Rulers can never render so lasting a service to a people as by the example, in a time of danger, of justice to formidable enemies, and of mercy to obnoxious delinquents. These are glorious examples, for which much is to be hazarded."

Henry had now so far separated himself from the communion of Rome, that it became in some measure necessary for him to concoct a creed of his own. The

History. 1539.

clergy were divided into two factions, denominated the men of the old and the new learning. The chief of the former was Gardiner bishop of Winchester, who was supported by Lee archbishop of York; Stokesly bishop of London, Tunstall of Durham, and Clarke of Bath and Wells. The latter acknowledged as leaders, Cranmer archbishop of Canterbury, Haxton of Sarum, Latimer of Worcester, and Fox of Hereford. These could depend on the powerful interest of Cromwell the vicar-general, and of Audley the lord chancellor; those on that of the duke of Norfolk, and of Wriothesley the premier-secretary. Various long debates took place upon the new creed, but it was neither completed nor sufficiently fenced round with suitable penalties, till an act was passed by the parliament, which sat in April 1539, entitled " an act for abolishing diversity of opinions." This convocation was opened by the chancellor informing the House of Lords that it was his majesty's earnest desire to extirpate from his kingdom all diversity of opinions with regard to religion; and as this enterprise was, he owned, difficult and important, he desired them to choose a committee from amongst themselves, who might frame certain articles, and communicate these afterwards to parliament. The lords named the vicar-general Cromwell, now created a peer; the Archbishops of Canterbury and York; and the Bishops of Durham, Carlisle, Worcester, Bath and Wells, Bangor, and Ely. But this small committee itself was agitated with such diversity of opinions that it could come to no conclusion. The Duke of Norfolk then moved, that since there was no hope of having a report from the committee, the articles of faith proposed to be established should be reduced to six, and a new committee be appointed to frame an act respecting them. As this peer was understood to speak the king's mind, his motion was immediately complied with; and, after a short prorogation, the bill of the six articles was introduced, and, having passed the two houses, received the king's assent. By this law the doctrine of the real presence was established, the communion in one kind, the perpetual obligation of vows of chastity, the utility of private masses, the celibacy of the clergy, and lastly, the necessity of auricular confession. The denial of the real presence was punishable with death by fire, and the same forfeiture as in cases of treason, and admitted not the privilege of abjuring; an unheard of cruelty, unknown even to the inquisition itself. The denial of any of the other articles, even though afterwards recanted, was punishable by the forfeiture of goods and chattels, nd imprisonment during the king's pleasure. An obstinate adherence to error, or a relapse, was adjudged to be felony, and subjected the delinquent to death. The marriage of priests was punished in the same manner. Their commerce with women was, for the first offence, forfeiture and imprisonment; and for the second, death. Abstaining from confession, and from receiving the eucharist at the accustomed times, subjected the person to fine, and to imprisonment during the king's pleasure; and if the criminal persevered after conviction, he was to suffer death and forfeiture, as in cases of felony. Commissioners were to be appointed by the king for inquiring into these heresies and irregular practices, and the criminals were to be tried by a jury.

Henry had now been a widower for above two years. In 1537 Jane Seymour, his third queen, had born him a son, afterwards Edward VI.; but she herself expired in less than a fortnight afterwards. The king afterwards made proposals of marriage to several foreign princesses, and others, without success. Under these repeated disappointments, he readily listened to the suggestions of Cromwell, who proposed to him Anne, sister of the Duke of Cleves, a considerable prince on the Lower Rhine, who had lately established Lutheranism in his principality. This choice showed the leaning of his secretary's mind, and the progress of men in general towards reformation. Henry had seen a painting by Holbein of this lady. The artist had invested her with fictitious charms, which captivated the sensual monarch, and inspired him with such eagerness to behold her, that he proceeded to Dover, where she was to disembark, his mind no doubt swelling with pleasing anticipations. But he was miserably disappointed, and could not conceal his chagrin. She was indeed of the standard dimensions, being large and tall as his heart could desire; for stature had now become an indispensable qualification in the individual who should aspire to gain the affections of the king of England. Without entering into the disgusting particulars connected with his marriage with Anne of Cleves, it is sufficient to state that the nuptials were solemnized, and that the lady was treated, not as a wife, but as a friend. The distress of Henry was great, and at last drew the attention of the House of Lords to the subject on the 6th of July 1540. These obsequious peers entreated him to make inquiry into the validity of his marriage with the Lady Anne of Cleves; and the Commons having concurred with them, the king granted their prayer. Of course this drama was all arranged, and the characters cast, some days before the meeting of parliament. The convocation appointed to examine into the matter declared the marriage to be null by the consent of Lady Anne herself, which was insured by the grant of an income of L.3000 annually; and the lady, it would appear, lived comfortably on her annuity for sixteen years in England. The bill for the nullity was passed by both houses, and received the royal assent on the 24th of July 1540. About a fortnight afterwards the king married his fourth wife, Catherine Howard, niece to the Duke of Norfolk. But let us look back upon the fate of Cromwell, who was instrumental in procuring the former union. It was indispensably necessary that the revolutions which took place in Henry VIII.'s palace and bed should in some way or another be marked with blood.

History. 1540.

The arrest, condemnation, and execution of Cromwell, is another of those cruel and tyrannical measures which have entailed accumulated odium upon the name of Henry VIII. A bill to attaint the vicar-general of high treason was brought into parliament in June 1540; and before the end of the month it had passed through both houses. He was charged with heresy because he had favoured the new doctrines, and with treason because he had performed several acts of royal authority without the warrant of the king. Cromwell was condemned unheard, and executed in about a month afterwards. This was an act of gross injustice, but it was far from being unpopular. The nobility were glad to be rid of an individual who had raised himself from the shop of a fuller to the highest offices of state; and the Roman Catholic party, who were the most numerous, and had regained much of their ascendency, rejoiced at the fall of one who was the active conductor of that system of confiscation which struck such a blow at their power in England. In that business he certainly must have connived at much rapine and robbery, which it was out of his power to prevent. He has also been charged with Machiavelian policy; but there is no satisfactory evidence that he was unfaithful to his sovereign. Like Wolsey, he seems to have served his king more faithfully than his God; and it is remarkable that he fell into his own snare, having repeatedly shown the example of attainder without trial.

At this period the act of the six articles was in the fullest vigour of its cruelty; and many iniquitous executions took place. One of the most horrid of these was that of Courtney marquis of Exeter, with Lord Montague and Sir Ed-

History. 1540.

ward Nevil. They were descended from Edward IV., and this seems to have constituted their only crime. Towards the close of 1538 they were first arrested and committed to the Tower; and shortly afterwards the Countess Margaret, the mother of the Poles, was also taken into custody. Exeter was charged with the offence of having conspired to raise Reginald Pole to the throne. This individual, best known as a cardinal, was the son of the above-named lady, who was daughter of the Duke of Clarence. Her son's life was principally passed in Italy, where he was much celebrated for his talents; and Henry appears to have been proud of him, for he munificently discharged his expenses. Their friendship, however, terminated with the king's divorce from Catherine, which the English monarch vainly besought Pole to sanction. The revenge of Henry, who seems now to have thought that without the shedding of blood there could be no remission of offences, fell upon the mother of the cardinal, and the last of the Plantagenets. She was attainted of high treason, and sent to prison, as above noticed. The noblemen committed about the same time were soon afterwards executed; but the lady lingered two years in confinement, and was at last conducted to the scaffold on the 27th of May 1541, where, to complete the horror of the transaction, from mismanagement on the part of the executioner, her neck was horribly mangled, and her grey hairs, clotted with blood, fell dishevelled over her face ere the bloody act was consummated.

To return to the domestic affairs of Henry, he had not been many months married to Catherine Howard before he received such information of her dissolute life before marriage as induced him to suspect that she might still continue it, and to cause a rigid inquiry to be made into her conduct. There was no doubt as to her vices previously to her union with the king; and some acts of infidelity after it were also brought home to her, but the details are too disgusting for human feelings. Cranmer was one of the individuals employed to communicate information to the king; and although there is no evidence that he was ever guilty of a malicious or vindictive act, yet he sometimes wanted the courage to resist crimes; and the slavish manner in which he, along with the rest of the ministers and parliament in general, bowed to the despotic will of the king, cannot be extenuated.

Two of Catherine's paramours were arrested, and confessed their crimes; and the queen herself acknowledged her guilt previously to the marriage, but denied having committed any act of infidelity subsequently thereto. This, however, was not believed; and on the 14th of February 1542 she was executed in the Tower, along with Lady Rochford, who in some way or another was implicated as an accomplice in the guilt of the queen.

To attaint without trial had now become fashionable; but to punish with death that which was not made criminal by any former statute, was altogether new. To countenance such severities as those which had lately taken place, it was enacted in the very bill of attainder, that every woman about to be married to the king or his successors, not being a maid, should disclose her unchastity to him, under the penalty of treason; that any person knowing the fact and not disclosing it, should be subject to the lesser penalty of misprision of treason; and that the commission of adultery by the queen or wife of the prince should be punishable with death.

These laws afforded some amusement to the people, who now said that the king must look out for a widow, as no reputed maid would be disposed to offer herself whilst such a dreadful statute was suspended over her head. This in reality took place, for on the 10th of July 1543 Henry espoused Catherine Parr, the widow of Lord Latimer, and a lady of mature age. She had read Lutheran books, and was inclined to support the doctrines of the reformers. She even went so far as to enter into controversy with her imperious lord, who valued himself not a little on his theological knowledge. He ordered Wriothesley and Gardiner to give orders for her imprisonment, and to prepare articles of impeachment against her. The third Catherine had very nearly been honoured with a place upon the list of victims which were sacrificed by this Blue Beard of the west, but she evaded the blow by her ingenuity and tact. During the remainder of her life, however, she never again ventured to provoke the vengeance of the royal polemic.

History. 1543.

As head of the church, the attention of the king was now principally turned to the management of its affairs. He enforced an observance of the six articles both by Protestants and Catholics, and any deviation from them was punished with tyrannical severity. He was very impartial in his distribution of what he called justice; and it was not uncommon for individuals professing opposite faiths to perish at the same stake. The Christian of those days had a difficult part to perform; for whilst the king renounced in one respeect the authority of the pope, he acknowledged it in another by his adherence to the doctrines of the church of Rome; so that it frequently happened that those who were against the head of it were burned, and those who were for him were hanged. In connection with church affairs, Henry effected a further dissolution of colleges, hospitals, and other foundations of that nature, with the spoils of which he enriched his treasury. He also extorted from many bishops a surrender of their chapter lands, and in this manner he succeeded in pillaging the sees of Canterbury, of York, and of London. Amongst the religious orders suppressed was that of the Knights of Malta, or, more properly, St John of Jerusalem. They obstinately refused to surrender along with the other monasteries who laid their rights at the feet of the king, and he was compelled to have recourse to parliament for the purpose of obtaining its authority for dissolving the order, which was very rich, and whose spoil was therefore precious in his sight.

For the purpose of maintaining a rigid purity in speculative principles, he nominated a commission of divines to make out a creed for the benefit of his subjects. In connection with this appointment a circumstance occurred which strongly marks the character of this reign, as well as of those who composed the council of the nation. Before the reverend conclave had made any progress in its arduous undertaking, the parliament passed a law which went to ratify all the tenets which the divines might establish in accordance with the king's consent. This clearly shows that the individuals composing that body, as well as the parliament, were merely ciphers, and that Henry was the initial unit which gave them value. A small volume was published under the title of *The Institution of a Christian Man*, which was made the infallible standard o. orthodoxy. But the king's inconsistency was as strikingly exemplified in his religion as in his morals. A new book was ordered to be composed, and three years were spent before it could be brought to that desirable state of perfection which the king wished. At length, however, it came forth under the title of *A necessary Doctrine and Erudition for any Christened Man;* and in order to distinguish it from the former work upon the same subject, it was called emphatically the king's book. It taught the same doctrines as the preceding compilation, with the addition of transubstantiation and the sufficiency of communion under one kind. The new creed was generally approved of, and all writings in opposition to it were prohibited. From the period of the publication of the "king's

History. 1543. book" until the accession of the next sovereign, it continued to be the only authorized standard of English orthodoxy. Henry had formerly sanctioned the publication of the Bible in English, and permission was granted to all his subjects to peruse it. But he afterwards retracted the liberty which he had vouchsafed them, and prohibited the reading of the Scriptures by the lower orders of the people under the penalty of imprisonment. The mass book was also examined, and some alterations were made upon it.

But to return to the political affairs of the nation; in the beginning of the year 1543 Henry renewed his friendship with the emperor, which had been suspended by the divorce question. They concluded an alliance against Francis; and on the 14th of July 1544 Henry crossed the seas in a ship furnished with sails of cloth of gold. The principal event of this war was the surrender of Boulogne, into which the English monarch made a triumphant entry on the 18th of September. But he shortly afterwards returned to England. On the 7th of June 1546 hostilities were concluded by a treaty, of which the principal stipulation was, that within eight years Henry should receive two millions of crowns, with arrears and costs, which are enumerated; and, on payment of these sums, Boulogne and its dependencies were to be restored to Francis. Henry's warlike propensities were also exercised in reference to Scotland and Ireland; but peace was finally restored after both countries had suffered considerably, especially the former. These wars, however, exhausted the treasury of the English monarch. He was compelled to extort money from parliament in his usual manner, and also to depreciate the coinage of the realm, which he had not scrupled to do before.

The cruelty of Henry continued conspicuous to the very close of his life. Disease made dreadful ravages upon his worn-out and unwieldy frame, so that he had to be moved from place to place by machines contrived for the purpose; yet even these unequivocal tokens of approaching dissolution had no effect in subduing the vindictive spirit or humanising the mind of the sufferer. It was in this pitiable state that he perpetrated an act which has become memorable from the fame of the illustrious victim. This was the execution of Henry Howard, earl of Surrey, so justly renowned for his poetical genius. There had for some time existed a spirit of rivalry between the Seymours and the house of Howard. The Duke of Norfolk was indignant at the ascendency of the former in the royal favour; and his son, the Earl of Surrey, could not forgive the Earl of Hertford, a member of the other family, for having superseded him in the command of the garrison of Boulogne; he had also been heard to predicate that the time of revenge was not far distant. The house of Howard alone stood in the way of the Seymours in the pursuit of their aggrandisement under the approaching minority; and they accordingly employed every means of drawing down the vengeance of the king upon their heads. Norfolk and Surrey were accordingly committed to the Tower on the 12th of December 1546. Surrey was tried on the 13th of January following, on a charge of having quartered on his shield the arms of Edward the Confessor. He vainly defended himself with his usual eloquence and spirit, and showed that he had worn the arms fourteen years without giving offence, and that they had been assigned to him by a decision of the heralds. But the fact being admitted, it was taken as sufficient evidence that he aspired to the throne, and the jury condemned him to suffer death. About a week after the sentence was pronounced, this gallant and accomplished nobleman expired upon the scaffold. His father was also tried and condemned to perish in the same manner on the 29th of January. But on the morning of the 28th the spirit of Henry VIII. followed that of Surrey to the judgment-seat; and Norfolk, after remaining in prison for several years, was at length set at liberty. History. 1547.

Henry VIII. is one of the most repulsive sovereigns to be met with in the list of English kings. There is a gross brutality about the man, and a remorseless tyranny and blood-thirstiness about the king, which totally obscure any human features which his character may have possessed. Some of his crimes are of so dark a dye, and so peculiarly diabolical, as to make the mind shudder at the very mention of his name. It is difficult to extend charity to, or rank with ordinary humanity, one who could repeatedly hurry from his arms to the scaffold those whom he had loved and embraced with passionate tenderness, if such language may be used in reference to any feeling which animated the breast of such a barbarian. It was after the fall of Wolsey that the prominent features of Henry's moral deformity fully developed themselves; and they are such as have attached to his name a degradation which can neither be removed nor palliated. For the good which he was the means of doing, in sanctioning a reformation in the affairs of the church, he deserves no credit; for it originated in a spirit of vindictive revenge, and was perpetuated by plunder and cruelty. Henry was not destitute of ability; and the esteem which we may infer he entertained for literature, since he patronised learning, is one of the few traits of his character which are not repulsive and odious.

Henry was succeeded by his only son Edward, a boy of nine years of age. He was proclaimed king of England on the 31st of January 1547, and crowned in the month following. The most remarkable transactions of his reign are those connected with religion. The restraint which Henry VIII. had laid upon the Protestants was now taken off; and they not only maintained their doctrines openly, but soon became the prevailing party. Henry had fixed the majority of his son at eighteen years of age; and, in the mean time, appointed sixteen executors of his will, to whom, during the minority, he entrusted the government of the king and kingdom. But the first act of the executors was to choose the Earl of Hertford, afterwards Duke of Somerset, protector of the realm; and in him was lodged all the regal power, together with a privilege of naming his own privy council.

The Duke of Somerset had long been numbered amongst the secret partisans of the reformers; and, immediately on his elevation to his high dignity, he began to express his intention of reforming the abuses of the ancient religion. Under his direction and that of Cranmer, therefore, the reformation was vigorously carried forward; persecutions under the act of the six articles ceased, prisoners were released, and exiles were recalled. Homilies were composed by Cranmer, and ordered to be read by parish priests to their congregations. Visitors were appointed to inspect ecclesiastical establishments, and see that four sermons were yearly preached against the papal authority; that the worship of images should be denounced, and those who were the objects of pilgrimages and offerings should be destroyed; that the English Bible, with Erasmus's commentary on the gospels, should be placed in every church for the use of the people; together with many other points, which, without being very important in themselves, were calculated to assure the people that the government was no longer neutral in matters of religion. The principal person who opposed these innovations was Gardiner bishop of Winchester; a man of great learning, abilities, and resolution, but one of Henry's devoted agents in the suit for a divorce from Catherine, his first queen. He made a manly and becoming resistance to these injunctions, from principles of civil liberty, as much as of ecclesi-

History. 1547. astical discipline. To the disgrace of their own principles, the reformers now displayed as virulent a spirit of persecution as the Catholics had formerly done. Gardiner was committed to the Fleet prison, where he was treated with great severity. He was afterwards sent to the Tower; and having continued there two years, he was commanded to subscribe several articles, amongst which was one confessing the justice of his own imprisonment. To all the articles but this he agreed to subscribe; but that did not give satisfaction. He was then committed to close custody; his books and papers were seized; all company was denied him; and he was not even permitted the use of writing materials. Bonner of London, more violent and more subservient, escaped protracted imprisonment by obsequious submission. Several bishops also screened themselves by sacrificing a considerable share of their revenues; others were deprived of their offices; and Tunstal bishop of Durham, an eminent prelate, was ejected from the privy council, in order to impress on the people by a strong example the disinclination of the protector to the ancient faith. In November 1547 a parliament was assembled, in which several bills were passed to promote and enlarge the reformation. The communion was appointed to be received in both kinds by the laity as well as by the clergy, without condemning the usages of other churches. Bishops were to be nominated by the king, and process was to run in the king's name in ecclesiastical courts. The statutes against the Lollards were repealed, as well as all the acts of Henry VIII. upon religious matters, excepting those directed against the supremacy of the pope; and other acts relating to civil affairs were also abrogated. In the next session uniformity in public worship was established, in which the use of the book of common prayer, as prepared by the primate and his brethren, was enjoined. This composition is the foundation of that which, having undergone various alterations in subsequent reigns, continues in use at the present day. By one law the observance of fast days and of Lent was enjoined under penalties; and by another the English clergy were emancipated from compulsory celibacy.

The rest of this reign presents little but the history of the intrigues and cabals of courtiers. There was a war with Scotland, which began with injustice and was conducted with inhumanity. Insurrections also took place in Ireland, where the reformation made no progress. The details of these transactions will be given in the articles SCOTLAND and IRELAND. The protector was first opposed by his own brother Admiral Sir Thomas Seymour, who had married Catherine Parr, the late king's widow. She died soon after the marriage; and the widower is said to have then paid his addresses to the Princess Elizabeth. His brother the duke, who was at that time in the north, being informed of his ambitious projects, speedily returned, had him attainted of high treason, and at last condemned and executed. The Duke of Somerset himself, however, became unpopular, and a powerful confederacy was formed against him, at the head of which was Dudley earl of Warwick. This nobleman succeeded in overthrowing the power of the protector, and getting him committed to prison on the 13th of October 1549, whilst he himself was installed in the office of lord high admiral. In the month of February following Somerset was released upon payment of a fine and ransom; but towards the end of 1551 he was again sent to the Tower, tried for high treason and felony, and condemned. He was acquitted of the first charge, but not of the second, as he ought to have been. He suffered upon the scaffold on the 22d of January 1552. Warwick, now duke of Northumberland, had thus the reins of government entirely at his own disposal. Not satisfied with the office of protector, he aimed at altering the succession, and placing the crown upon the head of his son. He represented to Edward, who was now in a declining state of health, that his sisters Mary and Elizabeth, who were appointed by Henry's will to succeed to the crown, in failure of direct heirs, had both been declared illegitimate by parliament; that the queen of Scots, his aunt, stood excluded by the king's will; and being also an alien, lost all right of succeeding. The three princesses being thus excluded, the succession naturally devolved upon the Marchioness of Dorset, eldest daughter of the French queen, Henry's sister, who had married the Earl of Suffolk after her first husband's death. The next heir to the marchioness was Lady Jane Grey, the wife of Northumberland's fourth son, Lord Guildford Dudley. The king, who was accustomed to submit to the politic views of this minister, agreed to have the succession altered, and sketched with his own hand a draft of the new destination of the crown, which was submitted to a council. The judges, however, were far from acquiescing in the proposal contained in this instrument; and they hesitated to sign it, because it would subject those who had drawn and those who had advised it to the penalties of treason. Their hesitation excited the rage of Northumberland, who threatened them with his authority, and, pronouncing them traitors, declared that he would fight in his shirt with any man in so just a cause as that of Lady Jane's succession. A new paper was drawn up, by which the judges were screened from any consequences which might have resulted from their signing of it. By the new patent for changing the succession, the princesses Mary and Elizabeth were set aside, and the crown settled upon the heirs of the Duchess of Suffolk, who was contented to forego her own claim.

History. 1553. For some time the king had languished under a pulmonary complaint, and symptoms of an advanced stage of consumption began to make their appearance. After the settlement of the crown, his health visibly declined every day, and little hopes were entertained of his recovery. The deathbed devotions of Edward bear testimony to his love for his subjects, and his zeal for what he believed to be the purest form of Christianity. "O Lord, save thy chosen people of England, defend this realm from papistry, and maintain thy true religion." Such is a specimen of the supplications which this pious and short-lived prince breathed forth. On the 6th of July 1553, Edward, being then in the sixteenth year of his age and seventh of his reign, breathed his last. Whilst he filled the throne of England, no Roman Catholic had suffered death on account of his religion. By his gentleness and docility he was indisposed to shed blood, and, on the whole, his reign was more free from religious persecution than any administration of the same length, in any great country of Europe, since the rise of protestantism. In abilities he was equal, probably superior, to most boys of his years; but the flattering praises lavished upon him by his panegyrists are to be received with abatements. It was his dying wish that Lady Jane Grey, the companion of his infancy, should be his successor.

The death of Edward was carefully concealed for two days; but on the 8th of July the event was communicated to the ambassadors, and the civic functionaries of London were ordered to make preparations for the coronation of Lady Jane Grey. The intelligence was transmitted to Mary by her friends at court, and on the 9th she wrote a letter to the privy council, expostulating with them upon their conduct; and, solemnly affirming her right, she tendered a pardon to them if they would order her immediate proclamation. The council, however, adhered to the interests of Jane, and both parties prepared to decide the contest by an appeal to arms.

History. 1553.

When Edward's death, and her own elevation to the throne, were announced to Lady Jane, she was thrown into a state of great agitation. The manner in which she was affected will be best understood from a passage in a letter of hers which she afterwards transmitted to Mary. "As soon as I had, with infinite pain to my mind, understood these things, how much I remained beside myself, stunned and agitated, I leave to those lords to testify who saw me fall to the ground, and who knew how grievously I wept." She urged the preferable claim of the princesses to inherit; but being pressed by the authority of the judges, she at length consented to accept of the royal dignity. She suffered herself to be conveyed to the Tower, and on the same day the heralds proclaimed the death of Edward and the succession of Jane. Mary was also proclaimed at Norwich, and it is somewhat singular that the populace took no interest in either of the proclamations. No shouts of applause or outward demonstrations of joy followed the announcement of the choice of a new sovereign. Northumberland was unpopular, a great part of the Protestants cooperated with the Catholic partisans of Mary, who were numerous and powerful; and the protector, by his supineness, allowed them to assemble in great force at Framlingham Castle, in Suffolk, where the princess had fixed her residence. Northumberland became alarmed, and although he had assembled a considerable army, his heart failed him when he saw the demonstrations which were made by the people in favour of Mary. He had taken the field in person, which was a fatal step; for his absence afforded an opportunity to the adherents of Mary who were in the council to make arrangements for exalting her to the royal dignity. It is sufficient to observe that they effected their purpose. Mary was proclaimed, and Jane, after a ten days reign, resigned the crown with a great deal more satisfaction than she had accepted of it. Northumberland had been compelled to proclaim Mary at Cambridge; but this did not prevent him from being led a prisoner to the Tower, which had lately been his palace.

Mary, accompanied by her sister Elizabeth, made her triumphal entry into London on the 3d of August 1553. Her attentions were first turned towards those who had suffered in her cause. She released several prisoners from the Tower, amongst whom were the aged Duke of Norfolk, and her kinsman Edward Courtenay, whom she soon afterwards created Earl of Devonshire. On the 18th of August the Duke of Northumberland, the Marquis of Northampton, and the Earl of Warwick, were tried for high treason; and on the following day Sir John Gates, Sir Henry Gates, Sir Andrew Dudley, and Sir Thomas Palmer, were tried for the same offence. Of the culprits who were condemned, three were selected for execution, Northumberland, Sir John Gates, and Sir Thomas Palmer, who suffered upon the scaffold on the 22d of August.

The mind of Mary now became solicitous about the affairs of religion. All the deprived Catholic bishops were restored. The acknowledged abilities of Gardiner soon raised him to the post of prime minister. He early received the custody of the seals, and not long afterwards he was appointed chancellor. The Protestant bishops, in the eyes of their Roman Catholic brethren, had incurred deprivation by marriage, or still more severe penalties by preaching heresy. On the 2d of September Cranmer was committed to the Tower, and on the 13th Latimer followed him into the same captivity. The latter, in point of moral heroism, was the antipodes of Cranmer, who was gentle and kind, timid and pliant. Latimer was brave, sincere, and inflexible. As he passed through Smithfield on his way to the Tower, he remarked, "Smithfield has long groaned for me." By an early proclamation Mary had declared that "she could not hide her religion, but that she mindeth not to compel any of her said subjects thereunto, until such time as a farther order by common consent shall be taken therein." The "farther order" did take place, although not in accordance with "common consent." On the 5th of October 1553, parliament assembled, and, in a session of nineteen days, passed only three acts; one for the abolition of all the treasons and felonies of Henry VIII.; another for the restoration in blood of Gertrude marchioness of Exeter; and a third for the like restitution of that lady's son, Edward Courtenay, now Earl of Devonshire. But on the 24th of the same month, several important acts were passed, by which the road was paved for the re-introduction of the Roman Catholic faith as the creed sanctioned by royalty. By these acts Henry's divorce was declared void, and his first marriage pronounced valid; so that the claim of Elizabeth, on whom the Protestants had fixed their eyes with anxious hope, was virtually set aside. But the progress of the revolution in religious matters was slow; and before the perfect re-union with the Church of Rome was consummated, several events of considerable importance took place. Mary having been crowned at Westminster with the usual solemnity on the last day of September 1553, it now became the interest of the Catholic party to obtain a suitable marriage for her. Of natives only two were proposed to her choice, both descended from the house of York; these were Cardinal Pole, and Edward Courtenay, the individual whom she had released from confinement. But the Emperor Charles having heard of Mary's intention to choose a husband, proposed his son Don Philip. This Spanish match was so broad and decisive a step towards Rome, that the House of Commons took the alarm, and presented an address to the queen, in order to dissuade her from her purpose. She returned a haughty answer; and on the 30th of October, having conducted the imperial minister into her private oratory, she there solemnly called God to witness that she plighted her troth to Philip prince of Castille. To obviate all clamour, the articles of marriage were drawn up as favourably as possible for the interests of England. It was agreed that though Philip should have the title of king, the administration should be entirely in the queen; that no foreigner should be capable of holding any office in the kingdom, nor should any innovation be made in the laws, the customs, and the privileges of the people; and that Philip should not carry the queen abroad without her consent, or any of her children without the consent of the nobility. Sixty thousand pounds a year were to be settled upon her as a jointure, and the male issue of this marriage were to inherit Burgundy and the Low Countries as well as the crown of England; and in the event of the death of Don Carlos, Philip's son by his former marriage, without any heir, the queen's issue were also to inherit the rest of the Spanish dominions.

All these concessions, however, were not sufficient to quiet the apprehensions of the people. They were considered merely as words of course, which might be retracted at pleasure; and the nation murmured loudly against a transaction so dangerous to its ancient liberty and independence. The Duke of Suffolk, a zealous Protestant, attempted to excite his tenants in Warwickshire to revolt; but with little success. His followers were routed by Lord Huntingdon, and he himself was betrayed into the hands of his enemies. An insurrection was also raised by Sir Thomas Wyatt, a Roman Catholic, at the head of four thousand men, who set out from Kent to London, publishing a declaration against the Spanish match and the queen's evil counsellors. Having advanced as far as Southwark, he required that the queen should put the Tower of London into his hands; that she should

History. 1553.

deliver four counsellors as hostages; and that, in order to ensure the liberty of the nation, she should marry an Englishman. But his force was still by far too inconsiderable to support such magnificent pretensions, although it was afterwards augmented to fifteen thousand men; and he unluckily wasted so much time without attempting any thing of importance, that the popular ferment entirely subsided, his followers gradually abandoned him, and he was at last obliged to surrender himself near Temple-Bar to Sir Maurice Berkeley, who committed him to the Tower, where, in a short time, he was joined by the chief of the surviving conspirators. The nobility and gentry immediately repaired to St James's to congratulate the queen on the suppression of the rebellion. But two were excepted; Courtenay duke of Devonshire, and the young Earl of Worcester, who, on the first approach of the enemy, had turned their horses' heads and fled. On the 3d of November 1553, Lord Guildford Dudley and Lady Jane Grey had been convicted of high treason. Lady Jane and her husband were both only in their seventeenth year, and no time was fixed upon for their execution; but the revolt of Suffolk, Lady Jane's father, proved an incentive sufficiently strong to prevail over the slender pity of bigots and politicians, and the sacrifice was consummated.

On the 8th of February Mary signed a warrant for their execution, and on the 12th of the same month it was put in force. Lord Guildford Dudley had requested an interview with his beloved wife, who, however, declined the meeting, justly fearing that it might unfit them for the dreadful scene through which they were about to pass. She saw him issue through the gate of the Tower to the scaffold; and soon afterwards, in chancing to look from the same window, she saw the bloody carcass, half covered in the vehicle which bore it back from the place where vengeance and injustice, disguised under the name of law, had done their worst. Lord Dudley was beheaded on Tower-Hill; but his wife, on account of her royal descent, was spared the ignominy of a public execution. Lady Jane Grey is celebrated as exhibiting a matchless union of beauty with genius, and learning with virtue and piety. She astonished the learned of Europe by her talents and accomplishments, and will be recognised by all posterity as one of the purest and most amiable of historical characters. Were Mary chargeable with no other atrocity than that of putting Lady Jane to death for the crime of a father (for it was on his account that the daughter suffered), it were quite sufficient to cover her memory with irremoveable degradation. "It was a death," says Sir James Mackintosh, "sufficient to honour and dishonour an age." Suffolk, her father, perished in the same manner a few days afterwards. Sir Nicholas Throgmorton was tried, but the defence which he made was found so good in law, that the jury acquitted him. Above sixty others of the conspirators were condemned to the block, amongst whom were Lord Thomas Grey the brother of Suffolk, and Wyatt the principal mover of the rebellion.

This revolt had very nearly proved fatal to the Princess Elizabeth, who for some time had experienced harsh treatment at the hands of her sister. Mary, upon whom the mantle of Henry VIII. had descended, felt antipathy to her on account of the quarrel between their mothers. This circumstance, in the mind of one whose tender mercies were cruel, was sufficient to change the milk of sisterly affection into mortal venom; and a favourable opportunity was only necessary to make her feel its deadly effects. Nearly a month was spent in labouring to extract information against Elizabeth from Wyatt whilst he lay in prison. But the unfortunate gentleman honourably acquitted her, although he might, in all probability, have saved his own life by implicating her in the late rebellion. At Ashridge, whither she had retired to escape the constrained participation in a worship which she disapproved, overtures had been made to her by the chiefs of the revolters; but her acceptance or consent was neither shown nor seriously alleged. Immediately after Wyatt's discomfiture, she was conducted to London in a very infirm state of health. It was doubted whether she would reach her destination alive; but youth and strength triumphed over the malady with which she was affected. Courtenay earl of Devonshire was also arrested, and committed to the Tower. Two councils were held on the fate of Elizabeth, and the judges were divided in their opinions as to her guilt. Gardiner, although he professed to think Elizabeth deserving of death, yet considered her confinement at Ashridge, and Courtenay's residence at St James's, as irreconcilable with a just conviction of treason. The head and front of her offending seems to have been misprision, or concealment of projects of revolt, which was now not a capital crime. It was fortunate for Elizabeth that one of the first measures of her sister, when she ascended the throne, was to sweep away the odious heap of treasons raised up by her father, and the punishment of misprision with death was one of them. But Elizabeth, although absolved from a capital charge, was nevertheless committed to the Tower; and shortly afterwards she was put under the charge of Sir Henry Bedingfield, keeper of Woodstock. During her stay in the Tower, the princess had no other expectation than that of mounting the scaffold which had been trodden long before by her unhappy mother, at her father's stern behest, and on which the blood of Lady Jane Grey, the purest of the pure, was scarcely dry. When Bedingfield came with his soldiers to conduct her to Woodstock, she asked, with her usual quickness and poignancy, "Is the scaffold of Lady Janet taken away?" A few days later, Courtenay was transferred from the Tower to Fotheringay Castle.

History. 1554.

The rebellion had suspended for some weeks the proceedings relative to the queen's marriage. But in the beginning of March the English ambassador returned from the Continent with the ratification of the treaty; and Philip landed at Southampton on the 19th of July 1554, attended by a magnificent train of Spanish grandees and Burgundian lords. The marriage between him and Mary was solemnized by Gardiner in his cathedral at Winchester, before crowds of noblemen from all parts of Christendom, and with a pomp and splendour seldom surpassed. Philip was then in the twenty-ninth year of his age, and Mary in her thirty-eighth year. The countenance and form of the prince were far from being disagreeable; but the stately reserve of his Spanish manners was not calculated to lessen the repugnance of the English people to the union.

Soon after her marriage, Mary resolved to restore the religious polity of the kingdom to that state in which it had existed at the time of her birth. Accordingly, on the 12th of November a parliament was holden for this purpose, and a bill passed both houses "for the restitution in blood of the Lord Cardinal Pole." But a difficulty arose regarding the abbey lands; for it was feared that those who possessed them in spite of the indelible claims of the church might be called before the tribunal of the pious cardinal. However, on the 20th of November, Pole arrived at Dover, armed apparently with ample powers to do every thing necessary for the reconciliation of England with the church of Rome; and amongst these was full authority to do with the abbey lands as he thought fit. Nine days after his arrival, he made an oration to the two houses, exhorting them to return to the bosom of the universal church, at the same time absolving the kingdom from the papal in-

History. 1554.

terdict. The request was formally acceded to, and Pole was enabled to announce to the pontiff the success of his mission. In order to quiet the possessors of church property, the legate issued his dispensation, declaring that they should not be molested; and a statute passed confirming his sentence. By another, the acts which had abolished the papal supremacy were repealed. This new restoration of power to the papacy formed a sad and dark augury for the devoted Protestants. It was the first indication that the time approached when the fires of persecution were to blaze forth in every county of England, and when heaven was to be insulted by the profanation of its sacred name as sanctioning the foulest deeds of blood.

An act was passed by the parliament of 1554 for the revival of the statutes of former sovereigns against heretics, and especially against Lollards; which revival was to take effect from the 20th of January 1555. During the last reign, no Roman Catholic had suffered capital punishment on account of his faith, nor does there appear to have been any kind of jurisdiction or mode of procedure for the trial of heresy, although the law remained in full force against anabaptists and anti-trinitarians, whose doctrines were looked upon both by Catholics and Protestants as sapping the very foundations of Christianity. It has been alleged by the opponents of Protestantism, that in *The Reformation of Laws*, composed in the latter part of Edward's reign, there are indications of a preparation for lighting the faggot against the adherents of the ancient religion; and as the point is of some importance, we shall avail ourselves of the following observations by Sir James Mackintosh, which seem to put the matter in its true light. Referring to the allegation that severity against the adherents to Catholicism was about to be put in execution, he says,

"This statement is chiefly grounded on a text of that projected code, which directs that contumacious and incorrigible heretics, after all other means have been exhausted, shall be at length delivered to the civil magistrate to be punished. It is assumed that the punishment must be death. Yet in the very first article of the code, which relates to atheists and unbelievers in Christianity, death is denounced against them in express words.

"The admission of it into another article by mere implication is therefore unreasonable. It is too terrible an enactment to be admitted without express words. If punishment is held to be synonymous with capital punishment, by force of this clause death must be applied to all heresies. If it was intended to confer on the civil magistrate a large discretion in the infliction of inferior punishments for the enumerated heresies, the article is perfectly agreeable to the practice of the framers and the opinions of the times. It is incredible that capital punishment could be denounced against the whole of a long series of heresies, of which the catalogue nearly occupies twenty quarto pages, besides what is called a monstrous heap of other errors, less necessary to be specified, as being less prevalent in that age. Even admitting this unreasonable construction of the plan for a reformed code, it affects only the reputation of the projectors. It never was adopted by public authority. It was not laid before parliament. There is no reason to doubt that the Protestant parliament would have altered the very articles in question, if, when they were communicated to that assembly, they could be supposed to establish or countenance a practice perfectly at variance with that of the king and parliament of England in the reign of Edward VI. To hold that a few words in a Latin manuscript, of projected but not adopted laws, not printed till many years afterwards, could have been the incentive of those who kindled the fires of Smithfield under Mary, is one of the most untenable of all positions. Truth and justice require it to be positively pronounced, that Gardiner and Bonner cannot plead the example of Cranmer and Latimer for the bloody persecution which involved in its course the destruction of the Protestant prelates. The anti-trinitarian and the anabaptist, if they had regained power, might indeed have urged such a mitigation, but the Roman Catholic had not even the odious excuse of retaliation."

History. 1555.

The year 1555 opened with gloomy forebodings for the reformed clergy; and ere a month had expired, the lowering tempest burst upon them with unexampled fury.

On the 28th of January a commission, with Gardiner at its head as lord chancellor, assembled in the church of St Mary Overies, in Southwark, for the trial of Protestants. From the station which this individual held, and from his commanding talents, there appears to be little doubt that he was instrumental in pushing forward this bloody work, although some writers have attempted to remove this reproach from his character. Whether he was the main author or not, is a matter of comparatively little importance. As lord chancellor, and as head of the commission, he sanctioned the whole proceedings. He must therefore be held responsible for the deeds of those who acted under his authority, and suffer the lash of posterity, in the same way as Cromwell, on whom Catholic writers have poured out the vials of their wrath, from his having acted as captain of the banditti who plundered the holy places in the reign of the eighth Henry.

The first martyrs in this persecution were Hooper bishop of Gloucester, and Rogers, a clergyman of Essex, both eminent divines of the reformed cause. They died with feelings of triumphant piety in the midst of suffocating flames; and other victims were rapidly hurried to the stake. The principal were, Archbishop Cranmer, Ridley bishop of London, and Latimer bishop of Worcester. (See CRANMER.) These persecutions soon became odious to the whole nation, and the perpetrators of them were all willing to shift the blame from themselves upon others. Many of the Catholic prelates, to their honour, exercised occasionally an effectual and perhaps hazardous humanity in their favour. Gardiner himself withdrew from this unavailing slaughter, and his place was supplied by Bonner bishop of London, a less scrupulous dealer in blood. Even Philip himself was moved to pity, and discountenanced these diabolical proceedings. To describe the sufferings of those persons of eminence and distinction who perished, would fatigue the patience and harrow the feelings of the reader. For four years the persecution was carried on with unsatiated cruelty; and, keeping out of view those who perished in dungeons under every form of misery, and also those who expatriated themselves, nearly three hundred individuals are calculated to have expired at the stake. We are positively informed by Lord Burghley, that in this number of victims are comprised no less than one hundred women and children. The perpetrators of these "more than heathen cruelties" deserve no quarter from posterity; such deeds as those laid to their charge stamp infamy deep on their names, and hold them up to execration now and for ever.

The other events of this reign unconnected with religion are, with the exception of the loss of Calais, unimportant. The reduction of this town had cost Edward III. a siege of eleven months, and the English standard had waved over its battlements for above two centuries. It surrendered to the arms of France after a siege of only eight days, and its loss so affected the queen, that when lying on her deathbed she said, "If you open me you will find Calais written on my heart." Philip, her husband, appears to have treated her with formal but cold respect.

History. 1558. He had succeeded to the greatest monarchy then in the world, and had been some time absent from England in superintending its affairs. He returned again, but his departure a second time left Mary to brood over her fruitless barbarity alone. She had more than once entertained the nation with rumours of her pregnancy, and was herself cheated with the illusive hopes of offspring. But this Shiloh of the ancient faith, like that of a celebrated dreamer of after times, was the manifestation of a deadly disorder. She died of dropsy on the 17th of November 1558, to the unspeakable relief of the greater portion of her subjects.

History has loaded the memory of Mary with merited opprobrium. Some Roman Catholic writers have endeavoured to palliate her conduct on the plea that she acted under the influence of religious principle, and from a conscientious desire to suppress opinions which she considered very dangerous to her subjects, and not from a cruel and bloodthirsty disposition; but, in mitigating her atrocities upon this ground, what a fearful charge do they bring against the system of religion which could so deaden the feelings of humanity and mercy in the heart of a woman, and could incite to such deeds of cruelty as earned for her among the common people the title of the "Bloody Mary," and which, even in the most accurate and sober narrative, excite just detestation.

There was nothing attractive in the private life of Mary, for her nature was sour and unamiable, and almost destitute of that tenderness which peculiarly distinguishes the female character. Whether or not she was a tyrant like her father, she was at all events pre-eminently fitted for becoming the tool of tyrants. It has been said that she was not altogether remorseless, for she is reported to have suffered some compunction on account of her conduct towards the Protestants.

After the death of Mary, the Princess Elizabeth succeeded to the throne without opposition. She was at Hatfield when the news of her sister's death were brought to her, and hastening to London immediately, she was received there with great joy. For the preservation of her life this princess was indebted to Philip, the husband of Mary. The Spaniard was aware that her death would remove the only obstacle which stood between Mary of Scotland and the throne of England. That sovereign had been married to the heir-apparent of France, his great political enemy; and the balance of power which might thus be thrown into the hands of the latter would have endangered the stability of Philip's throne; a circumstance which induced him to this unusual act of liberal humanity. The first measure of Elizabeth was to assemble around her throne a body of counsellors who had recommended themselves to public notice by the power of their talents or the steadiness of their principles. Her state council was composed of both Catholics and Protestants, although her more confidential advisers were confined to a select portion of the latter, and amongst these was Sir William Cecil, whom she appointed her first secretary. Precautionary measures were taken to meet any invasion on the part of France in order to raise Mary Queen of Scots to the throne; for the government of that country had made demonstrations to this effect, by instigating Rome to hostilities against Elizabeth. Mary had left a vacant treasury, and one of the first cares of the new administration was to obtain pecuniary supplies; and, from the high character and popularity of the queen, these were immediately granted by the people. Her coronation was then celebrated with all possible splendour and festivity.

To establish the Protestant religion was Elizabeth's most ardent desire. With this view the statutes passed in the late reign for the support of the ancient faith were repealed; and the acts of Henry VIII. in derogation of the papal authority, and of his successor in favour of the reformed church, were for the most part revived. There were some deviations in the new book of common prayer from the liturgy of Edward VI., but of these only two are important. The first consists in the omission of a prayer to be freed from the "tyranny of the bishop of Rome and all his detestable enormities;" which certainly displayed a conciliatory spirit towards the Catholic church. The second was an alteration of the language which spoke of the sacrament as being only a remembrance of the death of Christ, and the substitution of words which indicate the real but not corporeal presence. Towards the middle of 1559 the Protestant liturgy was introduced, and the oath of supremacy administered. Strong opposition to it was evinced on the part of the clergy, especially amongst those of a dignified station; and out of sixteen bishops only one took the oath tendered to them. But the lower orders were less scrupulous; and it is probable that in many instances necessity induced them to make a compromise with their consciences. Those of the clergy who refused compliance with the new code of religious doctrines were deposed, and their places supplied by professors of the reformed religion. According to the standard of punishments which followed contumacy in these ages, the treatment of the bishops was mild. Bonner was imprisoned; but he was a man so empurpled with blood as to be odious to all parties. This was the highest degree of suffering to which any of the nonconformists were subjected.

History. 1569. During the time that the queen and her counsellors were thus settling the religious affairs of the nation, negotiations were carried on between England and France for a peace, which was at last concluded on the following terms, viz. that the French king should restore Calais at the expiration of eight years; that in case of failure, he should pay five hundred thousand crowns, and Elizabeth's title to Calais should still remain; that for the payment of this sum he should find the security of eight foreign merchants, not natives of France; and that until such security was provided he should deliver five hostages. If during this interval Elizabeth should break the peace with France or Scotland, she was to forfeit all title to Calais; but if the French king was to make war on Elizabeth, he was to be obliged to restore the fortress immediately.

The reign of Elizabeth for the first eleven years, that is, from the twenty-fifth to the six and thirtieth year of her life, was distinguished for the internal quiet and happiness of the country. During this interval she displayed the very best qualities of a sovereign; firmness, prudence, vigilance, activity, and foresight. These qualities were tempered with habitual amenity, and a rational piety. By her subjects she was admired, applauded, and imitated; and during this halcyon period her throne received an accession of strength which enabled it to stand unshaken amid the tumultuous storms with which it was afterwards assailed. She was repeatedly advised to engage in a matrimonial alliance, but uniformly declined to do so, declaring her resolution of remaining single for life. Amongst her suitors were various foreign princes, Catholic as well as Protestant; and some of her own subjects even presumed to intrude their offers upon her "maiden meditation," but without success. During the religious war which raged in France, Elizabeth, ever ardent in the cause of the reformation, assisted the Huguenots with arms and money

In the mean time the pretensions of Mary, queen of Scotland, to the crown of England, involved Elizabeth in transactions which have left a stain upon her name. Mary, who was espoused to the dauphin of France, had quartered

History. 1569. the arms of England with those of France and Scotland upon her escutcheon; and to this she was advised by the Catholics, who looked upon Elizabeth as a usurper, having been illegitimised in her youth by the cruel mandate of her father at the time when he consigned her mother to the block. The result of this appropriation of the armorial bearings of the English sovereign was a quarrel between the two princes, which only terminated with the execution of the unfortunate queen of Scotland. See the article SCOTLAND.

In 1569 Elizabeth was excommunicated by Pope Pius V. These anathemas, by absolving subjects from the oath and the duty of allegiance, and suspending the offices of religion, and even those of humanity, were sometimes most disastrous to a country, upon which they descended like a deadly epidemic. But the majority of the queen's subjects were of the same religion with herself, and had thrown off the papal yoke; so that it was in the present instance productive of no other effect than the publication of a severe act against all who held any communication with the bishop of Rome. Severe measures were also taken with the puritans and other dissenters. At this time the English nation was divided into three theological and political parties; the *Churchmen*, who considered the ecclesiastical revolution as already perfect; the *Puritans*, who sought further reformation by agitating the minds of the people; and the *Catholics*, who, supported by the great continental powers, did not yet despair of seating their religion upon the throne. But men of all these persuasions united in their abhorrence of anabaptists; and, in order to extirpate them, the fires of Smithfield were, after an interval of seventeen years, re-kindled. Fox the celebrated martyrologist dared to interfere in behalf of this hated sect; but his courageous humanity obtained for them only a temporary respite. Two men were burned, and numbers were imprisoned or otherwise corporally punished. These events took place about the middle of the year 1575, and this was the first blood spilt by Elizabeth on account of religion; it, however, forms a dark stain upon her government, which may be pronounced mild when compared with others of the same period. The blood of Henry VIII. was not yet sufficiently purified in this its first descent from the fountain-head.

Amongst the other domestic events connected with the history of England, was that of the rebellion of Percy earl of Northumberland, and Neville earl of Westmoreland. This revolt partook both of a civil and of a religious character, for the noblemen at its head were adherents of the ancient faith, and were encouraged to embark in their lawless enterprise by the Catholic states. But on the approach of the royal troops under Sussex, the insurgents broke up and fled. Northumberland was made prisoner in Scotland, and executed at York; and Westmoreland died in Flanders, in the humble capacity of commandant of a Spanish regiment. Other treasonable transactions originated with the Duke of Norfolk, whose vaulting ambition aspired to the hand of Mary queen of Scots. Indeed he and the two insurgents just named, together with several other nobles, united in a conspiracy against Elizabeth. The timely arrest of Norfolk, however, disconcerted the confederacy, of which the northern rising was merely a premature explosion. Mary of Scotland is positively asserted to have been a participator in the plot. Norfolk was brought to trial; and there seems little doubt that he had incurred the penalties of treason, by having had intercourse with Catholic princes who had undertaken to land in England with a hostile army, and by his clandestine renewal of negotiations for the delivery and espousal of Mary, at that time a prisoner in the hands of Elizabeth. He was condemned to death, and executed, after a great deal of hesitation on the part of the queen.

History. 1588. England now began to distinguish herself in her natural career of maritime enterprise. Amongst the most distinguished of the nautical adventurers of this age was Sir Francis Drake, whose exploits will be found related under the article DRAKE. A vague rumour had for some time pervaded Europe, of vast naval preparations by the king of Spain, for the invasion and conquest of England. In 1587 Sir Francis Drake having been dispatched with a fleet to attack the Spanish ships which lay in the bay of Cadiz, was completely successful in his enterprise, burning and destroying above one hundred vessels laden with ammunition and naval stores. The fruits of his expedition were of vast importance. Philip's preparations were disturbed, and his project of invasion put off for twelve months, during which period Elizabeth had time to make head against the storm which was gathering in that quarter. These were the obvious results of Drake's bravery; but who can estimate the moral effect which it had produced? It gave a heroic impulse to the nation, and inspired it with confidence in its own strength and resources. It taught English seamen to look without terror upon the towering bulk of the Spanish vessels; whilst the Spaniards themselves must have in a proportional degree lost the confidence of having an advantage over the enemy by means of their floating castles.

The king of Spain having once more completed his complement of vessels, manned them with the ablest seamen and soldiers, under the command of the most renowned leaders. This Armada was truly imposing and magnificent; it was baptized The Invincible, but not with English blood. Never before had the ocean borne a more splendid fleet than that which sailed from the Tagus on the 25th of May 1588. The ships and their equipments had been fitted out in every port of its king's dominions. In Flanders, the forest of Waes had been felled; the dockyards of Antwerp, Dunkirk, Newport, and Gravelines swarmed with artificers; and the rivers and canals were covered with boats adapted for the transport of soldiers destined to serve in the expedition. On the 20th of May the following enumeration of the vessels was made: "The general sum was 130 ships, of 57,868 tons; 19,295 soldiers and 8450 mariners, with 2088 slaves, and 2630 great pieces of cannon of all sorts; also twenty caravals for the service of the others, with ten salvers of six oars a piece." Towards the end of June another armament of eighty sail left Lisbon to join them.[1] To meet this overwhelming armament the royal navy of England mustered 181 ships, containing between seventeen and eighteen thousand seamen. There were only eight ships above five hundred tons burden, and the largest was only eleven hundred. The aggregate burden of the whole English fleet amounted to 31,985 tons, being little more than one half of that of the Spaniards. The preparations made on land displayed equal spirit and enthusiasm. A loyal patriotism and active magnanimity pervaded the whole kingdom. The city of London set a noble example. The lord-mayor, in the name of the metropolis, put at the disposal of his sovereign ten thousand soldiers and thirty vessels. The whole nation emulated this wise liberality; and every city, town, and hamlet poured forth its ardent patriots to take their stand upon the coast and repel the insulting invader. About fifty thousand men under the command of Earl Hunsdon, a brave and able general,

[1] Strype, p. 538–9, from the Spanish book, which rather styled the whole "Felicissima Armada."

History. 1588. guarded the queen's person. The Thames at Tilbury was watched by Leicester with a considerable force. Sir Walter Raleigh was stationed at Portland Castle, in Dorsetshire, and the Earl of Sussex at Portsmouth. In the other parts of the country the wisest measures of defensive warfare were adopted. At sea one division of the fleet under Lord Henry Seymour guarded the narrow seas; whilst the main body under Lord Charles Howard, the high admiral, was stationed in the Western Ocean. The gallant Sir Francis Drake and the able navigators Hawkins and Frobisher were in this division.

Under the Duke of Medina Sidonia, the Spanish Armada set sail for the invasion of England. It was for some time retarded by a tempest, which also harassed the English fleet; and news were brought to the queen of England that Medina's Armada had been so injured and scattered that the expedition was for the present abandoned. The English ships withdrew to various ports, where they might have been surprised and burned, had not intelligence accidentally arrived that the Spanish fleet was bearing down full sail upon the coast. On the 20th of July the English admirals came in sight of the enemy, and next day the first engagement took place. The plan of Lord Howard was to evade a direct attack; for his vessels being so much inferior in bulk and weight of metal to the enemy's ships, were incapable of grappling in close action with them; but being superior in mobility and expedition, he resolved to annoy their rear, and to cut off the sluggish sailers. In the first attack neither fleet suffered much. Early in the morning of the 23d the second conflict began, and both fleets fought with valour; but the advantage was at last on the side of the English, over whose smaller vessels the iron shower from the higher sides of the Spanish ships flew harmless, whilst their own took full effect. On the 24th a pause took place in the battle, which was, however, renewed next day; but the mighty armament forced its way unbroken to the vicinity of Calais. They were now prepared to act in concert with the Duke of Parma, who had completed his preparations. He possessed in the harbours of Newport and Dunkirk transports which carried about twenty-eight thousand men, and which waited the general's command to make the grand attempt.

The concentration of the Spanish Armada off Calais suggested to the English admiral the idea of employing fireships to destroy it. Eight vessels were thereupon hastily prepared for this purpose, and during the night of the 29th, which was cloudy and boisterous, they were sent down blazing with combustible materials into the heart of the Spanish fleet. A cry of horror burst from the Spaniards, and, seized with an irresistible panic, they cut their cables with the intention of standing out to sea. But in their terror and confusion they inflicted severe injury upon one another; and, to augment their distress, a fierce gale sprung up, which scattered the Armada along the coast from Ostend to Calais. Some struck on the shallows at Flanders, whilst others beat out to sea; the remainder, amounting to about forty sail, were assailed by Drake and the rest of the English fleet. This was the most severe engagement which had yet taken place, and was maintained with great bravery for a whole day. The Spaniards lost several of their best ships; and after vainly endeavouring to regain their position in the narrow strait, where Parma could alone join them, they resolved to return to Spain by making a circuit round Great Britain. The want of ammunition compelled the English to refrain from pursuing the invaders at a time when they might have annihilated them. But this was reserved for an enemy even more formidable than that before which they fled. A storm overtook them on their unfortunate voyage, and the coasts of Scotland and Ireland were strewed with the wrecks of the Invincible Armada, so that only a feeble remnant of that splendid fleet reached the shore from whence it had sailed, in all the pomp and circumstance of war, as if to an assured triumph.

History. 1596. The events of Elizabeth's reign which followed the discomfiture of the Spanish attempt to invade England may be briefly related. The Earl of Leicester, who had for a long time maintained an enviable place in the queen's favour, was invested with fresh honours. A new and unprecedented office was created for him, that of lord lieutenant of England and Ireland, which exalted him to an authority only a little lower than that of sovereignty. But the ink was scarcely dry upon the warrant which wanted but the royal signature to complete the triumph of the favourite, when he was cut off by a violent disease, which, whether it arose from natural causes, or from poison being administered, at all events speedily terminated his career. Of this nobleman little need be said. He is one of a numerous class of historical characters who possess a degree of notoriety, not on account of any brilliant endowments which they themselves possessed, but from their proximity to or connection with distinguished personages. He possessed no intellectual or moral qualities which, deprived of adventitious aid, would have thrown him into the foreground of his country's history; whilst, if we listen to the opinion of his contemporaries, he must be looked upon as dissolute and unprincipled, notwithstanding his affectation of piety. He is a satellite only conspicuous from the light which is reflected upon him by his sovereign.

The English navy, emboldened by its late triumph, now made several very successful descents upon the Spanish coast, not so much for the purpose of obtaining permanent conquest, as of harassing the enemy. These expeditions were conducted by the most able commanders, amongst whom were some of the brightest names in the history of maritime discovery and enterprise, such as those of Raleigh, Drake, Cavendish, Hawkins, and Howard. It was then that the English navy assumed the empire of the sea, which it has ever since maintained with triumphant heroism.

On the death of Leicester, the young Earl of Essex succeeded him as prime favourite of the queen. But the desire of glory or the hope of plunder induced this volatile young nobleman to join the armament preparing to sail for Spain. The expedition was unfortunate, and when Essex returned to England, he found two rival candidates for royal favour, Sir Walter Raleigh and Sir Charles Blount. By the superior influence of these noblemen, the former was driven to cultivate a portion of land which had been granted to him in Ireland; and with the latter Essex fought a duel, in which he was wounded. But by the queen's command they were reconciled to each other, and in process of time they became sincere and attached friends.

In the year 1596, a new expedition was fitted out for Spain, which was completely successful. The Spanish fleet was defeated, and lost thirteen men-of-war. Cadiz was taken, and its defences, which rendered the town the strongest fortress in the country, were razed to the ground. This was the severest blow which the king of Spain received from his daring enemy subsequent to the repulse of the Armada. Matters might have been still worse with him had not dissension sprung up amongst the English commanders, the majority of whom, against the suggestion of Essex, who was one of the leaders, declared for an immediate return to England. The town, with the exception of the churches, was reduced to ashes; and the troops, taking with them the most valuable portion of the plunder, re-embarked, and the fleet returned to Plymouth in less than ten weeks after it had set sail. Essex, on his arri-

Statistics. 1603.

val in England, was compelled to appear before the queen in council, and answer to several charges connected with the late enterprise. These charges merely related to pecuniary matters, and the favourite was acquitted; but this was the commencement of numerous subsequent quarrels which he had with his sovereign, none of which are important to history except the last. Having been appointed lord deputy of Ireland, he suddenly left his command in that country and returned to England. He was committed a prisoner, and called upon to account for his extraordinary conduct. The queen, however, was unwilling to carry matters too far against her favourite. He was allowed to go about as a prisoner on parole; but this high-spirited and aspiring nobleman could not remain content with the humiliating circumstances to which he was now reduced. He attempted to excite the city of London to revolt against the queen's authority; but the rebel was taken prisoner, tried for high treason, condemned, and executed. This proved a severe blow to Elizabeth, who was now tottering upon the brink of the grave. She had been all her life subject to fits of indisposition, which were occasionally violent; but it was not till the beginning of March 1603 that her mortal illness came on. Her mind became depressed with gloomy recollections, especially those connected with the shedding of Essex's blood; and her nervous melancholy and general decline increased, accompanied by symptoms which indicated a disease of the heart, and by a laboured and convulsive respiration. She was questioned by her confidential advisers as to her successor, and signified her desire that the king of Scotland should succeed to the throne. Her speech soon afterwards failed entirely, and all hope of her recovery vanished. She tranquilly breathed her last, about three hours after midnight, on the 24th of March 1603, in the sixty-seventh year of her age and the forty-fifth of her reign.

In the opinion of her contemporaries, whose judgment has been ratified by posterity, Elizabeth ranks amongst the greatest and the most fortunate of English sovereigns. The domestic tranquillity which signalized her rule during nearly half a century; her triumphant repulse of the Spanish monarch, and the severe retaliation which she inflicted upon that lord of empires; the spirit displayed by her navy in its numerous warlike expeditions by sea, and also by her army on land, are indications of uncommon vigour on the part of the sovereign, and of sagacity on that of her counsellors. She found England comparatively inferior to other nations of Europe, but she left it amongst the proudest and the most powerful. It was during her reign and that of her successor, that the human intellect sprung up at once to full maturity, and produced those works which are the peculiar glory of English literature. Hers was the Augustan age of poetry, the age of Spenser, Shakspeare, and others; and during her reign Bacon began to put forth those gigantic energies of mind which were destined to change the whole aspect of science, and even the condition of man as a civilized being. The human failings ascribed to Elizabeth are, excessive vanity, love of popularity which is part of it, parsimony, and a leaning towards despotism. But those whose interest it has been to vaunt the glory of her sister's reign, and the purity of her life, have not failed to charge Elizabeth with great personal depravity; yet if we discredit every defamatory story which can be clearly traced to her enemies, the imputations will not have much weight, or attach any grave stigma to her name.[1] She is not, however, free from the stain of blood, the shedding of which cannot be justified, however it may be palliated by taking into account the circumstances of the times, and the critical situation in which she stood; but in this respect her conduct is almost purity itself compared either with that of her sister or of her father. For an account of the private life and literary character of this great queen, see the article ELIZABETH; and Turner's *Elizabeth*, vol. iv., p. 564.

She was succeeded by James the Sixth of Scotland and First of England. From that period, the history of the countries is given under the article BRITAIN. (J. F. S.)

PART II.

STATISTICS.

I.—*Situation, Extent, Face of the Country, Soil and Climate.*

Situation and extent. England, the southern, and by far the most fertile division of Britain, corresponds in latitude with Holland and the north of Germany, extending from 50. to 55. 45. N. Its figure is nearly triangular, and its extent of coast is very great, both from being much indented, and from the sea bounding it on all sides except along a width of 70 miles on the Scottish border. The adjacent seas are the German Ocean on the east, St George's Channel on the west, and the English Channel on the south. No country can be more fortunately situated; its climate is temperate; its extent is sufficient for its political security; whilst its insular position not only presents the greatest capabilities of aggrandisement in a commercial sense, but has, by rendering a great military force unnecessary, in all probability been the chief cause of preventing the executive branch from usurping absolute power, as in the countries of the Continent.

Its superficial extent had long been a question of considerable doubt, and the different estimates varied no less than 10,000,000 of acres. Mr Pitt, on the authority of Arthur Young, assumed, in 1798, the superficial extent of England and Wales to be nearly 47,000,000 of acres; a later calculation by Dr Beeke, approaching more to accuracy than any preceding one, fixed it at 38,500,000 acres. But, according to the census of 1851, the area of the great territorial subdivisions of Great Britain is as follows, viz.: England, 50,922 sq. miles; Scotland, 31,324; Wales, 7398; and the Islands in the British Seas 394 sq. miles; making the area of England and Wales 58,320 sq. miles, or 37,324,915 imperial acres. The forms of the islands are irregular, and do not approach simple geometrical figures, if we except England, which was not inaptly compared by the ancients to a triangle. The area of Great Britain is equal to a square of 299 miles to the side; England to a square of 226 miles to the side; Scotland to a square of 177 miles to the side; Wales to a square of 86 miles to the side; the Islands in the British Seas to a square of 20 miles to the side. While the area is in the ratio of these squares, or as 51, 31, 7, and $\frac{4}{10}$, the population is nearly as 17, 3, 1, and $\frac{1}{7}$; England has, on an average, to a square mile 332 persons, Wales 136, Scotland only 92, the Islands in the British Seas 363 persons. While about 21,200,000 acres of territory lie north, and 36,400,000 acres south of the 55° of north latitude; the populations on the north and south side of the line are respectively about 3,173,000 and 17,787,000.

Face of the country. England is generally a level region, though it is traversed in different directions by ridges of considerable elevation, forming the watersheds of the country. The northern part

Statistics. of the kingdom (including Westmoreland, with portions of Cumberland, Lancashire, and Yorkshire) is mountainous; and a chain of hills, varying in elevation from about 1200 to 3000 feet, extends southward from the borders of Scotland to the middle of Derbyshire. A range of table-land (rising sometimes into hills, and attaining a height of 1500 feet) extends in a tortuous line through the East Riding of Yorkshire, and the counties of Lincoln, Northampton, Oxford, Gloucester, Somerset, and Dorset, where it terminates with the isle of Purbeck. It is chiefly composed of oolitic rocks, rising above the lias formation, and presents generally a bold escarpment to the west, with a regular slope to the east. The southern and eastern counties are traversed by ranges of chalk hills of small elevation, diverging from Salisbury Plain. One of these extends eastward through Hampshire and Sussex to Beachy Head, forming what are called the South Downs; a second extends through Hampshire, Surrey, and Kent, forming the North Downs; and a third passes north-easterly through the counties of Berks, Oxford, Bucks, Bedford, Cambridge, Suffolk, and Norfolk, where it forms the eastern border of the fens. Devon and Cornwall are occupied by mountains of granitic formation, and Wales by a series of high and rugged mountains, forming several groups and chains between the vale of the Severn and the Irish Sea. It would therefore appear that the highest and most rugged part of England is to be found near its western coast, while the principal plains and lowlands lie towards the German Ocean.

Geology. To the south-eastward of a line drawn from the isle of Portland, by Oxford, Northampton, Leicester, Nottingham, Doncaster, and York, to the vicinity of Scarborough, the whole of this district is composed of chalk, calcareous sandstone, and other secondary strata, or alluvial ground, in which there are no beds of workable coal or metallic veins. To the westward of the above line the country is composed of secondary strata of a different description, in many parts of which beds of coal and ironstone are found. To the north and west of this second district are found mountains of metalliferous limestone. Granite and granitic rocks are found in Cornwall, Devon, North Wales, Anglesea, the Malvern hills in Worcestershire, Charnwood forest in Leicestershire, and in Cumberland and Westmoreland. Primary stratified rocks are chiefly limited to the clay-slate, grauwacké, and silurian systems; the first two of which extend over the south of Cornwall and Devon, the northern part of Devon, a large portion of Wales, and nearly the whole of the lake districts of Westmoreland, Cumberland, and Lancashire. Gneiss and mica-slate are almost unknown, though traces of them are to be found in the Saddleback rocks in Cumberland, and in the Isle of Man. The secondary rocks commence with the carboniferous system, which is extensively developed in the northern counties and in South Wales, and the adjacent parts of England. Outlying groups of this system occur likewise in other places. Millstone-grit rocks, which prevail to a great extent in the north of England, are, however, little known in the southern carboniferous region; while, on the contrary, the old red sandstone, which is enormously developed in the latter, is limited in the north to a few inconsiderable traces. The saliferous or new red sandstone system commences at the Tyne, and skirts the northern carboniferous region to near Liverpool. It is found also near Carlisle, in the upper part of the estuary of the Severn, and in the valley of the Exe. The oolitic system, as already mentioned, forms a belt nearly 30 miles in breadth, extending from Yorkshire to Dorsetshire —supplying some of the best building materials in the kingdom. A fresh-water formation, called the Wealden, extends over a large portion of Kent and Sussex. The cretaceous system, or chalk formation, extends from Flamborough Head in Yorkshire (though interrupted by the Wash) to Sidmouth in Devonshire, forming the ranges already referred to. The tertiary strata consist chiefly of the argillaceous formations, abounding in organic remains, named the plastic clay and the London clay; extending over Middlesex, Essex, Suffolk, and portions of Kent, Surrey, and Norfolk. A variety of the same formation is found on the south coast, from Brighton on the east to Dorchester on the west. The localities of the post-tertiary or diluvial and alluvial formations are too numerous to admit of specification in such a sketch as the present.

Trap has found its way through all the stratified formations, but occurs in masses of varying dimensions in different places.

The coal-beds of England, contained in the carboniferous system, are found in Northumberland and Durham, south Yorkshire, Nottingham and Derby, south Lancashire, Staffordshire, Warwickshire, Anglesea, Flint, Salop, Worcestershire, Gloucestershire, and the northern part of Somerset, South Wales, and near Whitehaven in Cumberland. Iron is found in inexhaustible quantities in all the formations. Lead is found chiefly in the mountain limestone, copper in the granite and older primary stratified rocks, tin in Cornwall and Devon. Salt springs, yielding large quantities of salt, are found in Cheshire and Worcestershire.

Sea-coast. The sea-coast of England presents a very different aspect in different situations; in some quarters—as in Cornwall, Kent, part of Norfolk, and Wales—it is steep and elevated; in other parts it is low, sandy, or marshy; exhibiting, on the whole, a variety which hardly admits of being brought under a uniform description, and which, though partaking much more of a level than rugged character, still differs greatly from the opposite shore of Flanders, Holland, and Friesland, which is one continued flat for more than 300 miles.

Rivers. Of the rivers of England, the largest are the Thames, the Severn, and the Trent. The Thames has no pretensions to romantic effect in any part of its course, nor is its body of fresh water large; but it is navigable for more than 120 miles, and, in the approach to London from the Nore, presents to the admiring spectator a prospect which, whether we consider the quantity of shipping, the thickening population, or the high state of improvement of its banks, is wholly without parallel. The Severn, though not equal to the Tay in quantity of fresh water, is superior to the Thames, and during the first part of its course preserves the characteristics of a mountain stream, being clear, and at times bordered by picturesque scenery; but, on leaving Wales, and entering a more level country, it assumes a different aspect, and becomes a full slow-flowing river, admitting of easy navigation, and facilitating greatly the commerce of Shropshire, Worcestershire, and Gloucestershire. Towards its mouth it receives the Wye, a large navigable river from Wales. The Trent rises in Staffordshire, and—after a course often tortuous, but generally in a north-east direction—falls into the Humber, which soon after becomes a broad estuary. The Mersey, as a river, is of no great importance; but as an arm of the sea it affords from the west a very capacious inlet to the trade of Liverpool, and facilitates the conveyance of the produce of the interior. The Tyne is a large stream, having Newcastle on its banks, and Shields near its mouth. The Medway, as a fresh-water river, is small and sluggish, but acquires, by the influx of the tide, such a depth of water at Chatham as to adapt it to the reception of the largest men-of-war. It is only the rivers of Wales, Westmoreland, Cumberland, and a few mountainous districts, that are rapid or transparent; the great majority of English rivers, particularly in the eastern and central part of the kingdom, are slow in their course, and owe the degree of beauty which they possess less to the effect of the water or scenery than to the high cultivation and elegant disposition of the adjacent grounds.

Lakes and forests. A similar remark applies to the lakes of England. Nothing can exceed the beauty of Windermere, Keswick, and Ulleswater; whilst the unvaried and uninteresting collections of water, such as Whittleseameer and others in the fen district, are to be compared only to those in North Holland

Statistics.

or Friesland. In regard to wood, England is very well provided, without having many of those extensive forests which are met with on the Continent upon great mountain ranges, such as on the Jura ridge between France and Switzerland, and the Suabian Alps upon the Upper Rhine. It is in private plantations of limited extent, but of frequent occurrence, and sometimes of great beauty, that the chief stock of English timber is to be found. Several very extensive tracts—such as the New Forest in Hampshire, the Forest of Dean in Gloucestershire, and Sherwood in Nottinghamshire, belong to the crown.

Soil and produce.

The soil of England is suited to a great variety of products; but it has not the exuberant fertility of southern climates, much labour and vigilance being requisite to obtain from it a grateful return. The quantity of moisture makes it admirably adapted for pasture; a characteristic which does not particularly strike those whose travels have never extended beyond their own country, but is of the highest importance in the view of those who have visited the Continent, and have witnessed the parched and arid state of the richest plains in the months of autumn. In regard to husbandry, it happens, by a singular coincidence, that in England, as in Scotland, the best is practised in the east part of the island, particularly in Norfolk, Lincolnshire, and Northumberland. As to mineral treasures, the eastern counties of England, to the south of Yorkshire, are remarkable for containing no mines, either of coal or of metal; these valuable deposits are found in the more uneven districts of the north and west, viz., in Northumberland, Durham, Westmoreland, Lancashire, Shropshire, Worcestershire, Somerset, Devon and Cornwall, in Wales, and in the midland counties of Warwick, Stafford, and Derby. In the east, particularly in Lincoln and Cambridgeshire, vast improvements have been made in the present age by draining; but there are still the means of making further and valuable acquisitions. Much also remains to be done in bringing into culture extensive heaths and moorlands in almost every county in the kingdom. The soil of these is in general poor, but the tillage required would seldom be obstructed, as in many parts of Scotland, by the ruggedness of the surface. Comparing the soil of England with that of the adjacent countries, we find it greatly superior to that of Scotland, except along our eastern coast; it is perhaps better also than that of Ireland, fertile as the latter naturally is; nor needs it, on the whole, dread a comparison even with the soil of France, where, amidst districts of great beauty and luxuriance, the eye of the traveller is often struck with extensive tracts of heath or marsh.

* The counties of which the eleven statistical divisions of England and Wales are composed are not strictly identical with the counties proper, but are aggregates of entire registration districts or poor-law unions, and are called, for the sake of distinction, "*Registration Counties.*"

Statistics.

The total amount of real property in England and Wales, as assessed in 1843, was £85,802,734; of which—lands, £40,167,088; houses, £35,556,400; tithes, £1,960,331; quarries, £207,009; mines, £1,803,794; iron-works, £412,022; fisheries, £10,967; canals, £1,229,196; railways, £2,417,610. The following table gives the amount of property assessed under the different schedules of the Property and Income Tax Act in England and Wales, for the years ending 5th April 1814 and 1815, and 1843 to 1851.

Years ending 5th April.	Schedule A. Lands, Houses, Mines, Quarries, &c., in respect of Property.	Schedule B. Lands, Houses, &c., in respect of Occupancy.	Schedule C. Dividends from the Public Stocks, &c.	Schedule D. Profits derived from Trades, &c.	Schedule E. Salaries and Emoluments of Persons in Public Offices.	Total Amount of Property Assessed.
	L.	L.	L.	L.	L.	L.

Climate.

The climate of England is that of an insular country of limited extent, subject in consequence to rain, and exempt from intensity of either heat or cold. Compared with the adjacent countries, it is less humid than Ireland, which, like Portugal, in a different latitude, is the first land to intercept the vapours of the Atlantic; but, on the other hand, the climate of England is less dry than the opposite shores of Holland and Germany, to which every wind but the west arrives across a tract of continent. The climate of the S. of England resembles much that of the opposite coast of Brittany, Normandy, and Flanders; whilst that of the N. is very similar to the temperature of Denmark, which, like the N. of England, is a narrow country inclosed on either side by the sea. In regard to the relative degrees of heat or cold, if England have not so much summer warmth as continental countries on the same parallel, she generally escapes in winter that intensity of frost, which in less than 48 hours of easterly wind so frequently seals up their harbours. On the other hand, our weather is much more variable than in the inland part of the Continent, and our sky is less clear; still it by no means follows that the balance of disadvantage is on our side. The moderate heat and frequent returns of rain preserve throughout the year that verdant pasture, which in autumn the Continent enjoys only in its maritime districts; whilst those droughts in spring, which are so noxious in the S. of France and in similar latitudes of the Continent, are hardly known among us. In point of salubrity, also, we may fairly stand a comparison with our neighbours; for, variable as is our atmosphere, no country perhaps exhibits a larger proportion of examples of longevity.

There exists, however, a considerable difference in the climate of different parts of England. The W., exposed to the Atlantic, and containing hills and mountains which intercept the clouds, is much more rainy than the E., where the aspect of the country is level, and the expanse of adjacent water much less considerable. Another and equally remarkable difference arises from latitude, the season being a fortnight or three weeks later in the N. than in the S. of England. Notwithstanding all the skill of the Northumbrian farmers, the traveller who leaves the harvest finished in the S. of England in the first week of September, and who sees the corn cut, if not carried, in the midland counties, will generally find it in the middle of that month untouched, and standing in most parts of the country to the northward of York. In winter this difference in the temperature of the N. and S. of England is less perceptible. As to the spring months, March is proverbially raw and cold, from the prevalence of easterly winds, particularly in that part of the kingdom adjacent to the German Ocean. April is in general wet and favourable to vegetation; but May, though a pleasant month, can hardly be said with us to bring more "indulgent skies." It is in June, July, and August, that our climate assumes a more settled aspect; whilst, at the same time, the power of taking exercise on almost any day is indicative of a very gratifying advantage over the sultry atmosphere of our southern neighbours on the Continent. November, though frequently wet and foggy, is only a prelude to winter; even December does not often bring intense frost, which is commonly reserved for January; and during the last 20 years we have been repeatedly without any frost of consequence, or heavy falls of snow, until a considerable time after the days had lengthened.

Variations of temperature.

During the six winter months, from October to March, the mean temperature of the central part of England is commonly between 42° and 43° of Fahr. In December, January, and February, it is generally below 40°; in July and August 62° to 65°. The variations of temperature within the space of 24 hours are felt most strongly in the equinoctial months, March and September. In these there is often a difference of 18° or 20° between the day and the night, whilst in the summer months this difference seldom exceeds 12° or 15°, and in December or January is only from 6° to 8°. The mean annual temperature, noon and night, of the central part of England, is about 50°. The greatest summer heat seldom exceeds 80°, and the cold of December or January is rarely below 20° or 25°. In mild situations in Devonshire and Cornwall, the winter temperature is 2°, 3°, 4°, and even 5° higher than in London. Penzance is the spot in England least visited by severe cold; and it is consequently much recommended in pulmonary cases.

Of rain, the largest proportion falls in the N.W. of England, particularly in Westmoreland and Lancashire, owing to the neighbourhood of the sea and the height of the mountains. There the average quantity is found to be 45, 50, and, in some situations, 60 inches, whilst the average of the kingdom at large is from 30 to 40 inches.

Prevailing winds.

The prevalent winds in England are W. and S.W. Our outward-bound merchantmen are often detained, from the want of a northerly or easterly wind; but it rarely happens that our homeward bound are kept beating in the channel by the want of a westerly breeze. In these respects, also, the case is the same on the opposite shores of the Continent; the Dutch and French outward-bound vessels often experiencing detention from the continuance of westerly winds.

Statistics.

II.—*Civil Divisions.*

Civil divisions.

The civil divisions of England are those of counties, hundreds, and parishes. The county divisions, like several of our national improvements, date from the reign of Alfred, and, though subsequently increased by the acquisition of the three northern counties from the Scotch, have not, in other respects, experienced much alteration since his time.

The 12 counties of Wales added to the 40 counties of England, make a total of 52. The name of "county corporate" is given to most of the cities of England, and to some of the towns; and this distinction, little attended to by the public, and seldom mentioned but in law papers, implies that the district in question is governed by its own sheriffs and other magistrates, to the exclusion of the officers of the county at large.

The counties of England and Wales have undergone considerable changes in the ancient territorial sub-divisions of the country.

The observance in Wales of peculiar laws and customs, combined with the use of another language by the people, naturally tended to maintain in a marked manner the distinction, which still exists in a less degree, between the inhabitants of the principality and those of England. Partly with a view to remove this distinction, an act was passed in the 27th year of Henry VIII. (A.D. 1535), declaring Wales to be for ever incorporated with the realm of England, and that all natives of Wales should enjoy the same liberty as the king's other subjects, with the like laws, justice, and customs of tenure. By this statute, all the marshes or border lands between England and Wales were either formed into new shires, or added to old ones. The new counties thus created were Monmouth, Brecon, Radnor, Montgomery, and Denbigh; Monmouth being named as an English county.

Few changes have been made in Scotland in respect of county limits; although the confused manner in which the component parts of some of the counties are scattered over the mainland and islands, and the frequent intermixture in others of detached parts of adjoining counties, must be productive of inconvenience.

Under the Reform Act, all the large and populous counties of England have been divided for the purpose of returning additional members to parliament.

Where portions of counties were detached from the main body of their respective counties, and locally situate in other counties, it was enacted that, for the purposes of elections, every such portion should be considered to be part of the county or division by which it was wholly surrounded, or, if bounded by more than one, of that county with which it had the longest common boundary. Some exceptions were, however, admitted; and the town of Dudley, with other portions of the county of Worcester, lying in contiguous counties, and certain portions of the county of Flint, were allowed to remain undisturbed.

A bill was subsequently passed, in 1844, under which every detached part of a county in England and Wales has become, since the 20th October 1844, *for all purposes* part of the county to which it had been annexed for parliamentary purposes.

About one-half of the English counties have thus been altered more or less. The only considerable changes, however, are those affecting the counties of Worcester and Salop, Durham and Northumberland. An addition of surface, amounting to 17,403 acres, with 20,401 inhabitants, has been acquired by Worcestershire, consisting chiefly of portions of the parish of Hales-owen lying in that county, but belonging to Salop, from which they have been severed. Northumberland has gained an additional area of 64,389 acres, containing 19,035 inhabitants, by the annexation of the districts of Islandshire and Norhamshire, and other parts of Durham which were locally situated either north of Northumberland or in the body of that county. The other counties which have increased are Oxford (by nearly 7000 acres), Sussex, Bucks, Devon, Hereford, and York.

Statistics.

Besides Durham and Salop, the English counties which have undergone some curtailment of territory are Hants, Berks, Hertford, Wilts, Dorset, Cornwall, Somerset, Gloucester, Stafford, and Monmouth.

Of the Welsh counties only four are altered, viz., Brecon, Radnor, Montgomery, and Denbigh; and these are affected to a very trifling extent.

Changes have also been made in the boundaries of many of the old corporate towns, while the limits of others equally requiring readjustment have been allowed to remain undisturbed. The obvious necessity, arising from the rapid growth of many of the boroughs, for an extension of their limits, in relation to the parliamentary franchise, was no less apparent with respect to municipal government; and it was deemed just and reasonable that all possessing a community of interest, as inhabitants of one town, should, while sharing many common advantages, also bear their due proportion of the burdens attaching to the corporate institutions. A general revision, and the extension where necessary of the boundaries of boroughs, was therefore deemed an essential part of the plan of reform, under the Municipal Corporation Bill. When that measure became law, the commissioners appointed to inquire into the municipal boundaries had accomplished only a small portion of their task. It was provided, therefore, as a temporary arrangement, that with respect to certain boroughs returning members to parliament, the *parliamentary* boundaries should be taken for municipal purposes until altered by parliament, and that, with respect to the remaining boroughs, their limits should remain unaltered, until parliament should otherwise direct.

In 1837 the commissioners made their report, and suggested, in numerous instances, new municipal boundaries for boroughs sending members to parliament, and for most of the unrepresented towns. The general effect of their recommendations was to extend the existing boundaries, so as to take in suburbs and localities immediately connected with the towns; in a few cases, rural parts included within the ancient limits were to be left out. Many of the proposed changes were, however, for various reasons, opposed by the inhabitants; and the municipal boundaries are suffered to remain in the state in which they were left by the act of 5th and 6th Will. IV., cap. 76. Of 178 boroughs in the schedule of that act, 60 were enlarged by the adoption of the parliamentary limits; but no extension of area has taken place in 118 boroughs—including the whole of those not possessing the parliamentary franchise—although no inconsiderable number of them has strikingly increased in population. As a consequence, it not unfrequently happens that the municipality scarcely represents the *town* any more than the *City* of London represents the metropolis of the British empire.[1]

By the enlargement of the 60 cities and boroughs referred to, contiguous parts, containing in 1851 a population of 510,852, have been brought within the pale of municipal institutions; the population within the old limits being 1,185,850, and within the present limits 1,696,702.

The Act for "the Amendment and Better Administration of the Laws relating to the Poor," empowered the Poor Law Commissioners "to declare so many parishes as they may think fit to be united for the administration of the Laws for the Relief of the Poor." The united parishes were designated *Unions.* The act also provided for the election of a representative board of guardians, and for the appointment of officers in every union, by whom the local rates for the relief of the poor, and for many other purposes, are collected and expended. The *Unions,* under the Act for Registering Births, Deaths, and Marriages in England, were subdivided into as many smaller districts as the Commissioners, subject to the approval of the Registrar-General, thought fit. The whole of England and Wales has not been placed under the Poor Law Amendment Act; but the Registration Act extends over all England and Wales, which is thus divided into 624 new districts. A district comprises on an average three or four *subdistricts,* to each of which there is a registrar of births and deaths. A subdistrict extends over a certain number of parishes or townships, except in those rare cases where the parish is large, and is itself made *one* or *more subdistricts.* The subdistricts contain on an average

[1] The borough of Stockton may be mentioned as an example. Its ancient limits, to which the present reformed municipal jurisdiction is confined, contained a population, in 1851, of only 1867; while the *town,* of which the borough forms but a fraction, contained 9808 inhabitants.

Statistics. seven parishes, townships, or places, of which the population is, in 16,008 cases, separately returned.

To the new districts a staff of officers is attached; and, where they are unions, there are the clerk to the Board of Guardians, relieving officers, medical officers, superintendent registrars, and registrars, whose duties are defined by the Poor Law Board and the Registrar-General. A system of rating is in operation; and the districts have practically been found useful for other administrative purposes besides those which were in contemplation at the time of their formation. Besides the subdivisions—ancient and modern—which have been described, others exist for a great variety of purposes: these are often of a complex character, and evidently made quite independently of each other, as the boundary lines cross in every direction. The late Mr Rickman noticed that "there are in England and Wales about *550 parishes* which are known to extend into *two counties*, or into more than one hundred, or other division;" and he pointed out "the scattered confusion of the component parts" of the ancient hundreds, as well as the irregularities in their size: "so irregular," he says, "is this distribution of territory, that while some of the southern hundreds do not exceed two square miles in area, nor one thousand persons in population, the hundreds of Lancashire average 300 square miles in area, and the population contained in one of them (Salford hundred) [in 1831] is 430,000."

The cause of these irregularities is evident. The division of England and Wales into hundreds, on the original plan, of which Kent and the counties in Wessex offer examples, was never carried out; and in the course of the thousand years that have since elapsed, the face of the country has undergone great changes: the distribution of the population—which from less than *four* millions has increased to *eighteen millions*—is no longer the same. A hundred no longer contains a hundred families. Bridges have brought into intimate union populations which rivers divided; villages have grown into vast cities; the mining and manufacturing industry of the last hundred years has covered the woodlands, wastes, and desolate lands of the midland and northern counties with people. The hundred courts, the manor courts, the shire motes, the burgh motes, have been superseded by the petty sessions, the county courts, the town councils, the boards of guardians; that discharge duties—such as the election of members of parliament, and the relief of the poor—never contemplated when the counties, boroughs, and hundreds were formed; while the system of *frank-pledge* in tythings has disappeared. For all the useful purposes of comparison and statistical inquiry, the old divisions in many parts of the kingdom are entirely unsuited. The legislature, then, without any settled plan, has in recent acts of parliament entirely disregarded the old divisions of the country into hundreds, and has changed in numerous instances the boundaries and divisions of counties as well as boroughs.

Counties.—The 40 counties of England, 12 of Wales, 32 of Scotland, making 84 counties in Great Britain, vary much in size and population. The English counties consist of a variable number of hundreds, and until latterly had detached parts within each other's limits.

The shire is an important subdivision of the kingdom, and each shire has numerous officers: (1) a lord-lieutenant, who is also (2) custos-rotulorum, or keeper of the archives, except in counties of cities; (3) a sheriff, who appoints (4) an under-sheriff; (5) justices of the peace, all appointed by the crown; (6) a county treasurer, and (7) a clerk of the peace, generally an attorney, who is appointed by the custos-rotulorum; (8) the county-coroners are elected by the freeholders, as (9) knights of the shires were formerly. The revenue of the shires is chiefly derived from rates which are struck by the justices of the peace in counties at quarter-sessions. The rates, which were formerly collected by the high constables, or constables of hundreds, are directed under 7th and 8th Vict. cap. 33, to be collected by the boards of guardians, and to be paid by them to the county treasurer. The county expenditure is chiefly incurred in maintaining bridges, gaols, police, prisoners, lunatic asylums, and the various county officers, some of whom are paid, although several of the offices are honorary, and are discharged gratuitously.

Hundreds.—Subdivisions of the shires have existed since the age of Alfred; and hundreds, tythings, and hides, are named in the early Saxon laws, charters, and other records. The notices are, however, by no means precise; nor are they all consistent, either with themselves, or with what is found to exist of the ancient divisions in later times. The simplest view may be thus stated: England was divided into hides—about 274,950 in number; and a hide of land, containing 100 or 120 acres, supported a free family: *ten* such free families constituted a *tything*; *ten* or *twelve tythings*, a *hundred*; an indefinite number of hundreds, a shire. The hundred is used in the Domesday return (1086) as a well-defined territorial division of the county.

The division of men into tens, twelves, hundreds, and thousands, on the basis of their system of numeration, is so natural, that instances occur of its use in the history of almost every nation; but it is not probable that Alfred, or any of his successors or predecessors, ever succeeded in organizing all the races, tribes, and states in England so simply as the above theory implies, without reference to other considerations than mere numbers. If the holdings were ever equal in extent, or the numbers of men in townships and hundreds the same, they could not continue unchanged: as the numbers and settlements of the people increased, and as the properties were so frequently won and lost by conquest, as well as the other mutations incidental to societies of men in the civilized as well as the barbarous state. Accordingly, it is found that the hundreds, in the survey after the Conquest, and the hundreds still remaining as constituent divisions of the country, differ to such an extent in area and population—not only in different, but in the same counties, and in similar situations—that it is difficult to conceive they could ever have been formed on a uniform scale of area, or of free population.

Sessional Divisions.—The divisions existing in all the counties of England and Wales for the purposes of special and petty sessions, are in general based on the *hundreds* and other ancient county subdivisions. By the authority of various acts of parliament the justices at quarter sessions may alter and rearrange these sessional divisions, and they are empowered to adopt the same limits as those of poor-law unions. The divisional meetings of the justices or petty sessions in 1831 amounted to 609 in England and Wales.

For the purposes of assize and gaol delivery, there are in England and Wales eight circuits of the judges, besides the jurisdiction of the central criminal court at London. The circuits are known as the Home, Midland, Norfolk, Oxford, Northern, Western, North Wales, and South Wales circuits, and include the counties situated in the parts of the country implied by their names.

Municipal Cities and Boroughs.—When the Anglo-Saxons first invaded England "the woods" were no longer "the towns" of the natives. The Britons had been collected in cities, polished but subjugated by the Roman legionaries, who lived in villas and towns, on taxes which their publicans collected. Unlike the adventurous colonists and "Pilgrim Fathers," who planted the British race in America, they did not find nations less civilized than themselves on the land, but more corrupted; less capable of freedom, and of political organization. As the Roman towns still existed, some of their forms and institutions may have remained; and have impressed on the populations of London, York, and other cities, some modification of the national institutions of the Anglo-Saxons and Scandinavians. Those modifications can, however, rarely be traced. The condition and circumstances were no longer the same in the fertile cultivated soil of England as they had been on the western shores of the continent, and the new races adapted themselves to the change; but their relations to each other, to their families, and to their princes, required free institutions of a character very different from the provincial organization of the declining Roman empire. The Saxon borough was a modification of the hundred; the burgesses were freemen bound to each other as neighbours, responsible for each other to surrounding communities, sharing common burthens; classified further in guilds of trades, or companies, which sprang up with the divisions of labour; and banded firmly together for the defence of their walls and dwellings.

The hundred necessarily underwent some modification in the towns; and in this as in other cases it soon ceased to designate a specific number of men. But it is of importance to observe, that in the early times the same principles of subdivision, organization, and government were applied alike to town and country populations.

Statistics.

London, Winchester, Abingdon, and some other boroughs of importance, are not entered in Domesday, and were probably not surveyed by the commissioners of William I., but the customs of 41 cities and burghs are noticed with some detail.

The eleven cities of London, Bristol, Canterbury, Chester, Exeter, Gloucester, Lichfield, Lincoln, Norwich, Worcester, York: and the five towns of Kingston-on-Hull, Newcastle-on-Tyne, Nottingham, Poole, Southampton, in England; and two, Caermarthen and Haverfordwest, in Wales, are "counties of themselves:" as was also the city of Coventry until lately. The cities on the old Roman sites maintained their independence of the country around them, as well as of the early Saxon kingdoms, to a larger extent than other towns; as is indicated by their independent county jurisdiction.

Some of the ancient boroughs fell into decay; new boroughs sprang up in other parts of the country; many towns were created boroughs for purposes not now very intelligible; and with the rapid progress of population which commenced after 1750, and has gone on for nearly a century—through three successive generations—the houses have spread beyond the limits of the old boroughs and cities. In 1835 a great change was made in their constitution; and the limits of many were enlarged by the adoption of the new boundaries settled for purposes of parliamentary elections, after an inquiry by commissioners into the circumstances of each place. The affairs of municipal boroughs are administered by *councils* elected in the several wards; by a mayor and aldermen, elected out of the council; auditors and assessors, elected by the burgesses; a treasurer and a town-clerk, appointed by the council. Such functionaries exist in every reformed borough; others may be appointed. Justices of the peace may be appointed by the Queen; so may salaried police magistrates and a recorder, after petition by the council to the crown. There are coroners of the borough. The control of the police, the administration of justice, the lighting and paving of the streets, and other local functions, are in the hands of the corporations; the burgesses and householders, in many municipal boroughs, elect burgesses by majorities to serve in parliament.

During the period of nearly twenty years which have elapsed since the investigation was made into the condition of the municipal boroughs, some of the unreformed corporations have ceased to exercise any active functions, having become, in fact, either extinct or dormant, while others, although still claiming to be corporations, are municipal only in name.

By section 141 of the Municipal Corporation Act, charters of incorporation may be granted to towns, on the petition of the inhabitant householders, if Her Majesty, by the advice of the privy-council, shall think fit to grant them. At the period of the census only 19 towns had petitioned to be incorporated, and all of them, except one—Huddersfield—have received charters.

The municipal organization, as regards the number of towns, stands thus:—

England and Wales—	
Reformed boroughs named in the schedules annexed to the Municipal Corporation Act	178
Boroughs which have had charters of incorporation granted to them since the passing of that act	18
London, and the other unreformed corporate towns	89
England and Wales	285
Scotland—	
Number of cities and burghs governed by the Municipal Acts for Scotland	83
Corporate towns in Great Britain	368

The 196 reformed boroughs in England and Wales and the city of London contain 4,473,138 inhabitants. One-half of the population (2,220,542) is found in 17 boroughs; each of which contains more than 60,000 inhabitants.

It is found, also, that 102 boroughs, or more than half of the total number, contain less than 9000 inhabitants in each; and in the aggregate 472,551 inhabitants.

A population ranging from 2000 to 7000 is that most commonly met with; 87 boroughs fall under this category. 27 municipal boroughs have from 20,000 to 40,000 inhabitants; 8 have from 40,000 to 60,000 inhabitants; 7 from 60,000 to 80,000 inhabitants; 2 from 80,000 to 100,000 inhabitants; 5 from 100,000 to 200,000 inhabitants; 3 have 200,000 inhabitants and upwards.

Although some of the most populous and important towns in England have obtained charters of incorporation since 1835, several considerable places are still without a municipal organization. Amongst these may be named, in England and Wales, the metropolitan parliamentary boroughs of

	Pop. in 1851.
The Tower Hamlets	539,111
Finsbury	323,772
Marylebone	370,957
Greenwich	105,784
Lambeth	251,345
Westminster	241,611

Census Report, 1851.

III.—*Harbours, Roads, Canals, Bridges.*

Harbours.

Portsmouth, Milford Haven, and Plymouth, are the finest harbours in England, and are surpassed by few if any in the world. Of these, Portsmouth is entitled to the pre-eminence. This noble harbour is about as wide at its mouth as the Thames is at Westminster Bridge, expanding within into a capacious basin, almost sufficient to contain the whole navy of Great Britain. Its entrance is unobstructed by any bar or shallow; and it has throughout water adequate to float the largest man-of-war at the lowest tides. The anchorage ground is excellent, and it is entirely free from sunken rocks, sand-banks, or any similar obstructions. The western side of the harbour is formed by the island of Portsea; and on its south-western extremity, at the entrance to the harbour, is situated the town of Portsmouth, and its large and important suburb of Portsea. Here are docks and other establishments for the building, repair, and outfit of ships of war, constructed upon a very large scale, and furnished with every conveniency.

Portsmouth harbour has the additional and important advantage of opening into the celebrated road of Spithead, lying between the Hampshire coast and the Isle of Wight, and forming a safe and convenient retreat for the largest fleets.

Milford Haven deeply indents the southern part of Pembrokeshire. It is of great extent, and has within it many bays, creeks, and roads. The water is deep and the anchorage ground excellent; and being completely land-locked, ships lie as safely in it as if they were in dock.

Plymouth, which, after Portsmouth, is the principal naval depôt of England, has an admirable double harbour. The roadstead in Plymouth Sound has been much improved by the construction, at a vast expense, of a stupendous breakwater more than 1700 yards in length. This bulwark protects the ships lying inside from the effects of the heavy swell thrown into the Sound by southerly and south-easterly winds.

London stands at the head of the river ports of Great Britain. Considering the limited course of the Thames, there is probably no river that is navigable for large ships to so great a distance from the sea, or whose mouth is less obstructed by banks. London is mainly indebted for the unrivalled magnitude of her commerce to her favourable situation on this noble river; which not only gives her all the advantages of an excellent port, accessible at all times to the largest ships, but renders her the emporium of the extensive, rich, and populous country comprised in the basin of the Thames.

The Mersey, now the second commercial river in the empire, is more incommoded with banks than the Thames, and is in all respects inferior, as a channel of navigation, to the latter. Still, however, it gives to Liverpool very great advantages; and the new channel which has recently been discovered in the banks promises to be of much importance in facilitating the access to and from the port.

Statistics.

Bristol and Hull are both river ports. Owing to the extraordinary rise of the tide in the Bristol channel, the former is accessible even to the largest ships. The Humber is a good deal impeded by banks; but it also is navigable as far as Hull by very large vessels. The Tyne admits vessels of very considerable burden as far as Newcastle, which, next to London, is the most important shipping port in the empire.

Roads.

It was not until after 1660 that the public took an active part in regard to the highways. Turnpikes were at that time placed on the great North Road, in the counties of Hertford, Huntingdon, and Cambridge; but it was not till after the peace of 1748 that adequate exertions were made to redeem our public roads from their wretched condition. After 1760 the increasing price of agricultural produce, and the general spirit of improvement, had the most beneficial operation in this respect; and in the fourteen years from that time to 1774, no less than 452 acts were passed for the amelioration of our roads. It was then also that our inland navigation assumed an aspect of activity. The Bridgewater and Trent Canals were commenced; yet the number of canal acts which passed between 1760 and 1774 was only 19. The American war interfered considerably with public improvement; and it is only from the date of its cessation that we enter upon an active and prosperous era.

The total length of paved streets and roads in towns in England and Wales may be taken, according to a parliamentary return in 1843, at about 29,000 miles; the total length of all other roads at nearly 96,000 miles. In France the highways are under the care of government, and are kept in repair out of the general taxes, without any tolls or turnpike dues; in England they are managed by the respective counties, represented by commissioners, and no part of the expense comes out of the public treasury. It is defrayed partly by local imposts, partly by dues levied; and the local impost is discharged either by labour, or by composition money.

In consequence of the superior means of communication afforded by the numerous railways, a great reduction has taken place both in the revenue and expenditure of the turnpike trusts. The receipts from tolls and other sources in England and North Wales, which, in 1835, amounted to L.1,755,222 were reduced in 1852 to L.1,142,592, and the total expenditure for repairs, improvements, interest of debt, &c., which in 1835 was L.1,733,404, was reduced in 1852 to L.1,126,384.

The returns for turnpike roads in South Wales are kept separate according to act 7 and 8 Vict., cap. 91.

According to the general law of England every public highway is a parochial charge, and is maintained by the rate-payers of the parish in which it is situated. Consequently each road or class of roads was constructed under the authority of private legislation.

The local turnpike acts were always temporary, generally limited to 20 or 30 years, probably with the view of the loans being paid off before the expiry of the term, but as the acts were usually renewed, the debts were unpaid and undiminished for many years.

The result of this state of things has been, that the turnpike debt of England amounted, in 1849, to L.6,382,647, and the unpaid interest upon the debt amounted, for the same time, to L.1,587,010. The bonded debt on the turnpike trusts in England and North Wales in 1852 amounted to L.5,813,728, and the unpaid interest to L.1,126,507. The debt on the roads in South Wales, at the same period, amounted to L.217,020, which is payable by annuity, and will cease partly in 1875, and altogether in 1879.

Railroads.

The railroads have, since 1830, along with steam-vessels, placed the English population in direct and easy communication, not only with each other, but with the rest of the world. The total length of railways in England and Wales open for traffic at 31st December 1853, was 5811 miles. The number of passengers conveyed in that year was 84,222,961, of whom considerably more than one-half were first and second class passengers. The receipts from the goods traffic somewhat exceed those from the passenger traffic. The length of lines in course of construction at 30th June 1853 was 491, while the length authorized was 2969 miles, nearly 2500 miles being neither open nor in course of construction.

The total amount of capital and loans authorized to be raised by railway companies in the United Kingdom previous to 31st December 1852 (after deducting amounts proposed for lines subsequently abandoned), was L.356,610,456, of which L.264,165,680 had been raised: the amount raised in 1852 was L.16,398,993. The number of passengers that travelled by railway in the half year ended 30th June 1854 was 45,080,316; the amount of receipts from passengers was L.4,092,661; from horses, carriages, luggage, and mails, L.505,116; from general merchandise, cattle, minerals, &c., L.4,826,825; total for six months, L.9,424,602.

Electric Telegraph.

Connected with the railways is the electric telegraph, which is now stretched along thousands of miles across the length and breadth of the land, or sunk in the depths of the ocean, conveying intelligence between distant points with the rapidity of lightning.

In 1846, an association under the title of the Electric Telegraph Company, obtained an act of incorporation, and having bought up the various patents for electric telegraphs, they secured the exclusive right of sending intelligence through the kingdom by this means. Since then, they have been extending their operations in all directions; but great as are the advantages conferred on the country by this invention, there is reason to expect that they will be vastly increased and extended, as the instrument is capable of still greater improvements; and when the charges for the conveyance of intelligence are reduced to their proper level, the electric telegraph will be much more generally used.

Canals.

The canals of England are extremely numerous; in fact, no country except Holland can enter into competition with us in this respect. The English canals are of moderate size, being from 25 to 30, 35, and 40 feet in width, and, in general, from 5 to 6 feet in depth; the barges navigating them are very long, frequently 70 or 80 feet, on a width of 10, 12, or 14 feet; but in many cases their dimensions, at least their width, are necessarily smaller, the less frequented canals being narrower than those we have mentioned. Could the application of steam to navigation have been foreseen, the canals of England would probably have been made wider. For full details with respect to the canals of England, and the recent improvements in their construction, and in travelling by them, the reader is referred to the article NAVIGATION INLAND.

Bridges.

The principal bridges in the kingdom are the railway bridges across the Tweed and the Tyne, and the seven erected across the Thames at London, four of which have been opened since 1817. Of these, two, the Southwark and Vauxhall, are of cast-iron, the one being of three very large arches, and the other of nine arches, each of 78 feet span. The first example of an iron bridge on a large scale, either in England or any other country, was that erected in 1796 at Wearmouth in Durham, the span of which was 240 feet. The chain bridge over the Menai Straits, and the tubular bridge over the same place, are wonderful examples of engineering skill. See article BRIDGES, &c.

IV.—*Agriculture.*

Of the state of English agriculture in former ages we can form some idea from a reference to the acts of the legislature. In these we find, at a very early date, the traces of

Statistics.

that policy which expects abundance and cheapness to result from discouraging the exportation of corn. No permission to export seems to have been granted till 1394, and then only on the payment of certain duties; in 1436 some additional latitude was given, and exportation was allowed when the quarter of wheat did not exceed a price corresponding to nearly 13s. of our present money. The reign of Elizabeth was the epoch of a great rise in the prices of corn, originating, not, as was vulgarly asserted, in the "decay of tillage," but in the sudden depreciation of money, produced (as has been explained in the article CORN LAWS) partly by degradation of the coin, and partly by the influx of silver from the mines of America. The complaints of the "decay of tillage," if they express anything more than the ordinary discontent of the ignorant part of the consumers, are to be accounted for by the gradual consolidation of small farms, and by inclosing land for pasture, with a view to the exportation of wool. In these days, however, government participated in the prejudices of the people; and the general purport of the acts passed under Elizabeth and her successors was to shackle exportation and prevent a rise of price. It was not till the reign of Charles II. (1670) that the exportation of corn was exempted from taxation; and it is from 1689 that we are to date that fundamental change in our corn laws which encouraged exportation by a bounty.

Clover, turnips, and potatoes were introduced into England in the seventeenth century. In the *Improver Improved*, published by Blythe in 1649, we find the first traces of what may be termed the modern system of husbandry; that is, of a rotation of crops, and of the occasional substitution of green for culmiferous crops. But the practice, though thus early introduced, and though it lies at the foundation of all good husbandry, made but little progress for a very long period. The writings and the example of the famous Jethro Tull, in the early part of last century, notwithstanding he carried his theory to an excess, did much to introduce the practice of drilling, and had a very favourable influence on agriculture. Nothing, however, did half so much to accelerate the march of improvement, as the wonderful increase of manufactures and commerce, and consequently of the town population, subsequently to the peace of Paris in 1763. The greater number, and still more the improved circumstances, of the people, occasioned, in particular, a very great increase in the demand for butchers' meat. And it is to this circumstance that we are mainly indebted for the extraordinary improvements which have been made during the last sixty or seventy years in stock husbandry. But the indirect influence of the augmented demand for butchers' meat has been equally conspicuous, and has proved of the utmost advantage to arable husbandry, inasmuch as it caused a corresponding increase in the demand for green food, that is, for turnips, clover, &c. This did incomparably more than anything else to introduce that intermixture of green and culmiferous crops which is so essential to good husbandry; and it was the real cause of the greatest of all agricultural improvements, namely, the substitution of turnips for fallows on all light lands. This has increased the productive power of the soil in a degree not easy to be conceived; and, coupled with the frequent substitution of beans for naked fallows on stiff clay lands, has in all probability more than doubled the available raw produce of the kingdom.

For a lengthened series of years England exported large quantities of corn. But notwithstanding the vast additions made to the supplies of corn by the improvements alluded to, the still greater increase of wealth and population, after occasioning, first a diminution, and next a cessation of exportation, has for many years past rendered a large importation necessary to meet the consumption of the country. It has been supposed by some that this change was owing to the alterations effected in the laws with respect to the importation of corn in 1772; but we have elsewhere shown that there is no ground for any such opinion. (See CORN LAWS AND CORN TRADE.)

Statistics.

The principal crops cultivated in England and Wales are wheat, oats and beans, barley and rye, turnips and potatoes, with clover, hops, flax, &c. It is to be regretted that no estimate, derived from authentic returns, has been formed on which much reliance can be placed, either of the extent of land under different crops, or of the average product per acre. Mr Caird, in his work on *English Agriculture* p. 522, gives the following estimate as the result of his survey of England in 1850–51 of the extent of land under the different species of crops, and in fallow, in England:—

	Acres.
Wheat	3,416,750
Barley and rye	1,416,750
Oats and rye	2,000,000
Beans and pease	1,139,000
Clover	2,277,750
Roots (turnips, mangold, potatoes, &c.)	2,116,750
Hops, gardens of all sorts, &c.	150,000
Fallow and rape	1,300,000
	13,817,000

An estimate of the extent of land in England and Wales under the principal descriptions of crops in 1852–53, with the average rate of produce per acre, the value of such produce, &c., will be found in our article CORN LAWS AND CORN TRADE. The recent agricultural reports of Scotland have shown that, as regards that country, the previous estimates of the extent of land under the different kinds of crops were very far from being correct. The result of these reports proves the great difficulty of arriving even at an approximation to the truth in such estimates, and that it is only by authentic returns that accuracy on that and similar subjects can be obtained; and it is by no means creditable to the country, that till this day no effectual measures have been taken to procure authentic information as to the amount of food which England can supply for the subsistence of her population; but after the example which has been set by the rural tenantry of Scotland, it is to be hoped that another year will not be permitted to pass till measures have been taken to procure equally satisfactory returns of the agricultural capabilities of England. In the meantime, we make the accompanying statements upon the most reliable estimates we have been able to procure.

Cattle.

Various estimates have been formed of the number of cattle in England and Wales; but judging from the best authorities, they may be said to amount to about 4,500,000. By systematic breeding, turnip feeding, and other means, the quality of the cattle has been much improved even within the present century. The principal breeds are the North Devons, Herefords, Suffolk duns, and the Teeswater short-horns.

Horses.

M'Culloch estimates the number of horses in Great Britain at from 1,300,000 to 1,400,000. The English horses are justly celebrated for their size and condition; and excite the admiration of foreigners who are accustomed to the miserable horses abroad. The famous London drays are reared in the fens and rich pastures of the midland counties. The Suffolk punches are compact, hardy, and very active, and have been long reared in the county from which they take their name. Another well-known English breed is the Cleveland bays, which are properly carriage horses, but in their native district they are largely employed in fieldwork.

Sheep.

The number of sheep in England and Wales may be estimated at about 27,000,000. The distinct breeds and varieties are very numerous. The most important and the most widely diffused are the Leicesters, which constitute the staple breed of the Midland counties. The Lincolns were at one time large ungainly animals, but by crossing them with Leicesters the character of the breed has been

Statistics. entirely changed, and it is now, in fact, a variety of the Leicester with larger frame and heavier fleece than the pure breed. This variety is reared in immense numbers on the wolds and heaths of Lincolnshire. The black-faced or heath breed is found on the mountainous parts of Yorkshire, Lancashire, Cumberland, and Westmoreland, being better adapted than any other for elevated pastures. The chief of the other breeds are the Cotswolds, New Oxfords, Teeswaters, Kents, South Downs, and Dorsets, whose names indicate the districts in which they chiefly prevail.

Merinos were introduced about the beginning of the present century, and were imported in large numbers after our alliance with Spain in 1809. Opinions differ in regard to their utility, the carcass not having answered so well as the fleece. Considerable advantage, however, has been derived from crossing them with our own breeds. The annual produce of wool is calculated at 550,000 packs of 240 lbs. each.

The great pasturage counties are Leicester, Northampton, Lincoln, and Somerset. Of the counties producing butter and cheese, the principal are Cheshire, Gloucestershire, and Wiltshire. But notwithstanding the immense supplies of these articles produced at home, the demand is such, that at an average we import about 130,000 cwts. a-year of foreign butter, and about an equal quantity of cheese, principally from Holland. The average annual importation of Irish butter into England cannot be precisely ascertained; but in 1825 it amounted to 425,000 cwts., and since that time has much increased.

Produce of grass-lands.

The produce of grass lands may be determined in two ways; either by ascertaining the quantity and value of the different articles annually produced, or by taking a general rough average value per acre. The former would be the most satisfactory mode; but the details are too numerous and too loose to admit of their being put forward with much confidence. We believe, however, that the annual value of the various products derived from pasture land may be estimated, on an average, at about L.3, 10s. an acre, being equivalent, upon 17,000,000 acres, to L.59,500,000.

Rent.

The rent of land in England and Wales is usually estimated at from one-fifth to one-fourth of the value of the produce, which, taking the latter at L.130,000,000, would give from L.26,000,000 to L.32,500,000, or L.29,250,000 at an average, as the rent of the kingdom. We incline to think that this is pretty near the real amount. In 1810 the rent of England and Wales, as ascertained by the property-tax commissioners, was L.29,500,673; and the general opinion seems to be, that the rent at present is about equal to the rent in 1810; the rise that took place in the four succeeding years having been balanced by the subsequent fall. Since 1851 the rent of land has been gradually rising.

Farmers' capital, profits, &c.

The capital employed in the cultivation and stocking of the land in England cannot be estimated, at the present prices, at less than from L.6 to L.7 an acre; which, excluding waste land, would give a total capital of from L.172,494,000 to L.201,243,000. It appears from the property-tax returns for 1810, that the profits made by the occupiers were almost identical with the rent. But it will be observed, that besides the interest on, or return for, the capital employed in farming, the profits in question included all that the occupiers received on account of their trouble in superintendence, and for the greater part of their own labour and that of their families.

Size of farms.

We have already, in the article Agriculture, treated of the points of superiority in our husbandry over that of the Continent; ascribing it to various causes, and to none more than the medium size of our farms, which differ equally from the large unmanageable tracts held by Polish noblemen, and the diminutive occupancies so common amongst the French peasantry, particularly since the Revolution.

The size of farms in England is greatest in the best-cultivated districts, that is, in the counties to the east of the metropolis, viz., Kent, Essex, Suffolk, and Norfolk, and in the various chalk districts. Farms are also extensive in Northumberland. In these counties the engagements of farmers are for larger sums than in East Lothian, Berwickshire, or any part of Scotland, rents being frequently from L.800 to L.1200 and L.1500 a-year. In more retired districts, particularly in Cumberland, Westmoreland, and Wales, the occupancies, whether farmed or held in property, are in general very small; and an average of all the farms of England and Wales would not much exceed L.150 a-year.

By the census of 1851, it appears that there are 285,936 farms in Great Britain, of the average size of 102 acres; in England and Wales the farms amount to 225,318, or 111 acres on an average; in Scotland 56,650 farms have an average size of 74 acres. The average English farm, it will be seen, differs little in size from the Hyde of the Anglo-Saxons, which according to some estimates contained 100, according to others, 120 acres. Half of the territory of Great Britain, two-thirds of the English territory, and one-fifth part of Scotland, are thus asserted to be occupied as farms. The rest remains unaccounted for; and the greater part of it is probably hill, moor, marsh, or other less fertile ground; as well as water and land now entirely sterile. The hill pastures are not included in the farms to which they are attached.

Two-thirds of the farms in Great Britain are of a size under 100 acres: or, taking the *exact proportions, in a thousand farms* 672 are under 100 acres; 187 are 100 and under 200 acres; 137 are 200 and under 1000 acres; and 4 are 1000 acres and upwards. The proportions to 1000 farms in England and Wales are 638 under 100 acres; 205 of 100 and under 200 acres; 154 of 200 and under 1000 acres; and 3 of 1000 acres and upwards. In Scotland there is at once a great excess of *small* and of *large* holdings. There are 360 farms in Scotland, and 771 farms in England of 1000 acres and upwards. There are 142,358 farms in England, and 44,469 farms in Scotland, each of which is under 100 acres. In England and Wales the *large holdings* abound in the *south-eastern counties* and in the *eastern counties;* the *small farms* in the *north-midland counties,* in *Yorkshire,* in *Wales,* and in the *north-western counties,* comprising *Lancashire* and *Cheshire.* Nearly all the farms (947 in 1000) in the Islands of the British Seas are small, if farms under 100 acres can be so designated.

Number of Farm Holdings of different Sizes in Great Britain.

Total....................	283,378	223,271	56,150	3,957

Note.—The size of 2558 farms in Great Britain was not stated.

The farmers who returned themselves as actually occupying land in England and Wales amounted to 225,318, of whom 133,620 had 665,651 labourers in their employ on the census day; 40,650 farmers, employing 5 or more labourers, had two-thirds or 467,709 of the agricultural labourers; 16,501 farmers, each having 10 or more, employed 311,707 of these labourers.

Leases.

Leases in England are, with the exception of particular districts, granted for seven years only; when the term is longer the case is peculiar, and applies to land which evidently requires very extensive improvement. But by far the largest portion of England is held by tenants at will, or by tenants holding only from year to year. There is in such cases something like an assurance, on the part of the landlord, that the tenant shall not be removed for a certain number of years, or that otherwise the improvements shall be considered and allowed for. When a tenant holds from year to year there is a written agreement, with specified covenants, the tenant being subjected to fines in the event of a deviation from them. Both methods are highly injudicious; and it is in the prevalence of these that we are to look for the backward state of agriculture in many of our finest counties. No class of men have more liberality than the English landholders; but it would be in vain to expect a tenant to lay out much capital on the improvement of a farm of which his tenure comes to an end in seven years, or may be disturbed by the commission of a trespass or the occurrence of a death. A tenant so situated loses the habit of reflecting on improvements, and even of carrying into effect those which he is aware would in time be advantageous. If he succeed in saving money, he is much more likely to place it out at interest than to employ it in his own business.

Comparison with Scotland and the Continent.

In Scotland the rent bears a higher proportion to the gross produce than in England, being in general not less than from one-fourth to one-third. This is owing not certainly to greater capital, and still less to superior soil, but to an exemption from tithe, the use of long leases, and partly, and principally, we believe, to greater economy, particularly in horses. It is in tillage, not in pasturage, that the Scotch farmers lay claim to superiority. On comparing English agriculture with that of the Continent, we find that our chief superiority consists in machinery and in live stock. Thrashing machines are little used on the Continent, and all iron manufacture is of inferior quality. In regard to live stock, the countries which approach nearest to us are Jutland, Holstein, Holland, Flanders, and Normandy; all evidently indebted for their extensive pasturages to the vicinity of the sea: in the interior of the Continent, pasturage is, in general, very indifferent. Even in these maritime provinces, the cattle, though frequently large, are not fattened in the same gradual manner as in our grazing counties; and the meat, consequently, is not of equal flavour. In horses the inferiority is more apparent to the eye, and holds both as to size and shape. Flemish horses are large, but heavy; whilst the Norman breed, though capable of much labour, is small in size when compared with the English. Nowhere are horses seen of such bulk and strength as the drays in London. If they are, as is supposed, of foreign origin, they have greatly surpassed the primitive stock, since neither the Netherlands nor Holstein can now match them.

We cannot close this part of our subject without a few remarks on the connection between the state of our agriculture and the extent of our financial burdens. Those who compare the heavy pressure of our taxes with the lighter burdens of our Continental neighbours, have in general the satisfaction of finding some counterpoise in the superior dexterity of our people, and the productiveness of our capital. This holds true in regard to our navigators, our merchants, and our manufacturers; and it holds in agriculture in regard to grazing, because in grazing little personal labour is requisite, whilst capital and active habits of business are of the most beneficial operation. But, in the department of tillage, much remains to be done ere England can claim any great superiority. Farms are yet too small in more than two-thirds of England, and leases are generally too short. The course of husbandry is frequently injudicious, the ploughs are on a bad construction, and there exists a gross misapplication of animal strength. However light the soil, and however strong the horses, it is still customary to put three, four, and frequently five, in a plough, throughout almost all the south, the west, and south-west counties. These are the main causes of the comparative unproductiveness of our finest counties.

The quantity of land still remaining uncultivated in the shape of wastes and commons is a frequent topic of animadversion; persons unacquainted with agricultural calculation calling loudly for this island being brought into culture, whilst the landed interest object to passing a general inclosure act, or, in other words, to giving unlimited scope to speculative cultivation. We by no means participate in the apprehensions of the latter; but we would abstain from giving any artificial stimulus to this, more than to any other branch of industry. Let the progress of inclosure be regulated by the gradual increase of our population, and the discovery of better methods of turning such land to account. No benefit can be derived from applying to this purpose any more capital than would go to it voluntarily; and every experienced farmer is aware that the best prospect of profit lies, not in reclaiming new soils, but in bestowing further labour and expense upon the land already under culture.

V.—*Mines—Quarries—Iron, Copper, Tin, and Salt Works.*

In regard to minerals, England does not yield to any country in Europe in natural abundance, and takes the lead of all in the extent to which these rude treasures have been converted to purposes of utility. Our great superiority lies in our coal-mines, which are not only more productive, but much more advantageously situated, than those of the Continent. To the mines along the coast a ready conveyance is afforded by our insular position, and to those in the interior by our inland navigation. The consumption of coal in England for domestic use has been estimated at 20,000,000 tons annually. Large as this quantity is, and larger as it must be when we add to it the vast consumption of manufactories, such as iron-works, copper-works, salt-works, glass-houses, and the like, there is no reason to apprehend the exhaustion of this precious mineral; the depth of the coal beds being very great, and the extent of ground containing them amounting to many hundred thousand acres.

Statistics. The principal coal-beds lie in Northumberland, Durham, Derbyshire, Staffordshire, and Glamorganshire. The ports for shipping coal in large quantities are Newcastle, Sunderland, and Hartlepool. The motive of the tax on coal exported to foreign countries was thus neither an apprehension of eventual scarcity, nor even a calculation of revenue, so much as a dread of giving our Continental neighbours the means of rivalling our manufactures. Coal is not wanting in France and Germany, but the mines are at a distance from water carriage, and as yet very imperfectly wrought; whilst for the purpose of domestic fuel the inhabitants give a preference to wood. After various changes, the export duty on coal was totally abolished in 1850.

According to the census of 1851 the total number of persons engaged in the coal trade is 239,459.

In 1853 the exports of coal to foreign countries, according to the real or declared value, amounted to L.1,602,762. See articles COLLIERY and COAL TRADE.

Quarries. In quarries, whether of stone or slate, England is not rich, particularly the eastern half of the kingdom; and hence the almost universal use of brick in ordinary buildings. It is not till the traveller reaches Durham that he finds stone commonly used. In the northern counties quarries occur frequently; in the southern, those of Portland and Bath are the most considerable. Still the annual profits of the whole are small.

Iron mines and works. No branch of our industry has increased more rapidly in the present age than our iron-works. A century ago it was computed that we required an annual importation of 20,000 tons of foreign iron; an importation which for many years seems to have been on the increase, so as, after the middle of last century, to carry the quantity required to 30,000, 40,000, and even to 50,000 tons. This supply was brought to us from Sweden and Russia, and, though burdened with duty, it was in quantity more than double our native produce. But fortunately, after the year 1780, discoveries were made which increased greatly our supply at home. Bar iron had been manufactured in England, as on the Continent, with charcoal fuel only, coal being deemed inapplicable to that purpose. Under that impression, the rapid consumption of the wood in the neighbourhood of our different iron-works had necessitated a removal, at a great expense, of materials from one spot to another, and was on the point of causing an alarming decay in the business, when our iron-masters, after long perseverance, succeeded in applying coal to their manufacture. They had to contend with various prejudices, particularly the supposed inferiority of iron so made; but, in the course of years, the manufacture acquired such an extent that there were, in 1805, 220 blast-furnaces, making 250,000 tons of pig iron.

The transition from war to peace did a good deal of injury to some branches of the iron trade; but the effect of the change was not of long duration, and the production of iron has since been astonishingly increased. In 1820 the produce was calculated at 400,000 tons. The excitement and speculation of 1824 and 1825 had a wonderful influence on this department. According to careful inquiries made at the time, the furnaces at work in England and Wales in 1827, with their produce, were as under:

Staffordshire	95 furnaces	216,000 tons.
Shropshire	31	78,000
South Wales	90	272,000
North Wales	12	24,000
Yorkshire	24	43,000
Derbyshire	14	20,500
Totals	266	653,500

Owing to the failure of various railroad and other projects set on foot in 1825 and 1826, the supply of iron seems to have greatly exceeded the demand; and there was a very heavy fall of prices in 1828, 1829, and 1830, and again in 1850 and 1851. But within the last two years prices have again risen; and the iron trade is at this moment in a state of great activity. The produce of the various furnaces of England and Wales may be estimated at nearly two millions of tons.

Account of the number of Furnaces, and of the Quantities of Iron produced in Great Britain in 1825 *and* 1848.

	Total Furnaces in 1825.	Produce of Iron in 1825.	Total Furnaces in 1848.	Produce of Iron in 1848.
		Tons.		Tons.
South Wales	107	230,412	196	706,680
North Wales	14	17,756	11	16,120
Northumberland	...	...	36	100,000
Yorkshire	34	39,104	28	66,560
Derbyshire	19	22,672	30	95,000
Staffordshire	107	182,156	158	385,840
Shropshire	48	89,596	34	88,000
Scotland	25	33,540	130	550,000
Totals	354	615,236	623	2,008,200

The quantity of iron of all kinds manufactured and unmanufactured, exported in 1852, amounted to 1,035,884 tons, besides 25,289 tons of cutlery of the declared value of L.2,691,697. Now that the railways are nearly completed, it might have been expected that this would have caused a stagnation in its manufacture; but iron is now so extensively used in the construction of steam-vessels, that the demand has been maintained. For more ample details, the reader is referred to the article IRON.

Copper. Copper-mines have long been known in England, but they were wrought with very little skill or effect until towards the year 1700. Even at that time the annual produce, after smelting the metal from the ore, was only a few hundred tons of copper; and it hardly exceeded 1000 tons annually down to the middle of last century. From that time forwards the increase became considerable, as well in Cornwall as in Devon, North Wales, and Derbyshire; in all of which copper-mines were discovered and wrought. In North Wales there were two mines, Parys and Mona, which, for some time after the year 1780, yielded annually a large quantity of ore, but they are no longer so productive; the mines of Devon and Derbyshire continue to be wrought, but the great product is from Cornwall; the mines of Cornwall and Devon in 1853 yielded 181,969 tons of copper ore, the metal obtained from which, at the rate of $6\frac{1}{2}$ per 100, produced 11,823 tons of standard copper, which, at the average rate of L.140 per ton, amounted to L.1,655,220. It is the Welsh collieries which afford to Cornwall, as to Devonshire, the means of smelting; and as the ore is less heavy than the coal required for this operation (one ton of ore requiring from two to two and a-half tons of coal), the practice is to convey the ore in vast quantities to Wales, particularly to Swansea. In this, as in other minerals, France is greatly behind England. She has various copper-mines, but her coal-mines, at least those hitherto wrought, are at too great a distance to make such undertakings profitable; and she consequently requires an annual importation from England.

In 1854 there were exported of brass and copper manufactures 1,851,689 cwts., of the value of L.1,761,878.

Tin. Cornwall is also the great seat of the tin-mines of England. A century ago the average produce of our tin-mines hardly exceeded 1500 tons; it may now be estimated at about 5000 tons a-year. From abroad we receive tin principally from our Indian possessions, Holland, and the United States. Of this we imported, in 1853, 49,740 cwts. The value of tin unwrought, and in plates exported in 1854 was L.1,307,246.

Statistics.

Lead. The lead-mines of England are principally in Cumberland, Northumberland, Derbyshire, Flintshire, and Salop. In 1852, England and Wales produced 80,790 tons of lead ore, and 57,621 tons of lead. Black lead is found in Cumberland, in the romantic district of Borrowdale. The mine was formerly opened only periodically, in order that the market may not be overstocked; but for a considerable number of years past it has been constantly open.

There is no country so well supplied as England both with brine springs and beds of fossil or rock salt. The brine springs are found in Cheshire, in the southern part of the county, in places contiguous to the river Weaver, and at Droitwich in Worcestershire. The beds of rock salt, which are of great thickness, were discovered in the vicinity of Northwich and Lawton. The greater part of the salt produced is obtained from the brine springs. Formerly considerable quantities were produced by the evaporation of sea water, but since the abolition of the duties most of the works appropriated to this manufacture have been abandoned. From the brine springs it is obtained (see the article CHESHIRE) at the rate of one gallon of solid salt from four gallons of liquid, whilst common sea water does not yield above one in twenty-eight. The consumption of salt in this country is immense. Necker estimated its consumption in those provinces of France which had purchased an exemption from the gabelle (*pays francs redimées*) at about 19½ lbs. (Eng.) for each individual. (*Administration des Finances*, tome ii. p. 12.) From all that we have been able to learn on the subject, we believe that the consumption of the people of this country may be estimated a little higher, or at 22 lbs.; the difference in our food and habits, as compared with those of the French, fully accounting for this increased allowance. On this supposition, and taking the population of Great Britain at 21,000,000, the entire consumption will amount to 462,000,000 lbs., or 206,250 tons.

Exclusive of this immense home consumption, we annually export about 18,000,000 bushels, which, at 56 lbs. a bushel, are equivalent to 357,143 tons. The Americans are the largest consumers of British salt.

The cheapness of this important necessary of life is not less remarkable than its diffusion. Its present cost may be estimated, at a medium, at from 14s. to 16s. a-ton.

Salt has been at all times a favourite subject of taxation. In this country it was first taxed in the reign of William III. In 1798 the duties amounted to 5s. a bushel, but they were subsequently increased to 15s. a bushel, or about forty times the cost of the salt. So exorbitant a duty was productive of the worst effects, and, in particular, occasioned a great deal of smuggling. The duty having in consequence become exceedingly unpopular, was finally repealed in 1823.

VI.—*Fisheries.*

At present our space allows no more than a brief notice of the principal branches of our fisheries.

Mackerel. The mackerel fishery is strictly English, and is carried on with great vigour on the coasts of Kent and Sussex, in May, June, and July. Large as the supply is, it would still admit of augmentation; and herrings also might be caught in vast quantities on the coast of Kent in October and November. The desideratum with the fishermen is not so much a high price as a certain market; and the most effectual way to procure that is, to quicken, by every possible means, the conveyance to London, which has been accomplished by the employment of steam-boats and railways.

Pilchards. The pilchard fishery takes place chiefly on the coast of Devonshire and Cornwall, and, though subject to great fluctuations, as well from the seasons as from our political situation relatively to the Continent, forms on the whole an important branch, employing a number of seamen both in catching the fish and in carrying it to foreign markets. Its season is generally from June to September.

Statistics.

Herrings. The herring, the most important of all our fisheries, is happily now in a state of rapid extension. It formed, during the seventeenth century, the great employment of the Dutch seamen, and was contemplated by their neighbours with very jealous eyes. Accordingly, in the reign of Charles II., particularly after the rupture with Holland in 1672, several acts were passed for the encouragement of our fishermen, and in a spirit of hostility to the Dutch. The subsequent accession of William to our throne, and the long friendship between the two countries, relaxed the exertions of government; and it was not till after the peace of 1748 that a large bounty was given on the tonnage of the busses, or masted vessels, so employed. Still our fishermen proved unable to compete with the experience and patient perseverance of the Dutch, and it was found necessary to raise the bounty from 30s. to 50s. per ton. This had the desired effect, and the number of busses increased; but the additional 20s. being withdrawn in 1771, the fishery again declined. The American war, and, subsequently, the wars of the French revolution, proved extremely adverse to its extension. At last, in 1808, an act was passed carrying the bounty to L.3 a ton on the busses, with a further grant of 2s. per barrel on all herrings caught, whether in busses or boats. This act was further confirmed in 1815, and the bounty per barrel raised to 4s. with the qualification that the herrings should be gutted before curing.

In consequence of the encouragement thus afforded, the fishery was materially extended; but this was effected at a great expense, and had, besides, several bad consequences. The bounties given by government tempted persons without capital or skill to enter into the business, to the great injury of the regular fishermen; so that notwithstanding the extension of the business, it was found, as is invariably the case with all departments carried on by means of a bounty, to be in a very unhealthy state. In consequence partly of the circumstances now stated, and partly in consideration of the real and substantial relief given to the fishery by the abolition of the duties on salt, it was resolved gradually to withdraw the bounty, which totally ceased in 1830. And we are happy to have to state, that though the fishery fell off whilst the bounty was in the course of being withdrawn, it has since been materially increased, and is now in a better situation than at any former period. From the year 1811 to 1830, the year when the bounty ceased, the greatest number of barrels cured in Great Britain was 442,195; and in the year ending December 1853, they amounted to 778,039, the largest number cured in any previous year. The quantities cured in each year vary considerably according to the abundance of the shoals that appear upon our coasts in different seasons; but since 1838 the annual quantity cured has never fallen below 500,000 barrels, while for the 25 previous years they would scarcely average 300,000. In 1851 there were exported 239,330 barrels of the declared value of L.228,885.

Cod Fishery. This fishery is next in importance to that of the herring. It is carried on in a great variety of places contiguous to the British shores. The finest fish is caught round the edges of the Dogger Bank, but within these few years London has been principally supplied with cod taken between Yarmouth and the Nore. The fisheries in the neighbourhood of the Shetland and Orkney islands are productive and valuable, but the great bank of Newfoundland is the principal station of the distant cod fishery. About 2000 men are employed in the sole fishery.

Salmon. Salmon are rarely caught except in estuaries or rivers, which in most instances are private property. It is found in most English rivers, but in such small quantities as to make the fishing an object of little consequence.

England is chiefly supplied from the fisheries in the Scotch

Statistics.

and Irish rivers, but from some cause or other there is a growing scarcity in this fish, probably from the weirs or salmon traps placed in the rivers and estuaries in the way of the fish when ascending the rivers to spawn.

Whale fishery.

Greenland was first discovered by the English; but in this, as in other branches of navigation, we long allowed the Dutch to take a lead. It was not till after 1750 that, government having granted a bounty of 40s. a ton on every vessel employed in the whale fishery, a considerable increase took place in this branch.

In 1750, the vessels employed were only nineteen; in 1756 they had increased to sixty-seven. The war soon caused a decrease of one-half; but at the return of peace in 1763 this fishery revived, and in 1770 the vessels employed amounted to fifty, in 1773 to fifty-five, in 1775 to ninety-six. The American war again caused a decrease, and in 1782 the vessels so employed were only thirty-eight. In 1784 they increased to eighty-nine, and in 1785 to 140. After this they exceeded 200 annually till 1793; but the long continuance of the late wars reduced them below half the number employed previously. In 1852, the whale fishery employed ships, of the aggregate burden of 16,113 tons

The Newfoundland fishery has been considerable for fully a century past. As a nursery for seamen, it is accounted of such consequence as to have formed the object of a specific article in most of our treaties of peace. The fish caught, particularly in time of peace, is sent less to Britain than to the Catholic countries in the south of Europe; a market subject to all the interruptions attendant on a change of political relations. The number of vessels employed in this fishery at different times was as follows:

In 1731	70
1764	140
1774	254

The American war caused a diminution; but in

1784 the number was	236
1785	292

At this rate the fishery continued until the war of 1793, after which, particularly after our rupture with Spain in 1797, it fell off greatly; the fishing vessels in 1798 being only 140.

The continuance of war, and the aggrandisement of the French in Italy, occasioned additional depression; so that in 1810 the number of our vessels employed at Newfoundland did not exceed ninety-two. The peace seemed to promise a revival of this important nursery of seamen; and in the year 1816 the number of vessels which arrived in Newfoundland was 795, manned by 6000 seamen (*Report of Committee* in June 1817, p. 7); but the trade, both then and in 1817 and 1818, proved unprofitable, in consequence of indifferent seasons, of the high duty imposed on fish imported in British vessels into Naples, and of the competition of the French fishermen, supported by a high bounty from their government. The total value of fish exported from the British colonies in North America in 1851 was L.827,738.

It is matter of surprise to foreigners that a maritime nation should not have more effectually cultivated this great means of facilitating the support of our population. The ample supply which might have been afforded by the Nymph Bank, on the south-east coast of Ireland, has been avowedly neglected; and it was only in 1818 that we made the discovery of a bank of almost equal productiveness in the vicinity of Orkney.

Fish is little known to the mass of the people in our inland counties, though the facilities of transport afforded by the railways is gradually distributing it in larger quantities. London has always been amply supplied. Mr Mayhew, in his pamphlet on *London Labour and the London Poor*, estimates the weight of fish annually consumed in London at above 450 millions of pounds, besides an enormous quantity of shell-fish. Calculating the fish of all kinds at 3d. per lb. on an average, the amount would exceed five millions sterling. See the article FISHERIES.

VII.—*Manufactures.*

Woollen manufacture.

In this great department of our productive industry we begin with woollens, which, although no longer the largest of our manufactures in point of exportation, nor even in the value annually made, is entitled to the first place from the priority of its establishment, as well as from the substantial basis on which it rests. England, from the extent of her pastures, abounded in wool from a very remote age, and the inhabitants were doubtless capable of manufacturing it into rude clothing; each weaver working in his separate cottage, and with very little aid from machinery. In the twelfth and thirteenth centuries we appear to have had only the most humble fabrics, and to have imported all cloth of finer texture; sending abroad our wool in quantities to Flanders, a country the inhabitants of which were at that period much further advanced than the rest of Europe, with the exception of Italy. It was in the middle of the fourteenth century that a better system was introduced. Flemish manufacturers were invited over to England, and improved greatly the quality of our home-made woollens. The seats of this branch of industry appear at that time to have been Kent and Essex; afterwards Gloucestershire, and subsequently the West Riding of Yorkshire. It occupied at first the southern and more improved districts, and spread afterwards to the northward, on account of the cheapness of labour, the abundance of coal, and the convenience of waterfalls for the machinery. The general character of the woollen manufacture of England has been that of slow progress, but of little fluctuation; the latter evidently a consequence of its depending more on home consumption than on exportation. In the long period from 1700 to 1780, the exports experienced a regular but not rapid rise, amounting in the latter years to about L.3,500,000, whilst our home consumption increased in proportion to our augmenting numbers. More recently the manufacture has been materially improved by the adoption of various important mechanical inventions in the spinning, weaving, and dressing departments. On the whole, however, improvement has been much less rapid in it than in the cotton manufacture; so that whilst our exports of cotton stuffs and yarn have increased beyond all precedent, those of woollens have been comparatively stationary.

As we shall enter fully, in the article WOOLLEN MANUFACTURE, into the details connected with its history, progress, and present state, it would be useless, even if our limits permitted, to anticipate these here. We shall only observe, therefore, that the entire value of the manufacture is estimated at about L.25,000,000.

According to the census of 1851, there were employed in the various branches of the woollen manufactures 176,131 males and 118,642 females.

By far the largest proportion of the raw material of the manufacture is the produce of our own flocks; but for many years past we have imported large quantities. Previously to 1800 our average imports did not exceed 3,000,000 lbs., mostly brought from Spain, the wool of which long maintained a high character. In 1800 our imports increased to 9,000,000. Since then they have gone on increasing, till, in 1852, they reached 93,761,458 lbs., of which 43,197,301 lbs. came from our own dependencies in Australia.

In 1831, the exports of woollen manufactures amounted to L.5,232,013. Since then they have annually increased, till, in 1852, they reached L.8,730,934.

For an account of the prices and qualities of wool, &c., the reader is referred to article WOOL in this work, or in M'Culloch's *Commercial Dictionary*.

Statistics.

Cotton manufacture

Our cotton manufacture is entitled to the greatest attention on different accounts. Of all our manufactures, it affords the largest export, and exhibits the most rapid improvements in machinery. Its introduction, though not remote, is less recent than is commonly supposed. It appears to have taken place early in the 17th century, when it was established at Manchester; but it was long conducted upon a very limited scale. The raw material, imported at first only from the Levant, in particular from Smyrna, began after 1660 to be supplied by our West India colonies. The quantity imported amounted, about the year 1700, to 3500 bales; but, increasing with the extended cultivation of our colonies, it averaged, about the year 1720, something more than 7000 bales. From the colonial conquests of the war of 1756, our import of cotton received a further augmentation; but the manufacture increased very slowly, a great part of our cotton being re-exported to Holland, for the supply of Dutch and German weavers. It was not till after the peace of 1763, and the invention, first of the carding machine, and next of the spinning jenny, that this manufacture became considerably extended. In 1775, the average import of cotton approached to 18,000 bales. A variety of inventions, unequalled in the history of manufacturing industry, were now made (see our article on the COTTON MANUFACTURE), which gave an astonishing stimulus to the business. Fine calicoes and muslins were introduced; the workmen were withdrawn from their detached dwellings, and collected into large factories; and the price of the finished article experienced a reduction, notwithstanding a rise in the raw material, and in the wages of labour. The period which followed the peace of 1783 is perhaps unexampled for the reduction of price, and the consequent extension of sale that took place in regard to cotton goods. The commencement of hostilities in 1793 gave a pretty severe shock to the business; but the improvements in machinery continuing, the manufacture soon recovered, and has gone on increasing, under many vicissitudes, with a rapidity unparalleled by any other business, either in this or any other country. Neither does there seem to be any ground for fearing that this progress will be speedily checked. On the contrary, our superiority in all that contributes to the advancement of the manufacture is so very decided, that, provided the public tranquillity be preserved unimpaired, we have nothing to fear from the competition of others.

The reader is referred to the article COTTON MANUFACTURE in this work, for an account of the rise and progress of this great branch of national industry, and for tabular statements, exhibiting the present magnitude and importance of the trade, the sources whence the raw cotton is derived, and the foreign markets for the finished articles.

Hardware.

We have already noticed the surprising increase in the produce of our iron mines since 1780. This increase of the raw material, joined in some cases to the command of coal in the vicinity, and in all to a facility of conveyance of coal and iron by canals and railroads, has, in the last fifty years, given a great extension to our hardware manufacture. In it we take the lead of foreigners as decidedly as in our cottons; and if the ratio of increase has not been altogether so rapid, it is owing, not to inferior ingenuity in the workmen, but to radical differences in the two manufactures. In no department has the subdivision of employment been carried to so great a length; in none are its effects in cheapening production so conspicuous. Birmingham and Sheffield are the two great workshops for our hardware; the latter is confined to iron and steel, whilst in the former, not only iron and steel, but copper and brass, constitute the materials of labour. Sheffield fabricates articles which are less for ornament than utility, and which possess in general a certain bulk, such as grates, spades, sickles, files, knives, fenders, fire-irons; whilst in Birmingham there is, in addition to articles of solidity, a surprising variety of toys, fancy goods, and petty manufactures; each trifling when considered separately, but the whole forming an aggregate of great value. The most insignificant of these, such as a brass cock or a button shank, passes through a number of hands, and each artisan performs only a single operation. He thus acquires an extraordinary dexterity in his limited department, and in the course of a day despatches several hundred, perhaps even a thousand articles, through his particular stage; the result of all which is, that the price, when sold in quantities, is incredibly low. Another and very interesting feature in the situation of Birmingham, is the populousness of its neighbourhood. Yet in none of our large towns is living less expensive; an advantage owing partly to the abundance of coal, partly to the ready supply of milk and vegetables from the wide space occupied by the population.

The nail trade is carried on, not in the town of Birmingham, but in a part of the surrounding district. It is computed, by the census of 1851, to employ, in England and Wales, 16,965 males, and 9976 females, of whom 7625 are under 20 years of age; for even this heavy article admits of a subdivision of employment, which lightens the labour, and enables the workman to avail himself of the aid of his family. Of the two towns, Sheffield is by much the more ancient; the command of coal and iron in the same neighbourhood having rendered it, so far back as the thirteenth or fourteenth century, a place for the fabrication of the homely articles used in these days by our ancestors. It is about a century since its razors, knives, and files began to take a more delicate shape. Birmingham, however, embraced a wider range, and advanced with much greater rapidity; but Sheffield also has its adjacent district inhabited by manufacturers, though to a much less extent than the vicinity of Birmingham. This district, called Hallamshire, extends six or seven miles to the W. of Sheffield.

Hardware is made in several other places, such as Bilston, Wolverhampton, Dudley, and Walsall. Each of these towns is situated in Staffordshire, and, in point of manufacture, is small only in comparison with Birmingham or Sheffield. Articles apparently very trifling are manufactured to a surprising extent in different places, such as pins at Gloucester, needles at Red-ditch in Worcestershire, watch movements and main springs at Prescott in Lancashire. The total value of our articles of iron, steel, brass, and copper, including the manufacture from its earliest to its most finished stage, is necessarily fluctuating, but may be computed at L.30,000,000 annually; two-thirds of which appear to be consumed amongst ourselves, whilst the other third is exported to two great markets, the Continent of Europe and the United States of America.

The number of persons employed in the hardware manufacture in England in 1851 was about 465,000. In the United States, iron and coal are found, where land and provisions are certainly much cheaper than in Britain; but the scattered state of American population must, during several ages, oppose serious obstacles to the division of employment necessary in all the nicer branches of the hardware manufacture; particularly as the ease with which the Mississippi and Ohio are navigated by steam opens even the western states to the importation of British goods. Upon the whole, therefore, we look on our hardware manufactures as resting on a solid basis, because in them we combine several advantages;—the raw material, the command of cheap fuel, and the use of machinery, which, the more it is adopted, will bring a greater proportion of the work within the compass of women and boys, and thus lessen the proportion borne by wages in the cost of the finished article.

Linen manufacture.

Linen has never formed one of the staple manufactures of England, flax having been less cultivated amongst us than on the opposite shore of the Netherlands; a country

Statistics.

which, in the fourteenth and fifteenth centuries, supplied the rest of Europe with the finest linens and woollens. When England subsequently advanced in manufacturing arts, the abundant supply of wool pointed out the most suitable branch; and we were contented to continue our imports of linen from the Netherlands, from France, and from Germany, or to favour the manufacture of the sister island in a department which did not excite our jealousy. In Ireland, the linen manufacture dates about two centuries ago, and is said to have owed much of its extension to the measures of the unfortunate Wentworth, in the reign of Charles I. The annual consumption of linen in England a century ago was probably not far below that of her double population at present, owing to the very general substitution in our time of cotton articles. At that time the linen manufacture of England was established chiefly in Lancashire, in Cumberland, and in a county very remote from these, namely, Dorsetshire. In 1745, government, apprised of the extension of the manufacture of coarse linen in Silesia and other parts of Germany, and actuated by the fallacious notion of making a monopoly of all kinds of productive industry, granted a bounty of 1½d. per yard on the exportation of all British linen of a value from 6d. to 18d. per yard; in other words, a premium of 20 or 25 per cent. on the prime cost of all inferior qualities exported. So large a grant soon augmented the manufacture of osnaburgs and other coarse cloths, particularly in Scotland, although the ratio of increase was infinitely smaller than in the case of cotton, where there was no premium, but a rapid improvement of machinery. The demand for bounty in the ten years ending in 1785, was about L.33,000 annually. More recently these impolitic issues were greatly increased; but at length the impolicy of forcing a manufacture in this way having become obvious to every one, the bounties, after being gradually reduced, ceased finally in 1830.

The manufacture is principally carried on in the West Riding of Yorkshire, its chief seat being in Leeds and its neighbourhood, and in Lancashire, Dorset, Durham, and Salop.

Ireland and Scotland, particularly Dundee, are both superior to England in the manufacture of linen. But some of the flax mills established at Hull are on a more extensive scale than any other in the empire. The reader will find under the head of LINEN, in this work, an account of the value of the manufacture in each division of the empire, of the amount of capital, and the number of hands employed in it, &c.

	1851.	1852.
The exports of linen manufactures from Great Britain and Ireland in 1851 and 1852 were of the declared value of	*L.* 3,822,935	*L.* 3,872,491
Thread and small wares	284,461	359,295
Linen yarn	951,426	1,140,565
	5,058,822	5,372,351

Silk manufacture.

In the silk manufacture, as in linen, we have had to contend with a formidable opposition in other countries, particularly in France and Italy; and we have also had to import the whole of the raw material. It would therefore hardly have been attempted by our countrymen, but for the great profits expected from an article of general use amongst the higher classes. Its introduction amongst us goes back to the fifteenth century. About the beginning of the seventeenth it seems to have been carried to a considerable extent, owing certainly not to the luxury of the age, nor to any great proportion of affluent persons in the community, but to silk being almost the only article of apparel in which the vanity of dress could display itself. Towards the end of the reign of Charles II., about the year 1680, raw silk began to be imported in quantities from India; and the English manufacture received a substantial addition by the numbers and ingenuity of the Frenchmen who settled in this country after the revocation of the edict of Nantes in 1683. Various circumstances thus contributed to preserve and extend the manufacture, which continued rather upon the increase till the general substitution of cottons for silks about 1790. This gave a serious shock to the manufacture, from which it recovered only by slow degrees. Its situation had not indeed been at any time prosperous; and the continued complaints of the manufacturers occasioned within these few years a fundamental change in the policy under which it had previously been conducted.

From the first introduction of the manufacture into England down to 1825, foreign silks were either positively or virtually excluded. But the monopoly which was thus secured to the manufacturers produced, what all monopolies invariably do, an indifference to improvement. Instead of trusting to the ingenuity or to the superior skill which they might have called to their aid for preserving their ascendency in the market, the manufacturers depended upon custom-house regulations, and additional penalties on smuggling. In consequence, invention was quite at a stand. Such indeed was the influence of the system in this respect, that in 1826 the member for Coventry (Mr Edward Ellice) affirmed in his place in the House of Commons that the improved silk looms in use in various parts of the Continent enabled the workman to execute *five* times as much work as he could do here; whilst in every business not protected by a monopoly the result was precisely opposite. At length, after a great deal of discussion, it was resolved to adopt a more liberal system. In 1825 a bill was in consequence passed, allowing the importation of foreign silks on payment of an *ad valorem* duty of 30 per cent., accompanied, however, by the effectual reduction of the singularly oppressive duties which had previously been imposed on the imports of raw and thrown silk. This measure, though vehemently opposed at the time, has proved most successful. We are quite sure that we are within the mark when we affirm that the silk trade has made more progress since 1826, when the new system was introduced, than it did during the whole of the preceding century. The following quantities of the raw and thrown silk were imported into the United Kingdom in

Years.	lbs.	Years.	lbs.
1822	2,680,568	1850	5,411,934
1832	4,224,897	1851	5,020,972
1849	5,606,242	1853	7,309,217

This table shows conclusively that the manufacture has increased nearly 200 per cent. since the adoption of those sound and liberal measures which have been the theme of so much ignorant invective. It is of importance, too, to observe, that not only our imports of raw silk, but also our exports of manufactured silk goods, are rapidly increasing. The following table shows this:—

1822	L.381,703	1851	L.1,326,778
1832	529,990	1852	1,551,866
1850	1,225,641	1853	2,044,912

It is plain, therefore, that the manufacture is not increasing merely by reason of an increased demand in the home market, but because we are rapidly gaining on our rivals in the markets of foreign countries. This affords unquestionable evidence of the improvement as well as the extension of the manufacture. In 1852 our exports of wrought silks to France amounted to L.257,555, and to the United States to L.464,590.

Leather manufacture.

Leather, however little it may figure as an article of export, is necessarily one of extensive home consumption in every civilized country, particularly in such a climate as ours, and where there are so many rich and sumptuous equipages. It is matter of regret that we should have so very few *data*, official or otherwise, on which to form an estimate of the export or import of hides in former ages. Such an estimate would possess interest, as indicating the extent of our pasturage and the number of our cattle in comparison with our population. Whatever may have been

Statistics. the case at a remote date, the custom-house returns, for many years past, show, by the annual imports, that the demand for leather has greatly exceeded the home supply of hides. For a long time this importation took place from the Continent of Europe, and from the least civilized quarters; from countries, such as Lithuania and Poland, where the quantity of hides furnished by the cattle materially exceeds that of the leather required by the inhabitants. But since the opening of the trade to South America, it has been found more advantageous to import hides from that continent, where the herds of wild cattle are so numerous as to meet the eye of the traveller in almost every point of the horizon.

On an average there are imported annually about two millions of hides, tanned and untanned. The quantity of leather annually made in England and Wales may be estimated at about 50,000,000 lbs. The largest tanneries are at Bermondsey in Southwark; but there are also very extensive establishments of the kind in the country, as in Cheshire, Lancashire, Westmoreland, Cumberland, and also in Lincolnshire. The late war, by its long continuance, and the magnitude of our army and navy, produced great orders from government for our leather manufacture. Shoes were and still are made wholesale in several towns of Staffordshire, Cheshire, and Northamptonshire; but those made in London, by the principal dealers, are, though expensive, by far the best.

Of the annual value of the leather manufactured into shoes, boots, harness, saddlery, &c., there are no means of forming a correct estimate; but we have merely to consider the population of England, and the unavoidable extent of their wants, to be satisfied that from ten to twelve millions sterling are rather below than above the mark. But whilst our home consumption is so considerable, our export is comparatively small, in ordinary years not exceeding L.800,000; but in 1853 the exports of manufactured leather rose to L.1,578,595. This large increase was probably occasioned by the reckless consignments to Australia. The leather shipped to Ireland is merely tanned; to other countries our exports are in a manufactured shape. The duty on leather was wholly abolished in 1830.

Glove trade. Connected with our general manufacture of leather is the glove trade, a branch of no inconsiderable extent, being carried on in several of the midland and western counties, viz. at Woodstock, Worcester, Ludlow, Hereford, Yeovil in Somersetshire, &c. This branch of industry enjoyed for a lengthened period the protection of monopoly, which, however, was abolished in 1825. Many contradictory statements have been made as to the effects of this measure. We believe, however, that the depression so much complained of has not been produced by it, but by the substitution of cotton gloves for those of leather; and we have no doubt that, had it not been for the greater cheapness and improved quality of leather gloves, caused by the abolition of the monopoly, this substitution would have been carried much farther than it has been. The increased imports of the lamb and kid skins used in the manufacture show conclusively that it is not declining.

Paper. The manufacture of paper, and the trades connected with it, such as printing, bookselling, bookbinding, &c., give occupation to between 60,000 and 70,000 persons. From the excise returns, it appears that the quantity of paper of all kinds manufactured in England in 1852 was 114,521,304 lbs.; and the duty, which is at the rate of 1½d. per lb., plus 5 per cent., amounted to L.751,546. It is difficult to say what portion of this was used in printing books, and how much was consumed by the newspapers; but the quantity used by some of the latter is so great, that a single newspaper, *The Times*, is said to consume about 50 tons a week. See Bookselling and Newspapers.

Brewery. We come next to a branch of industry of a very different description, namely, the brewery. The amount of capital and labour invested in brewing establishments in England is very large, and particularly striking to those who have lived on the Continent, and have contrasted our situation with that of the wine countries of the south of Europe. It is only in Flanders and Germany that breweries are numerous; and in the latter, from the limited capital, and the scattered state of their population, there are hardly any of those large establishments which exist in our metropolis.

An Account of the total number of Quarters of Malt made between the 5th day of January 1852 and the 5th day of January 1853, in the United Kingdom; distinguishing the Quantity made in each Country, and the Quantity used by Brewers, by Victuallers, and by Retail Brewers;—and similar Account for the year ending the 5th day of January 1854.

Quantities of Spirits charged with Excise Duties in the United Kingdom in—

	Gallons.
1850	23,901,432
1851	24,030,933
1852	25,270,262

The quantity of beer brewed in England in 1830 was 4,678,428 barrels. The duty on beer having ceased on the 10th of October 1830, there are no subsequent accounts of the quantities brewed. There can be no doubt, however, from the increased quantity of malt, that the production of beer has likewise greatly increased.

Spirituous liquours. Spirituous liquors form one of the branches of manufacture in which England is dependent on her neighbours, as she imports an annual supply of corn spirit from Scotland and Ireland, rum from the West Indies, and brandy from France. It has been generally supposed that the consumption of gin has increased materially in England since 1825, when the duties were reduced. We are, however, inclined to doubt whether such be really the case, and are disposed to believe that the effect is more apparent than real; in fact, that it has resulted rather from a diminution of smuggling, than from a positive increase of consumption. That such has been the case in Scotland and Ireland is beyond all question; and there seems no reason to conclude that it is otherwise in England. For tables of the quantity of malt used in 1853, and of the quantity of spirits charged with excise duties in 1850, 1851, 1852, see articles Brewing and Distilling.

Lesser manufactures glass, hats, pottery. To the remaining manufactures our limits allow of little space, though several of them would be accounted of great importance in any other country than England. The ex-

Statistics. tent to which such articles as soap and paper are made among us is amply shown by the excise returns; but the list of our exports is of more consequence to the political economist, not from the vulgar notion that it is by export only that national profit is realised, but as indicative of those commodities for which we possess, in our soil, our climate, or our colonial possessions, advantages that give us a superiority over our neighbours. Thus, in the case of glass, the abundance and cheapness of our coal enable us to make an annual export of above L.500,000. In the manufacture of hats, likewise, our command of wool for the coarser kind, and of furs from our North American colonies for beaver hats, enables us to ship to an extent of nearly 45,000 dozen, or L.44,000 a-year. In earthenware we have the advantage of clay, of fuel, and of ready communication by canals. These, joined to the taste and ingenuity of individuals engaged in the manufacture, carried it, in the course of the eighteenth century, to an extent which has rendered it a national object; a tract of seven or eight miles in Staffordshire, called the Pottery District, being almost entirely appropriated to it. The population of this tract is about 60,000. The great outlet is Liverpool, and the shipments take place partly to the United States, partly to the continent of Europe. Exports (comprising procelain) in 1853 reached L.1,337,911 in real value.

The stocking manufacture is carried on chiefly in the counties of Nottingham, Derby, and Leicester. It formerly employed great numbers of women in knitting; but in this, as in most other branches, machinery has greatly superseded manual labour. Lace is made in vast quantities in the midland counties; and here also machinery is extensively applied. And so extraordinary has been the progress of invention in this department, that British lace at present commands a ready sale in all foreign markets, and is largely smuggled even into France.

VIII.—*Commerce and Shipping.*

Commerce. With Ireland the intercourse of England is very great, that country sending us grain, salted and fresh provisions, live cattle, butter, &c. to the amount of six or seven millions annually, and taking largely in return our manufactures, particularly cotton, woollen, and hardware.

North of Europe.—From Russia our chief imports are tallow, hemp, flax, corn, linen, timber, pitch, &c.; from the Swedish dominions, iron and timber; from Poland, wheat, timber, and potash; from Prussia, wheat, timber, and flax. All these countries take our cottons, hardware, and colonial produce.

Central part of Europe.—From Holland our imports are not foreign merchandise, as in the seventeenth century, when the Dutch were the carriers of Europe, but agricultural produce, as oats, wheat, seeds, hemp, cheese, butter; also gin; the whole to a large amount; in return for which the Dutch take our hardware, cottons, and woollens. From France our imports have long been burdened with heavy duties, but still they are large and increasing, consisting chiefly of wine and brandy, silk, lace, gloves, &c. With Germany our chief intercourse is through the medium of Holland and Hamburg. With these countries our exports are large, particularly in cottons, hardware, and colonial produce. Our imports are also very various and large, consisting of wool, corn, flax, timber, linen, and wine, from the vicinity of the Rhine.

South of Europe.—Here we enter on countries of much less industry. From Portugal we take wine in very large, and fruit in smaller quantities, in return for our cottons, our woollens, and our hardware. From Spain we receive wool, wine, brandy, oil, fruits, barilla, &c. Italy, without any commercial treaty, takes a large quantity of our manufactures, and gives in return silk, oil, and fruit. With the Levant, our traffic is similar; consisting of an export of manufactures, particularly printed cottons and hardware, and of an import of silk, fruit, and drugs.

Statistics. The *United States* are, notwithstanding their tariff, our best customers, receiving from us manufactures of almost every kind to a great amount, and sending us in return vast quantities of cotton, tobacco, rice, and flour; but the merchandise received from them being far inferior to the value of our exports, the difference is paid by remittances in money from the Continent of Europe, arising from American merchandise sold there. With South America a wide field of commercial intercourse has been opened; at present, however, the chief articles received from that vast region are bullion, hides, skins, indigo, and cochineal. The trade is, and will long be, subject to the various disadvantages of a newly-settled country, bare of capital, deficient in industry, and possessing but a small number of consumers of European commodities in proportion to its extent and fertility.

From *Asia* we import tea, indigo, cotton, coffee, sugar, piece goods, ivory, drugs, &c. Our principal article of export is cotton goods, for which, how singular soever it may appear, India has, since the opening of the trade in 1814, become one of our very best markets. Besides cotton stuffs and yarn, we send to Asia woollen goods, copper, and a great variety of other articles.

From *Africa* we import drugs, ivory, teak wood, hides, &c. Our exports are but inconsiderable, consisting principally of cotton and linen manufactures. The hopes so frequently entertained, of opening an advantageous trade with the interior of Africa, have hitherto been altogether disappointed, and we do not suppose that they are destined to be more successful in future.

The recent discovery of the gold fields in Australia, and the consequent influx of immigrants into that country, have made it an important market for our produce and manufactures. The declared value of our home produce and manufactures exported to the Australian colonies, including Van Diemen's Land and New Zealand, in 1850, was L.1,574,145, while in 1851, 1852, and 1853 it respectively amounted to L.2,807,356; L.4,222,205; and L.14,506,532. The number of ships that cleared from the United Kingdom for the various Australian colonies was 272 in 1851, 568 in 1852, and 1201 in 1853. A return of the exports and imports to the Australian colonies for 1851, 1852, and 1853, shows some curious results. The exports for 1853 exhibit in some instances an extinction, and in almost every article a decline, except wool, and of course gold, which is not noticed in the return; thus tanner's bark, of which 35,894 cwts. were exported in 1852, was reduced to 4776 cwts. in 1853; and tanned hides, of which 642,198 lbs. were exported in 1852, only amounted to 9842 lbs. in 1853; while untanned hides rose from 30,243 cwts. in 1852, to 41,987 in 1853. Flax and hemp, guano, wine, timber, tortoise shell, whalefins, &c., all declined or disappeared from the return. So did copper and lead ore; but copper partly wrought, that is, in bars, rods, or ingots, increased from 373 tons in 1852, to 686 tons in 1853. Quicksilver fell from 14,631 lbs. in 1852, to 6933 lbs. in 1853; and wool rose from 43,197,301 lbs. in 1852, to 47,075,963 lbs. in 1853.

The amount of exports in 1851 being doubled in 1852, and quintupled in 1853, and probably increased still more in 1854, could not fail to cause a glut in the market, which has produced great embarrassment in the colony, and entailed heavy losses on the speculators.

The value of the produce and manufactures of the United

Statistics.

Kingdom exported from Great Britain and Ireland to foreign parts, according to the real or declared value, amounted in 1832 to.......... .... L.38,251,502

In 1851 they had risen to.......................... 74,448,732

Of which were sent to the United States........................L.14,362,976

To the various British dependencies................ 19,513,960

To Brazil and South American States................ 8,229,628

42,106,564

From which it appears that the United States of America consume nearly one-fifth of our exported produce and manufactures, and that the countries colonized by Great Britain, and those dependent on her, are her customers for nearly a half of all the produce and manufactures which she sells to the world. There is every reason to expect that, under the wise and liberal constitutions granted to the British colonies, increasingly populous and prosperous nations will extend over the present unexplored wildernesses; and as the United States of America are rapidly enlarging their boundaries to the west and the south, and as their increasing population has been uniformly attended with a proportionate increase of trade, it is obvious that the prosperity of Britain is especially bound up with the prosperity of her colonies and with that of the United States. Britain is not less interested in the increasing wealth and prosperity of the other countries of the world; for the richer and more prosperous they are, the better customers will they be for our goods, and the more will they be able to contribute to our comfort and enjoyment by the produce which they will be able to export to our shores.

An Account of the Declared Value of British and Irish Produce and Manufactures Exported from the United Kingdom to various Countries in each Year from 1850 *to* 1852.

Decline in the real value of the exports.

The great increase in the official, and the comparative decline in the real or declared value of the exports, since 1815, has given rise to a great deal of irrelevant discussion. It has been looked upon as a proof that our commerce is daily becoming less prosperous, whereas, in point of fact, a precisely opposite conclusion should be drawn from it. The rates according to which the official values of the exports are determined were fixed as far back as 1696; so that they have long ceased to be of importance as affording any criterion of the actual value, their only use being to show the fluctuations in the *quantities* exported. To remedy this defect, a plan was formed during the early part of Mr Pitt's administration, for keeping an account of the *real* value of the exports, as ascertained by the declarations of the exporters. Those who contend that our trade is getting into a bad condition, argue that the great increase in the official value of the exports since 1815 shows that the *quantity* of the articles exported has been proportionally augmented, whilst the fall in their real value shows that we are selling this larger quantity for a smaller price, a result which, they affirm, is most injurious. But the circumstance of a manufacturer or a merchant selling a large or a small quantity of produce at the same price, affords no criterion by which to judge as to the advantage or disadvantage of the sale; for if, in consequence of improvements in the arts or otherwise, a particular article may now be produced for half the expense that its production cost ten or twenty years ago, it is obvious that double the quantity of it may be afforded at the same price without injury to the producers. Now this is the case with some of the most important articles which are exported from England. Cottons and cotton-twist form a full third or more of our entire exports; and since 1814 there has been an extraordinary fall in the price of these articles, occasioned partly by cotton wool having fallen from about 1s. 6d. per lb. to about 5d. per lb., but more by improvements in the manufacture. Hence, whilst the official value of the exports of cotton goods and twist has increased from about L.18,000,000 in 1814, to about L.100,000,000 in 1853, their declared value has risen only from about L.20,000,000 at the former period to about L.33,000,000 at the latter. Surely, however, this is, if anything can be, a proof of increasing prosperity; it shows that we can now export and sell with a profit (for unless such were the case, does any one imagine the exportation would continue?) nearly four times the quantity of cotton goods and yarn which we exported in 1814 for about the same price. See Cotton Manufacture.

The commercial interests of England long suffered from the inextricable confusion of our maritime laws. From the revolution down to 1786 some hundreds of acts were passed, each enacting some addition, diminution, or change of the duties, drawbacks, bounties, and regulations previously existing in the customs. Mr Pitt has the merit of having first introduced something like order into this chaos. Under his auspices all the separate custom-duties existing in 1787 were repealed, and simple and intelligible ones substituted in their stead.

In the report of the Lords' Committee on Foreign Trade in 1820, it is stated that the laws under which the commerce of the country was regulated amounted to upwards of 2000, of which 1600 were in force in 1815. After this report was printed, Mr Huskeyson introduced great reforms into the laws affecting shipping and navigation. And since his time the repeal of a vast number of custom-duties and the many important and beneficial changes effected by Sir Robert Peel, have vastly simplified our commercial legislation. Various improvements have also been introduced by the late chancellor of the exchequer, Mr Gladstone; and the Customs Consolidation Act of 1853 has brought the various laws relating to the customs into a concise and simple form. It comprises the whole law respecting the importation, exportation, warehousing, smuggling, &c., of goods, with the regulations to be observed in the coasting and colonial trades, &c., and is at once brief, comprehensive, and so clear as to be level to the comprehension of those least acquainted with such matters. Besides condensing and simplifying the various laws respecting the customs, this act has also introduced some most important changes. The merchant is now no longer obliged, when successful in a suit, to pay his own expenses, as was formerly the case; nor are goods in dispute now detained till the point be inquired into and decided, but are given up on the amount claimed being deposited. If the claim is found to have been unjust, the sum overcharged is returned, with interest at the rate of 5 per cent., and the expenses of the suit. The merchant may also, if he consider himself aggrieved by the decision of the board, have the case brought into open court before a commissioner, where he may meet the officer, and learn by examination the real facts of the case. The evidence so taken is reported to the board, who may thereupon confirm or modify their decision; it being optional with the merchant either to abide by it, or to carry the case before a competent tribunal. If the duty or penalty claimed be under L.100, or the case be of a simple kind, it may be tried before magistrates, county courts, or other inferior tribunals.

Shipping.

In order to promote the shipping interest in Britain the navigation laws were passed, which were long considered the safeguards of British commerce. By these laws certain enumerated articles, which in fact comprehended everything that was of importance in commerce, could be brought to our shores only in British ships, or in the ships of the country of which the goods were the produce, or in ships of the country from which the goods were to be brought. Experience proved that these restrictions which were intended for the benefit of British commerce, operated only as fetters upon trade. By the act passed in 1849, the restrictive provisions of the old acts were repealed from and after the 1st of January 1850. Great alarm was created among the shipbuilders and others, by the change, which as they apprehended was fraught with ruin to the trade and commerce of the country; but instead of that, the trade increased more rapidly than before. The amount of tonnage built in 1849 was 121,266, in 1851 it was 149,599, and in 1853 it was 203,171.

The increase has been more remarkable in steam than in sailing vessels: in 1850 the number of steam-vessels built was 36, and their tonnage 3835; in 1853 the number of steam-vessels built was 153, and their tonnage 45,215. Another circumstance which is remarkable, is the recent extraordinary substitution of iron for wood in the construction of steam-vessels. Of the 158 built in 1853, no less than 117 were iron. Dr Strang, in a communication made to the British Association in 1852, states, that during the last seven years there have been constructed, or were constructing, in Glasgow and neighbourhood, 123 vessels, 122 of which were iron. At Greenock and Port-Glasgow, during the same period, there were constructed 66 steam-vessels, 13 of which were of wood and 53 of iron.

The subjoined tables give a complete view of the shipping belonging to the different ports of the British empire, and of the navigation with foreign countries, in 1852 and 1853.

A Return of the Number of Vessels, with their Tonnage (distinguishing Steam from Sailing Vessels), that were Built and Registered in the United Kingdom, distinguishing Timber from Iron Vessels, in the Year 1853.

	Timber.		Iron.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
Sailing Vessels	635	146,380	10	8,576
Steam Vessels	36	3,305	117	44,910
Total	671	149,685	127	53,486

From the statistics of Glasgow, published by Dr Strang in 1855, we learn that the tonnage of steamboats built on the Clyde during thirty years, from 1820 to 1850, amounted to 103,270, while in the three years 1851, 1852, 1853, it amounted to 141,713 in 206 vessels, which were almost entirely of iron. And to show the magnitude of this great department of Scottish industry, he adds that, during a period of twelve months, embracing the greater part of 1853, the tonnage of all vessels built in the ports of the Clyde was 64,114 tons, whereas the total tonnage of vessels built in London in 1853 was only 62,745, and in Liverpool 45,682.

Statistics. *A Return of the Shipping employed in the Trade of the United Kingdom, exhibiting the Number and Tonnage of Vessels that entered Inwards and cleared Outwards (including their repeated Voyages), separating British from Foreign Vessels, also Steam from Sailing Vessels, and distinguishing the Trade with each Country, in the Year* 1853 (*in continuation of Parliamentary Paper No.* 299, *of Session* 1852-3). Statistics.

IX.—*Establishments for Religion and Education.*

Rank of the clergy.

The Church of England has two archbishops and twenty-six bishops, twenty-four of whom are peers of the realm, and all indebted for their appointment to the crown. The province of York comprises six bishoprics, viz. Durham, Carlisle, Chester, Manchester,[1] Ripon, and the Isle of Man; all the rest, to the number of twenty, are in the province of Canterbury. The clerical dignitary next to the bishop is the archdeacon, whose duty, though very different in different dioceses, may be termed that of a representative of the bishop in several of his less important functions. The number of archdeacons in England and Wales, including the Channel Islands, is—in the province of Canterbury 56, in the province of York 15, in all 71. The number of deaneries is 463—in the province of Canterbury 397, and in the province of York 66. The name of Dean (*Decanus*) was probably derived from his originally superintending ten canons or prebendaries. Each bishop has a chapter or council appointed to assist him, and each chapter has a dean as its president; but there are in the Church of England many deaneries of other descriptions. Rector is, in general, the title of a clergyman holding a living of which the tithes are entire; vicar is understood of a living where the great tithes have passed into secular hands. The very general name of curate signifies sometimes (as *curé* in France) a clergyman in possession of a living, but more frequently one exercising the spiritual office in a parish under the rector or vicar. The latter are temporary curates, their appointment being a matter of arrangement with the rector or vicar; the former, being more permanent, are called perpetual curates, and are appointed by the impropriator of the tithe in a parish which has neither rector nor vicar. The name of priest is, in general, confined to the clergy of the Church of Rome; in the Church of England the corresponding term is a clerk in orders. A parson (*persona ecclesiæ*) denotes a clergyman in possession of a parochial church. Deacon is, in England, not a layman, as in Calvinist countries, but a clergyman of limited qualifications, entitled to preach, baptize, marry, and bury, but not to give the sacrament. Readers are not regular clergymen, but laymen of good character, licensed by the bishop to read prayers in churches or chapels where there is no clergyman. (See Adolphus *on the British Empire*, vol. i.)

The division of the country ecclesiastically into *dioceses*, *archdeaconries*, and *deaneries*, took place in very early times. Most of the present bishoprics were founded in the Saxon period: originally there were three archbishoprics—of Canterbury, York, and Caerleon in Wales; the latter was suppressed by Henry I., and the territory annexed to the see of Canterbury. Most of the dioceses, on their first formation, had their limits co-extensive with the boundaries of the kingdoms of the sovereigns who formed them; subdivisions soon, however, were discovered to be necessary; and the Council of Hertford, convened by Archbishop Theodore, decreed that, as the faithful grew to be more numerous, the number of sees should also be increased. The first subdivision was made by this prelate in the diocese of York; and the various princes subsequently made repeated alterations, until at length the whole arrangement settled into its existing shape, excepting the addition made by Henry VIII., and by the recent acts of parliament. Henry, with a portion of the proceeds of the confiscated monasteries, founded seven new bishoprics, viz:—Gloucester, Bristol, Peterborough, Oxford, Westminster, Chester, and Man. The bishopric of Westminster, however, only lasted until 1550, when it was again incorporated with the see of London; and the act of 6th and 7th Will. IV., cap. 77, united into one the sees of Gloucester and Bristol, and created two additional—Manchester and Ripon. By this statute, the Ecclesiastical Commissioners were authorized to alter the limits of nearly all the rest, by effecting a transference of parishes from one to another, with a view to the more convenient distribution of territory and population.

Archdeacons anciently were only members of chapters without territorial jurisdiction. The assignment of specific limits for archdeaconries took place soon after the Conquest.[2] The act of 6th and 7th Will. IV., cap. 77, gives power to the ecclesiastical commissioners to re-arrange the boundaries of the ancient, and to form certain new, archdeaconries. The new ones formed in exercise of this authority are Bristol, Maidstone, Monmouth, Westmoreland, Manchester, Lancaster, and Craven.

Deans are principally of two kinds: (1) those attached to cathedrals, who are the heads of the different chapters; and (2) rural deans, who perform certain functions as assistants to the bishops, in particular definite portions of the several dioceses. These *Rural Deaneries* were recognised ecclesiastical divisions of a diocese in Saxon times. They seem to have been designed to correspond with *hundreds* in the political division of the country, as archdeaconries were possibly intended to correspond with counties. The etymology of the word (*Decanus*) favours this idea; and it is not improbable that all such deaneries originally embraced districts with *ten* churches, and no more; their boundaries, once settled, never having been disturbed, although increase of population caused an increase in the number of religious edifices. Some of them still contain ten churches only. These deaneries gradually fell into disuse from the period of the Conquest; but recent legislation tends to their revival.

The clergy are in theory supposed to assemble in convocation during the sitting of parliament to consult on ecclesiastical subjects. The convocation is summoned by writ from the crown directed to each archbishop, but it cannot constitute any canons without license from the crown: consequently the assembly since the time of Henry VIII. has been a mere form; no business is transacted. Lately, however, attempts have been made to revive this obsolete court, and on the last meeting (1854) the assembly sat a short time during the day, and entered on some formal proceedings.

A clerical education in England is much less extensive than in Calvinist countries; in Scotland, Holland, Switzerland, or the north of Germany, after going through a course of classics and philosophy, a second course is required for theology solely; but in England the former is sufficient. The degree of bachelor of arts requires an examination and a university residence of three or four years; but to qualify for the acceptance of a curacy, a certificate of attending a single course of lectures in divinity is all that is necessary.

Livings.

The total number of benefices in England and Wales is 11,728, of which 9669 are in the province of Canterbury and 2059 in the province of York. From this multiplicity of benefices, and from the general smallness of the incomes, have arisen two great irregularities, pluralities and non-residence, both forbidden by the ancient statutes of the church, but both long sanctioned by usage. Many clergymen hold livings without doing duty at any of them; others do duty in one or in two which are adjacent to each other, and have a curate for the more distant; whilst curates frequently do duty at two and sometimes at three distinct places of worship. To prevent, or at least to lessen, the abuse of non-residence, an act of parliament was passed in 1813, directing that every non-resident incumbent should nominate a curate at a salary of not less than L.80 a-year, unless the

---

[1] By the act 10th and 11th Vict., cap. 108, a new bishop (of Manchester) was created, but the act declares that the number of lords spiritual sitting in parliament shall not be increased by this creation. The bishop of Sodor and Man, who was formerly appointed by the Duke of Athole, is now appointed by the crown; he has no seat in the House of Lords, and his salary is only L.2000. The bishops of London, Durham, and Winchester, rank immediately after the archbishops; the others according to priority of consecration; and the last appointed bishop has no seat in the House of Lords.

[2] The first assignment was by Archbishop Lanfranc, A.D. 1165.

Statistics.

entire living should be less. The effect of this act was to reduce the number of non-resident clergymen by 800 fully; they had previously been about 4700; but in 1815 the official return to parliament of the incumbents in England and Wales was as follows:

Non-resident from the following causes:

Sinecures	52
Vacancies	164
Sequestrations	40
Recent Institutions	87
Dilapidated churches	32
Held by bishops	22
Law-suits, absence on the Continent, &c.	122
Livings from which no report	279
	798
Incumbents non-resident from other causes	3,856
Incumbents resident	5,847
	10,501

Returns for the year 1850, made by the respective archbishops and bishops in England and Wales, give—

The total number of benefices in which the incumbents were resident	8,077
Ditto, ditto non-resident	2,952
Miscellaneous cases	699
Total	11,728
The number of benefices on which there was a glebe-house was	8,214

Of these 11 are under the annual value of L.10; 19 from L.10 to L.20; 32 from L.20 to L.30; 235 from L.30 to L.50; 1629 from L.50 to L.100; 1602 from L.100 to L.150; 1354 from L.150 to L.200; 1979 from L.200 to L.300; 1326 from L.300 to L.400; 830 from L.400 to L.500; 954 from L.500 to L.750; 323 from L.750 to L.1000; 134 from L.1000 to L.1500; 32 from L.1500 to L.2000; 16 of L.2000 and upwards. Among the last are the rectory of Stanhope in Northumberland, and that of Doddington in Cambridgeshire, the former being of the annual value of L.4863, and the latter of L.7306.

Churches.

The income of the Church of England is derived from lands, tithes, church-rates, pew-rents, Easter offerings, and surplice fees. The distribution of these revenues, according to the report of the commissioners for inquiring into ecclesiastical revenues, was, in 1831, as follows:—

Bishops	L.181,631
Deans and Chapters	360,095
Parochial Clergy	3,251,159
Church-rates	500,000
	L.4,292,885

The total number of churches and chapels of the Church of England was then 11,825; and from that time to 1851, 2029 new churches had been built. The value of church property had also much increased, so that the total income of the church in 1851 was estimated to be considerably above L.5,000,000. The number of beneficed clergy in 1831 was 10,718, and consequently the gross average income of each would be about L.300 a-year; the number of curates was 5230, whose stipends amounted in all to L.424,695, averaging L.81 per annum to each. As many incumbents possessed more than L.300 a-year, and some curates more than L.81, the remuneration of others was below these sums respectively. For the purpose of raising the incomes of incumbents of the smaller livings, the governors of "Queen Anne's Bounty" annually receive the sum of L.14,000, the produce of first-fruits and tenths, which were formerly paid to the Pope, but were at the Reformation appropriated to the sovereign, and by Queen Anne granted "for the augmentation of the maintenance of the poor clergy." The ecclesiastical commissioners also apply to the same object a portion of the surplus proceeds of episcopal and capitular estates.

Statistics. Tithes.

Tithes necessarily fluctuated with the state of agriculture, and, during the distress of 1815, the deficiency in this respect became alarming. Application was made to parliament, and the subject was for some time under serious discussion; but the rise of corn in 1816 and 1817 prevented any other measure than an act founded on a committee report of 18th June 1816, authorizing the possessors of tithes, laymen as well as clergymen, to grant leases of them for a term not exceeding fourteen years.

By Act 6th and 7th Will. IV., cap. 71, a board of commissioners called the "Tithe Commissioners for England and Wales" was appointed, the object of which was to convert the tithes into a rent-charge, payable in money, but varying in amount according to the average price of corn for seven preceding years. The amount of the tithes was to be calculated on an average of the seven years preceding Christmas 1835; and the quantity of grain thus ascertained was to remain for ever as the annual charge upon the parish; and the annual money value was ascertained from the returns of the comptroller of corn, who publishes annually in January the average price of an imperial bushel of wheat, barley, and oats, computed from the weekly averages of the corn returns during the seven preceding years. The commissioners report in 1851, that voluntary commutations had been commenced in 9634 tithe districts; 7070 agreements had been received, of which 6778 had been confirmed; and 5529 drafts of compulsory awards had been received, of which 5260 had been confirmed. Thus in 12,038 tithe districts the rent charges had been finally established by confirmed agreements or confirmed awards.

Clerical terms.

A prebend is a provision in land or money given to a church *in præbendum*, that is, for the support of a clergyman whose title may be either prebendary or canon. Advowson (*advocatio*) is the right of presentation to a living, and was first vested in those laymen who were founders of or benefactors to livings. A living is held *in commendam* when, to prevent its becoming void, it is committed (*commendatur*) until it can be conveniently provided with a pastor. The *modus* (*modus decimandi*) is a composition for tithes; it may be either perpetual or during the lives of the contracting parties. The lay impropriators of tithe, so frequent in England, date from the dissolution of the monasteries in the reign of Henry VIII.; patrons were then allowed to retain the tithes and glebe in their own hands, without appointing a clergyman; in cases of such appointment, the clergyman was called *vicarius*, or representative of the patron.

By the census of 1851, the clergymen in Great Britain of the Established churches amount to 18,587—17,320 in England and Wales, 143 in the Islands of the British Seas, and 1124 in Scotland; the other Protestant ministers to 8521; the Roman Catholic priests to 1093; theological students, and various real or pretended religious teachers, to 1477. The total number in the class is 30,047. The churches have connected with them a considerable number of subordinate officers, whose time is, however, only very partially engaged; so that they have generally other occupations under which they are returned. Thus only 2386 men are referred to the head "parish clerks;" 815 are called sextons, 756 church officers; and the whole *sub-class* comprehends 4573 males, 901 females.

The Dissenters in England are, first, the Presbyterians, who nearly coincide with the Church of England as to doctrine, but differ in church-government, allowing no hierarchy in individuals; next the Independents, who go further, and disclaim hierarchy in synods and other collective assemblies; thirdly, the well-known sect of Quakers, who date from the middle of the seventeenth century; and, lastly, the more numerous Methodists, who date from 1729. Of the Baptists, the chief characteristic is their not receiving baptism till they become adults. The Catholics in England are not numerous, but comprise a large proportion of wealthy families.

Education.

In regard to the mode of education in England, there is much both to commend and to censure. Scotland has for a century past been in possession of a larger proportion of parish schools; but the utility of these is much lessened by an established routine of teaching Latin to almost all youths, whatever be their intended line of life. In England this absurdity is less prevalent, because most of the schools are private undertakings, the managers of which are necessarily guided by considerations of utility. The youth destined for a life of business are thus saved a serious waste of time; their education, if imperfect, is not supererogatory; but, on examining the higher seminaries of England, we find much ground for disappointment, and many marks of a blind adherence to ancient usage. The universities of Oxford and Cambridge are evidently inadequate for the education of the nobility, the gentry, and the clergy of so populous a country. Their course of study, also, is quite unsuitable to the future occupations of many of the students. They were originally designed for the education of churchmen; and, to this day, Latin, Greek, and mathematics, form the chief objects of instruction. In 1850 a parliamentary commission was appointed to inquire into the state, discipline, studies, and revenues of the universities of Oxford and Cambridge; and in the session of 1854 a bill was passed by which various important reforms were introduced into the management and government of these valuable institutions.

Statistics.

Education of the poor

No country rivals England in the magnificence of her academical buildings. Whilst in France, Germany, or Holland, a university possesses only a single pile of building, Oxford and Cambridge can boast for every college a large, commodious, and generally an elegant structure. The endowments appropriated to them are very various, both in their origin and destination, but these arise chiefly from land, and, having increased with the rise of rents, are in many cases very ample. The destination of these funds is regulated by the bequest of the donors and the established usage of the colleges; part going to the students under the name of exhibitions or scholarships; part to the head and fellows; and a further part consisting in livings, which devolve on the fellows, and lead to their removal from the university. A hall is an inferior college; an academical establishment not incorporated or endowed, but possessed of exhibitions or other provisions for students. Oxford has nineteen colleges and five halls; Cambridge has twelve colleges and four halls.

Two institutions, the London University and King's College, have recently been founded in the metropolis, with the view of obviating the defects complained of at Oxford and Cambridge, and of cheapening and diffusing the advantages of an academical education.

Boys in England are taught the classics, either in the lesser schools established at every town of consequence throughout the kingdom, or at the great public schools. Of the latter, the principal are Eton, Westminster, Winchester, and Harrow; also the Charter-house, St Paul's, and Merchant Tailors' School. These seminaries, at present so expensive, and attended by youths of the first family, had their origin in a fund or provision set apart for scholars of humbler birth. This has served as the basis of a stately superstructure, each school having attracted, by the advantage of situation or the repute of the teachers, a much greater number of pupils in independent circumstances. But in each a proportion of the scholars are still on the foundation. At Eton there are seventy thus provided for; and the same number at Winchester.[1] This subject will be resumed and treated in detail under the article UNIVERSITIES.

There are 304 collegiate and grammar schools supported by endowments the annual revenue of which is L.128,693; and there are 1607 other schools possessing endowments which amount to L.160,293. This, however, gives a very inadequate idea of the annual value of the endowments which have been from time to time left for the purpose of education. Lord Brougham estimated the annual amount at L.500,000, and recent writers consider that the estimate is not too high. A board was appointed by parliament to investigate the misappropriation of these funds, but the powers of the commissioners are either too limited, or they seem to be unwilling to exercise them with sufficient vigour to make the funds available.

[1] *Reports of the Education Committee*, 1817 and 1818.

Statistics.

Popular education in England is almost entirely the creation of the present century. Before 1801, the total number of public and private schools was only 3363; in 1851 they were 44,836. In 1781, Mr Raikes of Gloucester with difficulty collected the first Sunday school; in 1851 they numbered 23,137. In 1818 the scholars attending the day schools were 674,883; in 1851 they were 2,144,378. The Sunday scholars in 1818 were 477,225; in 1851 they 2,407,642. The records of the condition of society a century or even half a century ago describe a state of ignorance and immorality both gross and general. The happy transformation which has since taken place is attributable in no small degree to the great extension of education. Nevertheless the state of education is much below what it ought to be, both in quantity and quality.

It is generally assumed that one-eighth of the whole population would be a satisfactory proportion for attendance at the day schools, after making due allowance for practical impediments. This proportion of the population of England and Wales (17,927,609) gives 2,240,951 as the number that should have been under school instruction in 1851. But Mr Horace Mann, in his report to the Registrar-General, assuming that the school instruction of a child should not be procrastinated after five years of age, and should not be relinquished earlier than twelve (the legal period in Prussia is from five to fourteen), calculates, after making every deduction for ill health, employment, receiving education at home, &c., that there should be 3,015,405 children attending day schools. According to this estimate, as the total number of children attending school according to the census of 1851 was 2,144,378, there must have been 871,027 receiving either a mere fraction of education or none at all.

The following classification of the 29,425 private schools in England will give some idea of the quality of the education:—

1. Superior—Classical, Boarding, Proprietary, Ladies, &c.	4,956
2. Middling—Commercial, &c.—teaching, Arithmetic, English Grammar, and Geography	7,095
3. Inferior—Principally dame schools, only Reading and Writing taught, the latter not always	13,879
Underscribed	3,495
	29,425

In the case of 708 out of these 13,879 the returns were respectively signed by the master or mistress with a *mark*. The same is noticeable with respect to 35 *public* schools, most of which had small endowments.

The following table will show that not only has popular education in this country been promoted mainly by a religious influence, but that it is now becoming rapidly a matter of denominational activity. This tendency, so far as the Dissenters are concerned, has only recently been evidenced; for schools upon the British system (which discourages sectarian teaching) satisfied their wants till about ten years ago. The controversies of that period, however, when it seemed to the Dissenters that the government designed to place too much of the education of the poor in the hands of the Established Church, produced very great exertions on the part of the various bodies to counteract this supposed design.

Up to 1853 all that had been accomplished for national education was the fruit of private liberality acting principally through the *British* and the *National* educational societies, but in 1833 government first proffered its assistance by voting an annual grant of L.20,000, which was continued till 1839, when it was raised to L.30,000. In 1842–3–4 it was L.40,000; in 1845, L.75,000; in 1846–7, L.100,000; in 1848–49–50, L.150,000; and in 1853, L.260,000.

None of this money was given towards the expense of maintaining schools, but only towards the cost of buildings, the purchase of school apparatus, or in aid of the salaries of efficient teachers. But certain sections of the Dissenters, who object to the interference of the state either in the church or the school, felt themselves precluded by the principles they had adopted from accepting any aid from the government grants, and therefore depend entirely upon voluntary liberality for the maintenance of their schools.

X.—*Establishments for purposes of Charity—Poor Rates.*

The public charities of England are very numerous; the bequests of benevolent founders in this country exceeding those of the zealous Catholics of France or Spain, as well as those of the once affluent Protestants of Holland. Our limits do not admit of a notice of the great variety of charitable institutions which abound in the country. In the metropolis alone there were, in 1853, 530 charitable institutions, which disbursed during the year the aggregate amount of L.1,805,635. Among these, grammar-schools and educational establishments, such as Merchant Tailors' and St Paul's, are not included, nor miscellaneous endowments in the gift of city corporations and parishes.

Amongst the principal *Hospitals* are—Bethlem Hospital; St Luke's, Old Street; St Bartholomew's, West Smithfield; Guy's, in Southwark; the Lock Hospital, Hyde Park Corner; the London Hospital, Whitechapel Road; the Magdalen Hospital, St George's Road; the Middlesex Hospital, Berner's Street; St Thomas's; the Foundling Hospital.

A *College*, in the sense of a charity, is an alms-house on an enlarged scale, under the direction of a master and other incorporate officers. There are only three in the neighbourhood of London, namely, Bromley, Morden, and Dulwich Colleges.

Alms-Houses.—These are very numerous, viz., the Haberdashers', Mercers', Skinners', E. India Company's, &c.

School Charities.—These institutions are also very numerous. Amongst the most remarkable are—Christ's Hospital, or the Blue Coat School; Marine Society; School for the Indigent Blind; &c.

Poor-rates. A compulsory provision for the support of the poor has existed in England for a lengthened period. Its introduction dates from the reign of Henry VIII., and it was perfected in that of Elizabeth; the famous statute of the 43d Eliz., cap. 2, having embodied all the principles, with many of the regulations, still to be found in the system. The law has, however, been repeatedly modified, and very great alterations have taken place in its administration. These changes will be fully detailed in our article on the POOR-LAWS; and in it also the reader will find an examination of the important and difficult question as to the policy of a compulsory provision for the support of the unemployed poor. Here we have only to state what has been the amount of the rates levied on account of the poor, from what sources they have been derived, and how they have been distributed.

Paupers. *Paupers.*—According to the returns of the poor-law board, the number of paupers in receipt of relief both in-door and out-door in England and Wales was 862,827 on 1st January 1851, and 813,089 on 1st July 1851. At the time of the census 126,488 paupers were inmates of workhouses in England and Wales, being in the proportion of one in-door pauper to every 142 inhabitants, or 7 in every 1000. Out-door paupers are often in receipt of relief for very short periods on account of sickness or temporary distress; but those received into the workhouses are for the most part supported for long periods—frequently for the remainder of their days.

In Scotland the number of poor on the relief register on 14th May 1851 was 76,906. At the census there were 5438 in-door paupers, chiefly in the southern Scottish counties, where poor-houses have been established by means of funds raised by rate in many parishes; while in the northern counties the progress of the new system of legal assessment has been but partial.

Years ended at Lady-day.	Total Expenditure for the Relief of the Poor in England and Wales.	Rate per Head on Population.	
	L.	s.	d.
1845	5,039,703	6	0¾
1846	4,954,204	5	10½
1847	5,298,787	6	2½
1848	6,180,764	7	1¾
1849	5,792,963	6	6½
1850	5,395,022	6	1
1851	4,962,704	5	6½
1851 (In Scotland)	535,944	3	8¾

The relative numbers of the *sexes* of in-door paupers do not, on the whole, differ greatly. In England, 64,294 are males, and 62,194 females; in Scotland, the females are most numerous, being 3239 to 2199 males. To every 10,000 males and females respectively living in Great Britain there are 65 males and 61 females in workhouses.

The following statements rest mainly upon the authority of the masters of workhouses. Almost every branch of employment—professional, commercial, agricultural, manufacturing—is represented, and the returns include some large numbers of particular classes. Of agricultural and other labourers there are 17,700, of whom 8113 appear at the ages above 60; domestic servants 15,036, all but 679 of whom are females, and a large proportion in advanced life—a fact which points significantly to the want of a suitable provision for this class when worn out or otherwise incapacitated for service; charwomen, 2001; washerwomen, 1799; milliners and dressmakers, 2464; shoemakers, 1901; tailors, 1022. A large number, 70,943—of whom 50,197 are under 15 years of age—are returned without any specific statement as to their occupations. In the workhouses are found some of the oldest people in the country; 18,489 in-door paupers are upwards of seventy years of age, including 360 aged ninety and upwards.

Besides the poor-rates the total county rate expenditure of England in the year ending Michaelmas 1850 was in round numbers L.1,400,000; of this sum L.257,000 was defrayed by allowances from the Treasury in aid of the expenses of prosecutions and prisoners, and L.138,000 was paid out of the parish poor-rates for the maintenance of lunatics in county asylums. The sum actually raised as county rate from the rate-payers, amounted only to L.796,000; and as this sum was levied upon an assessment of L.64,598,831, the average poundage of the county rate throughout England, which measures the real pressure upon the rate-payer, was less than 3d. in the pound.

Prisoners. *Prisoners.*—The statistics of crime in Great Britain presented in the criminal returns prepared at the home office furnish a digest of the nature of the offences, the number of offenders, and the result of the proceedings in each year. At the census, information was obtained which enables us to state the numbers confined on a particular day, with their ages and occupations—points of much interest, as supplemental to those embraced in Mr Redgrave's tables.

The total number of persons in the different prisons, bridewells, convict-depôts, and hulks in Great Britain on the 31st March 1851, was 26,855; 22,451 males, and 4404 females. Of these some were debtors, others were untried; but the majority were convicted and undergoing sentence. The proportion of prisoners is, therefore, 1 in 785 of the general population. Owing partly to the government convict establishments and the hulks, the proportion is higher in England than in Scotland; and in London, Hampshire, and other localities, it, for the same reason, exceeds the average of England.

To every 100,000 males and as many females in Great Britain, there are respectively 220 males, and 40 females confined in prisons. In London the proportions are as high as 450 males and 90 females; while in the Welsh division they are only 68 males and 17 females in 100,000.

According to the criminal returns, the number of persons committed in Great Britain in 1851 was 31,961—25,283 males, and 6678 females. In Scotland the committals of females are proportionately more numerous than in England.

With respect to the *ages* of prisoners, it appears that 6833, or 25 per cent. of the whole number, are under twenty years of age, while 134 are aged seventy and upwards. The returns of *occupations* present a great variety of items, and will doubtless be examined with attention by all interested in the various questions affecting the criminal class which have proved so difficult of solution both to the statesman and the philanthropist. Amongst the employments furnishing the largest numbers are—agricultural labourers, 3026; labourers not particularly described, 5062; domestic servants, 1174, of whom 220 are males and 954 females; shoemakers, 891; tailors, 533; hawkers and itinerant venders, 614; engaged in the cotton manufacture, 694; carpenters, bricklayers, masons, slaters, plasterers, and plumbers, together, 1381. The occupations of 24,189 prisoners are described; the residue, we presume, represents the incarcerated class of *professional* criminals.

Lunatics. *Inmates of Lunatic Asylums.*—The public and private

Statistics.

establishments for the insane are subject to definite regulations, enforced by the inspection and control of the proper authorities; the number of patients is restricted within the limits of the accommodation afforded, and every private asylum is duly licensed. The physiology of mental disease has likewise engaged the attention of eminent medical men, and generally a gentle and humane treatment has been successfully adopted, in the place of harshness and unnecessary restraint.

At the period of the census there were in the various lunatic asylums, and other institutions for the reception of the insane in Great Britain, 18,803 persons; 8999 males, and 9804 females. Lunatic paupers in the insane wards of workhouses are not included, as they are not usually distinguished from other paupers in the returns. By the establishment of county lunatic asylums, however, the number of insane and fatuous paupers in workhouses has been greatly reduced.

The proportion which the lunatics in asylums bear to the general population is 1 in every 1115 inhabitants in Great Britain. To every 100,000 males and 100,000 females living, there were 88 males and 91 females in these institutions.

The former occupations of lunatics will be examined with interest. It will be seen that the educated and professional classes furnish many cases of insanity: of clergymen and ministers, 84 are returned; barristers and solicitors, 88; physicians and surgeons, 108; officers of the army and navy, 95; the East India service, 118; schoolmasters and teachers, 258. Amongst the largest items are—labourers, 1794; female domestic servants, 1753; shoemakers, 364; weavers, 240; and tailors, 224. No information is given as to the employments, if any, of 7674 lunatics of all ages.

Patients in hospitals.

Patients in Hospitals for the Sick.—Although of late years additional hospital accommodation has been provided in towns, it may be doubted whether the habits and feelings of the people of this country render necessary an extended provision, independent of the poor-law system, for the reception and care of the sick. In the principal cities and towns, hospitals and infirmaries, supported chiefly by the voluntary subscriptions of the benevolent, are established with great advantage to the working classes; and in many market-towns and large country parishes, for want of these institutions for their reception, persons of the same rank in life, when suffering from malignant fevers and other contagious diseases, often remain in small dwellings or single chambers, where the healthy and the sick are crowded together, aiding the progress of infection, until the disease spreads itself on every side. Still, the removal of the sick to infirmaries is not unattended with disadvantages; and the strong inclination on the part of their relatives to keep them at home, where they can be watched and attended by those connected with them by family ties, is both natural and commendable. To domestic servants and persons living away from their relations, or having no homes to resort to in sickness, these institutions are of great benefit.

The census returns show only 9876 persons of both sexes—5525 males, and 4351 females—in general hospitals for the sick on the night of 30th March 1851. Patients in the military hospitals are not included. More than one-third of the whole number of the patients is returned in the various hospitals in London, where the sick are driven by their wants, or attracted by the extent of accommodation, the high professional standing of the medical officers, and the immediate attention that is given in cases of accident and emergency.

In Great Britain 1 in every 2122 of the whole population is sick in a general hospital; and of 100,000 males and as many females living, there are respectively 54 male and 41 female patients.

Amongst the occupations furnishing the largest number of patients are the following:—domestic servants, 1797, of whom 157 are males and 1640 females; agricultural and other labourers, 1495; seamen, 197; milliners and seamstresses, 262; charwomen and washerwomen, 166; shoemakers, 173; carpenters, 123.

The following table shows the proportion which the inmates of the public institutions adverted to bear to the male and female population:—

Proportion of Paupers in Workhouses, Prisoners, Lunatics in Asylums, and Patients in Hospitals, to the Male and Female Population in Great Britain, 1851.

	To every 10,000 living, the Proportion of

The blind.

The Blind.—In Great Britain and the Islands of the British Seas there are 21,487 persons—11,273 males and 10,214 females—returned as totally blind. The number in England and Wales is 18,306 of both sexes; in Scotland, 3010; and in the Islands of the British Seas, 171 persons. These numbers furnish a proportion relatively to the whole population of 1 blind in every 975 persons in Great Britain—1 in every 979 in England and Wales, 1 in 960 in Scotland, and 1 in 837 in the Channel Islands and the Isle of Man.

These results admit of favourable comparison with the relative numbers in Ireland, which, according to the census, are 1 in every 864 inhabitants. In the level portions of Europe, comprising Belgium, Hanover, parts of Germany, and the plains of Lombardy and Denmark, the proportion is stated to be 1 blind in every 950 inhabitants—but slightly differing from the average of Great Britain. In more elevated regions the proportion is considerably lower; but in Norway it is found to be 1 in every 482 inhabitants.

Payment of wages out of poor-rates.

It is obvious, from the preceding tables, that, allowing for the increase of population, the increase of the rates has not been nearly so great as is commonly supposed. The pernicious practice of ekeing out wages by means of contributions from the rates began in 1795; and formed one of the principal evils in the state of the English poor.

"The price of corn, which, at a medium of the three years ending with 1794, averaged 48s. 2d., rose in 1795 to 75s. 2d. As wages continued stationary at their former elevation, the distress of the poor was very great; and many able-bodied labourers, who had rarely before applied for parish assistance, became claimants for relief. Instead of meeting this emergency, as it ought to have been met, by temporary expedients, and by grants of relief proportioned to the exigency of every given case, one uniform system was adopted. The magistrates of Berks, and some other southern counties, issued tables, showing the wages which, as they affirmed, every labouring man should receive, according to the number of his family, and the price of bread; and they accompanied these tables with an order, directing the parish officers to make up the deficit to the labourer, in the event of his wages falling short of the tabular allowance! As might have been expected, this practice did not cease with the temporary circumstances which gave it birth, but continued to be acted upon down to the passing of the Poor

Statistics.

Law Amendment Act. It was in fact very generally established in the southern half of England, in large districts of which there were no longer any independent labourers to be found; and produced an extent of artificial pauperism and moral degradation that could hardly have been conceived possible. (M'Culloch's *Principles of Political Economy*, 4th edit. p. 463.)

XI. *Crimes in England and Wales.*

The criminal tables for the year 1853 complete a series of twenty years, compiled from the same authentic materials and upon precisely the same principles. They form an accurate comparison of the state of the commitments for trial during that period; the only disturbing causes being some changes in the laws constituting crimes and fixing punishments.

These totals, comparing the first year with the last, show an increase of 20·5 per cent., while the increase of the population in the same period is 27 per cent.; comparing the total of the last ten years with the total of the first ten years, the increase amounts to 8 per cent. only. In each of the last three years the commitments have slightly decreased, and since 1842 the tendency to decrease has been almost uninterrupted.

In the last year the decrease of the commitments was 1·8 per cent. only; but it extended over twenty-eight English counties, including all the agricultural districts. It seems unnecessary to enumerate the details of this trifling decrease. They show little variation which calls for particular remark; but it may be observed generally, that the decrease extends to all the violent offences, both those against the person and those against property.

TABLE, *Showing the number of Persons committed for Trial or Bailed in each of the last Ten Years.*

OFFENCES.	1844.	1845.	1846.	1847.	1848.	Total of Five Years, 1844-48.	1849.	1850.	1851.	1852.	1853.	Total of Five Years, 1849-53.

On the 1st September 1853, an act came into force (16th and 17th Vict., cap. 99), substituting for transportation a sentence of "penal servitude" in the United Kingdom, in all cases where a sentence of transportation for a term of less than fourteen years might have been passed; and, at the discretion of the court, when the offence warrants a longer term of transportation.

The sentences passed in 1853, are given in greater detail in the following table, and are compared with those in the nine preceding years:—

	1844.	1845.	1846.	1847.	1848.	1849.	1850.	1851.	1852.	1853.

XII. *Establishments for the purposes of War and Defence.*

These consist, of course, principally of the army and navy. But as detailed accounts, derived from the very best sources, are given, under the articles ARMY and NAVY in this work, of all the most important particulars relating to the history and present state of each of these grand departments of the public force, it would be quite superfluous to enter into any details with respect to them in this place.

Complete returns of the men engaged in the defence of the country were furnished by the war departments, the admiralty, the ordnance, and the offices for half-pay and pensions, to the census commissioners; from which it appears that the army and navy had on 31st March 1851—exclusive of the East India Company's army and navy, and officers of the staff of the army, not serving with their regiments and militia—178,773 effective men; namely, 142,870 in the army, 35,903 in the navy; besides 83,797 non-effectives on half-pay or pensions—63,305 from the army, 20,492 from the navy. The *effectives* of the *army* comprised 6593 officers, 136,277 men; and the 142,870 were composed of—cavalry, 12,911; infantry, 115,567; artillery, 12,006; engineers, 2386: of whom were stationed in England and Wales, 36,504; Scotland 2655; the Islands in the British seas, 993; Ireland, 26,272; the Colonies, 44,402; India, 29,096; on passage out or home, 2948.

Ireland, comprising so much of the Celtic, and Scotland, so much of the Celtic and Scandinavian populations, con-

tribute largely to the army. England, with its Anglo-Saxon and Scandinavian people, whose "home is on the deep," furnishes seamen to the navy.

Birthplace of Soldiers and Seamen.

	England and Wales.	Scotland.	Ireland.	Islands in the British Seas, and Abroad.

Navy, exclusive of Marines (all ranks)......	20,125	1,078	2,532	1,168
	Proportion in 100.			
Army (all ranks)	47	11	37	5
Navy, exclusive of Marines (all ranks)......	82	4	10	4

In the middle of 1851 there were 5,610,777 men of the age of twenty and upwards of *Great Britain;* of whom 183,255 belonged to the army and navy—120,407 as effective force, and 62,848 on half-pay, or as pensioners liable to serve under certain contingencies. The active force is 2 per cent. of the men of great Britain, or 1 in 47; and if 13,673 men and boys under the age of twenty are added, making 134,080, 1 in 158 of the *total population* of Great Britain is found to be engaged in the army and navy.

One-fourth part of the active force of the *United Kingdom*, employed in Ireland, is left out of the calculation; as well as the East India Company's army and navy.

Exclusively of the army and navy, great numbers of individuals in all parts of the country are enrolled as special constables, who may be called upon by the magistrates and other civil authorities to assist in suppressing disorders and in preserving the public peace. In London, and in other great towns, strong bodies of police are also employed, constituting a sort of half military half civil force.

XIII.—*Revenue and Expenditure.*

The various taxes, the produce of which forms the public revenue of the kingdom, will be described in the article TAXATION in this work, where also their real incidence and practical operation will be pointed out. The subjoined table gives an account of the income and expenditure of the empire for the year ending 5th January 1854.

An Account of the Net Public Income of the United Kingdom of Great Britain and Ireland, in the Year ended the 5th day of January 1854 *(after abating the Expenditure thereout defrayed by the several Revenue Departments), and of the Actual Issues or Payments within the same Period, exclusive of the Sums applied to the Redemption of Funded or paying off Unfunded Debt, and of the Advances and Repayments for Local Works, &c.*

XIV.—*National Debt.*

The national debt consists, as every one knows, of sums borrowed to make up deficiencies of revenue. It originated during the wars carried on by William III. against France. Its contraction was then not a matter of choice, but of necessity; for, owing to the numerous adherents the exiled family of Stuart had in the country, it would have been impossible to have imposed such an amount of taxes as would have sufficed to defray the expenses of the war, without inflaming the popular discontent to such a degree as would most probably have been subversive of the new government.

Statistics.

At first it was usual to fund the amount of stock equal to the sums borrowed; but since the reign of George II. a different practice has obtained; and it has been judged advisable to fund generally in a stock bearing a low rate of interest, by proportionally increasing its amount. Thus, suppose interest were five per cent., and that government wished to borrow in three per cent. stock; in such a case they would give L.166⅔ of stock for every L.100 money paid into the exchequer. By affording, in consequence of the increase of the stock, greater scope for speculation, this practice is supposed to have enabled government to borrow on rather lower terms at the time; but, by disabling them from reducing the interest on such loans at the close of a war, when the market rate of interest uniformly falls, it has proved most signally injurious. It is not going too far to say that this blunder costs the public at this moment L.7,000,000 a-year.

Since 1817 a deduction has been made of L.90,331,196 from the principal of the debt, and L.6,594,920 from the interest on its account. This diminution has been principally effected by taking advantage of the fall in the rate of interest since the peace, and offering to pay off the holders of the different stocks unless they consented to accept of a reduced payment; and had it not been for the highly objectionable practice already adverted to, of funding large capitals at a low rate of interest, the saving in this way would have been incomparably larger.

Sinking fund.

A sinking fund for the extinction of the public debt was established by Sir Robert Walpole as early as 1716; but it was virtually subverted in 1733. It was again instituted by Mr Pitt in 1786; and, singular as it may now appear, it was for a lengthened period supposed that, by means of the *legerdemain* operation of compound interest, the public debt might be reduced by borrowing money to pay it off. Dr Hamilton of Aberdeen has the merit of having dissipated this extraordinary delusion, the grossest, certainly, by which any civilized nation ever suffered itself to be imposed upon. He showed that the excess of revenue over expenditure is the only real sinking fund—the only means by which any portion of the public debt had ever been, or ever could be, paid off; and that all sinking funds operating at compound interest or otherwise, excepting in as far as they happened to be founded on this principle, were mere quackery and delusion. In fact, upon examining into the matter, it was found that the public debt would have been decidedly less had the sinking fund never been heard of. After such an exposition, the existence of the sinking fund was impossible; and having undergone various modifications, it was finally abolished by the 10th Geo. IV., cap. 27, which enacts that the sum thenceforth annually applicable to the reduction of the public debt shall consist of the *actual surplus revenue beyond the expenditure.*

XV.—*Population.*

The population of England and Wales at periods antecedent to 1801 can only be determined by computations founded on the returns obtained under poll and hearth taxes, and on the registers of births and deaths. Unfortunately, however, none of these affords data from which the amount of population can be accurately deduced. During the latter part of last century the uncertainty in which this subject was involved afforded materials for a keen controversy, which was carried on by Dr Price on the one hand, and by Mr Howlett, vicar of Dunmow in Essex, and Mr Hales, on the other. The former contended that population had been declining in England from the Revolution downwards, and that it did not in 1777 exceed 4,763,000. Mr Howlett, however, showed conclusively that no reliance could be placed on either Dr Price's facts or arguments; and that there could be no reasonable doubt that the population had materially increased in the interval between 1700 and 1780. The returns obtained under the population acts put an end to this controversy, and proved the general accuracy of Mr Howlett's conclusions. The population, as deduced from them, after allowing for their defects and inaccuracies, is as follows:—

Years.	Population of England and Wales.	Years.	Population of England and Wales.
1700	5,475,000	1780	7,953,000
1710	5,240,000	1790	8,675,000
1720	5,565,000	1801	8,892,536
1730	5,796,000	1811	10,164,256
1740	6,064,000	1821	12,000,236
1750	6,467,000	1831	13,896,797
1760	6,736,000	1841	15,914,148
1770	7,428,000	1851	17,927,609

The population for 1801 was determined by actual enumeration; and since then censuses have been taken in 1811, 1821, 1831, 1841, and 1851, the results of which are embodied in the following comprehensive table:—

Statistics.

Population, and its Rate of Increase, and Value of Property, in the Counties of England and Wales, 1801–1851.

Counties.	1801.	1811.	1821.	1831.	1841.	1851.	Increase per Cent. in 50 Years.	Annual Rate of Increase per Cent.	Value. Amount of Real Property Assessed to the Property and Income-Tax, for the Year ended April 5, 1851.[1]	Value. Amount of Property Assessed to the Relief of the Poor for the Year ended March 25, 1850.[2]

Rate of mortality, &c.

Notwithstanding the defective state of the registers of marriages, births, and deaths, the results deduced from them are such as to establish beyond all question the fact of an extraordinary improvement having taken place in the healthiness of the mass of the people. Although about 919,000 were added to the population of England and Wales in the interval between 1780 and 1800, the annual average number of burials did not differ materially during that period.[1] It appears from the returns, that in 1780 the rate of mortality in England and Wales was one in forty; meaning by this, that one fortieth part of the whole population died annually. In 1790 the rate of mortality was reduced to one in forty-five. During the five years ending with 1800, it was one in forty-eight; during the five years ending with 1810, one in fifty-one; and during the five years ending with 1820, it had sunk to one in fifty-seven. During the five years ending with 1830, it seems to have slightly increased; having been, at an average of that period, one in fifty-four, but in 1851 it was one in fifty-six.

This extraordinary decrease of mortality is no doubt owing to a variety of causes; such as the greater prevalence of habits of sobriety and cleanliness; the better lodging, feeding, and clothing, of the labouring classes; improvements in medical science, &c. But to whatever it may be owing, it affords unquestionable evidence of the signally improved condition of the population.

The increase of longevity has been particularly conspicuous in London and other great towns. During the first half of last century, the mortality in the metropolis is believed to have been as high as one in twenty-four; and it required, down to the American war, large supplies of recruits from the country to keep up its numbers. But from 1770 the rate of mortality has been gradually diminishing. In 1790 the births for the first time exceeded the burials; and since then the city would have gone on increasing, though it had not been indebted to the country for a single immigrant. In Manchester, Bristol, &c. the improvement has been equally striking.

The proportion of births and marriages to the population has continued pretty nearly stationary since 1790. We subjoin abstracts from the tables of births, marriages, and deaths, registered in England during the year 1852.

Abstract of Marriages, registered in England, pursuant to the Act of 6th and 7th Will. IV., cap. 86, in the year ending December 31, 1852.

Marriages registered in Quarter ending last day of	
March	32,977

PART III.[1]

GOVERNMENT AND LAWS.

I.—Government.

Formal constitution.

"By the constitution of a country, is meant so much of its law as relates to the designation and form of the legislature; the rights and functions of the several parts of the legislative body; the construction, office, and jurisdiction of courts of justice." This is the definition given by Paley. It seems necessary to add also, "whatever prerogatives are vested in the executive;" at least, in case any powers and privileges are conferred on it beyond what, from being indispensable to the administration of the public affairs of a community, must be common alike to all executives. Even with this addition, the mere mechanism of a government, in the three principal relations which it bears to its subjects, is all that is here described. Yet something more is generally understood by a constitution, and would seem to be properly comprehended under that name. A government, it is true, may and must be influenced in a hundred ways by independent circumstances, and by manifold considerations, which are no part of it. But when certain specific tendencies and principles are directly and designedly moulded into its original conformation as so many distinct ends and maxims, or when they are subsequently developed by it or incorporated with it, so as to guide and qualify its spirit, they become entitled to the character of constitutional as much as the organization itself. There is no doubt that the mechanism of a government, if left to itself, will mainly determine the nature and direction of its movements; yet this mechanism consists of a moral and intellectual agency. It is accordingly capable of accommodating itself, and of working in subjection to whatever rules and impulses may be impressed upon it by the society whose instrument it is.

No society can be so stationary but that changes must take place, sooner or later, for the better or for the worse, in some one or other of the conditions, whether of principle or of organization, which make up its constitution. When these happen to take place, hardly any society can have been so judiciously constructed from the first, or be so fortunate in all its future circumstances, that lawyers shall be able at once to call every change which is for the worse unconstitutional, and which is for the better constitutional. An approximation to this favourable situation has been one of the great and innumerable advantages of the uniform and gradual progress by which the English constitution has been distinguished. Its history is the history of the internal policy of a people, who at every advance in civilization succeeded in occupying one advanced post after another, fortifying their free position at every remove. The early prospect would have discouraged the most sanguine philosopher. But the evil tendencies were suppressed, and the good ones brought forward, until the process appears to resemble the natural development by which a germ grows up into a plant, with but little occasional help from the pruning hand of man. Precisely the reverse might have happened. It is what takes place during that imperceptible decay, which, by a foolish analogy to vegetable and animal life, it has been supposed that institutions are also destined to undergo. The bulk of mankind more easily perceive that abrupt and extensive changes, the innovations by which new principles, or a new organization, are introduced, amount in fact, as far as they go, to a new constitution. This may be done legally or illegally. If illegally, it is a revolution; a case which by the supposition has nothing to do with law. If legally, the letter of the law and the forms of the

[1] For this part of the article the Editor is indebted to William Empson, Esq. Professor of the Laws of England at the East India College.

constitution may be used for the purpose of substituting a worse as well as a better government to the extent that the ancient constitution is displaced. The question, what name will most properly describe any specific measure of this class? must depend upon the nature and degree of the measure. There is on these occasions another question for a people, prior in time, and far more important than discussions about a name. It is their duty to ascertain whether the proposed change is, under all the circumstances, a practicable improvement, and to fix where the authority for deciding this point can, upon the whole, be most safely lodged. A comparison of the different methods by which the latter problem can be solved will show what little cause there is for maintaining, as some modern writers are disposed to do, that the course adopted in England is too loose and arbitrary to be consistent with the positive character implied in a constitution.

Three very different systems may prevail in this respect. The two first are alluded to rather than recognised in English history. Its whole tenor proceeds upon the last.

Every country has at one time or another given more or less countenance, upon some favourite points, to the delusion of fundamental laws and unalienable rights; meaning by these, laws and rights incapable of alteration, except by a violence or decay equivalent to the suspension, if not dissolution, of society. Confounding the principle of moral and of legal obligation, Chief-Justice Hobart, from the bench, and Blackstone, calmly writing in his closet for the instruction of the eighteenth century, concur in stating that the supreme power of every state is necessarily subject to one condition. By this condition, all legislative commands against natural justice must be void in themselves, that is, void in law. With much less latitude than has often been given to the law of nature and to the rights of man, this exception might be made to cover extensive and dangerous ground. Lord Coke, for example, has said, that a statute against Magna Charta, or one to prevent the Irish from coming into England, would be void. In this manner the Stuarts were taught by servile judges to believe that most of the prerogatives anciently affixed to the crown were irrevocable even by act of parliament. A similar opinion, grounded on the doctrine of the three estates of the realm, was formerly propagated concerning the episcopal right of sharing in the legislature. At the Reformation, Bishop Gardiner conceived, that in consequence of the forced absence of himself and his brethren, its proceedings would be of none effect. The example was followed, but equally in vain, when, during the violent re-action provoked by Charles I., who considered himself as so pre-eminently a Church of England king, the bishops protested against all acts passed in their absence by a parliament no longer free. Charles I. held the very act by which the bishops were excluded, although some of them attended and voted against it, to be *ipso facto* null. The more intelligent a nation really becomes, the less likely is it thus to presume in favour of the political optimism of its own or of former times. No fiction can be more gratuitously mischievous than the creed that there can be any thing in the force of invading arms in 1066, or in the authority of national wisdom in 1688, or in any length of prescription whatsoever, to disable successive generations from exercising their own discretion respecting the propriety of their existing institutions.

Another plan is to set apart, in a written charter or declaration, certain excepted cases. The high matters which are the chosen objects of this deliberate sanction, are conceived to acquire thereby the privilege of being placed beyond the control of the ordinary legislature, and of being reserved for the direct volition of the body of the people. Locke, in treating of the right of popular resistance, seems to have stated too broadly, that the power of a community can never be exercised in this manner under any form of government, because such a proceeding, he says, presumes the government to be dissolved. Blackstone (vol. i. p. 161) expresses himself still more strongly to the same effect, adding, that no government will presuppose its own destruction. The contemplated occasions are neither as extreme in theory nor as impracticable in execution as this language would represent. There is really no question in this case about resistance, nor what can reasonably be called dissolution. Whilst, on the one hand, the law has nothing to do with possibilities belonging to the ultimate and latent right of resistance; on the other, the idea of a supreme power which may be lawfully resisted in points where it is called supreme, is of course a contradiction. Thus in an absolute government society must be remitted to its first principles before the right of popular interposition can be recognised by it. An ordinance of Louis XIV. declared that the extinction of the family of Bourbon would raise a case of this kind, and that on the occurrence of such event the right of electing to the crown of France would revert to the French people. But limited governments stand in an entirely different position. Minor contingencies, far short of the transgressions which justify an appeal to arms, or of the accident which summons a nation to the *Champ du Mars* to agree upon a successor to a vacant throne, are part of their necessities. The entire legislature may be only supreme *sub modo*. For under the doctrine both of fundamental laws and constitutional charters, every variety of restriction may be imposed upon the legislature. The prudence of these restrictions is more than problematical. But wherever a government consists of several parts possessing co-ordinate authority, the demand for some external control necessarily arises; since encroachments of one part on the other must be expected; and means ought to be arranged beforehand for bringing them back peaceably within their proper limits.

In this manner, wherever the doctrine of fundamental laws is admitted, a sufficient authority, as, for instance, a high court of justice, should be created for the purpose of inquiring into and correcting any violation of them with which the ordinary legislature may happen to be charged. It will be necessary, besides, to chalk out, as in primary assemblies or otherwise, the extraordinary course by which the policy of the fundamental laws themselves may be reviewed, as occasion shall require. Both these precautions have been introduced and satisfactorily applied by the founders of the United States. But they are not wanted for this purpose by the English constitution. For, notwithstanding a few fanciful conjectures, as above, at times incautiously or intemperately hazarded, the English constitution is not established on any strictly fundamental laws, and still less are any specific questions reserved by it for the direct intervention of the people. But there are analogous dilemmas which may arise under it as a limited and a mixed monarchy. Many, indeed most, of these dilemmas appear to be left open to the chances of unnecessary aggravation, by the want of some similar arrangement. A government, composed of several members with distinct powers, can only exist as such on the supposition that they each remain content with their own share, or that, in case one should trespass on the other, the irregularity can be set right by recurring to expedients legally providing for the emergency. Every one of the triple divisions of the English legislature has in its turn made experimental encroachments, against which there exist but imperfect and often very circuitous guards in the constitution. By the law of constructive contempts, once so flagrantly abused, either house of parliament is armed

Government and Laws.

with a despotic weapon. This weapon is beginning to gather a prudential rust in the sheath at present; but the want or the jealousy of a superior court is a poor excuse for allowing it to continue there at all. The mysticism belonging to the maxim that the king can do no wrong, coupled with the recognised absence of any remedy against the crown for any possible amount of misgovernment, proved the ruin of the Stuarts. It encouraged them in the opinion that the supreme power was lodged, not merely in part, but wholly, in the sovereign, and that it might be abused with legal impunity. The 16th Charles II., as renewed by 6 William and Mary, declares that a new parliament shall be called within three years of the determination of the former; but no measures are taken by either statute for the assembling of a parliament in case the king should not choose to call one. The security is left to the old indirect check, the stoppage of the supplies, and to the new one, which, by means of the annual mutiny act, has been derived from a source where an aid to freedom could hardly have been expected, namely, the innovation of a standing army. There is at present abundance of rectifying principle and of auxiliary appliances in the sounder portions of the English constitution, which will prop up the rest, and hold the feebler part to its work. Otherwise the history of the Habeas Corpus act is a striking proof of the inadequacy of all general declarations. In doubtful times these are merely waste paper, unless accompanied by positive arrangements for carrying them into execution, and subjected to proportionate penalties on their infringement and neglect. The act of 16 Charles I. had provided, that if the king neglected to call a parliament for three years, the peers might assemble and issue writs for choosing one; and, in case of neglect by the peers, the constituents might meet and elect one themselves. This act was repealed with great ignominy at the Restoration. But it seems to have left the crown its due precedence, and to have provided, with as little impatience as possible, for the securing an object which all parties are agreed it is absolutely necessary some way or other to secure. The debates upon the command of the militia previously to the breaking out of the civil war, are a memorable instance of the folly of leaving great constitutional rights in obscurity up to the fatal hour when they can no longer be settled calmly and on reasonable terms. If it be important to define rights in times of tranquillity, it is no less so to provide the particular forms by which, in case of violation, the remedy may be applied. It is true that these collisions approach to the character of revolutions. When a king has so far separated himself from his parliament, there is little chance of their returning to that harmony by which alone a constitutional monarchy subsists. No previous arrangements can completely meet the crisis after it has occurred; but they may mitigate its severity, and, by the mere fact of their known existence, may do the still more acceptable service of preventing its occurrence.

According to the third and remaining plan, the constitution recognises the existing legislature as supreme for all purposes whatsoever. To this plan the English nation has always stedfastly adhered. From the time when the commons of England were adopted into the legislature (49 Hen. III.), or shortly afterwards, the legislature has, without any deviation worth mentioning, been the parliament; that is, the king, lords, and commons, in parliament assembled. The popularity of parliaments has been so paramount throughout, that the public have never until recent times been tempted to look elsewhere for rules, inclinations, or opinions. The supremacy of parliament kept its hold, like an anchor which nothing could shake, in the most stormy seasons, and under every variety of circumstance. The impossibility of complying with the customary forms was satisfied as often as it occurred, by the nearest approximation which could be obtained. This was no less remarkable in the course taken as far back as the supposed resignations of Edward II. and Richard II., than on the later occasions of the imperfect convention parliaments. Nobody suggested the propriety of calling together the people to restore Charles II., or to instal William III. into the vacant throne. Mr Hallam observes, that in the combination of gift, descent, and popular election, which took place on the accession of Henry IV. in the year 1399, there was as great formality as in 1688, making due allowance for times and men. The semblance of election remained with the members of the *quasi*-parliament. They had been summoned by the king's writ, but, from not having his commission, they did not take that solemn name, and only called themselves the estates of the realm. Wherever it was possible to preserve by fictions the appearance of a regular parliament, fictions were called in. Thus, during the infancy of Henry VI. the shadow of the royal infant, then only nine months old, opened his first parliament, and made appointments during pleasure. On the derangement of George III. the regency was appointed under the great seal. To keep up the entireness of the body politic of the state, the co-operation and personal will of the king were necessarily assumed in the very act which was to supply his personal incapacity. It was from the court of parliament that Richard III. obtained a confirmation of his alleged title. He rested upon it as "the known quieter of men's minds;" and the Earl of Surrey appealed to it as the one conclusive authority, when taunted afterwards by the successful competitor for the crown upon Bosworth Field. Though Wolsey, "hating parliaments," which therefore hated him, "had been the means that none was holden in the realm but one for the space of fourteen years;" yet Henry VIII. told them that he was informed by his judges that he was never so great as when sitting there in his estate royal. The great test of the omnipotence of parliament was its power of altering the succession. This, which was the established doctrine of the prior period, it was by a statute of Elizabeth made treason to deny. At the beginning of the civil wars, Charles I. called the peers together at York; and the cavalier members seceded from the House of Commons. Under these circumstances a metaphysical question might easily have been raised, as to which was the real parliament. But the locality of Westminster was like keeping the field of battle. It decided the direction of that wonderful and superstitious homage, which made Clarendon complain that "an implicit reverence for the name of parliament was the fatal disease of the whole kingdom." The substance and vitality, however, of the institutions to which the entire authority of national legislation is transferred, are still more important than the name. For this purpose their independence as intelligent deliberative assemblies must be secured. No question can be made concerning open violence. Any attempt by intimidation to force the repeal of a law or a change of measures, or to overawe either house, is treason. But, further than this, no minority or fraction of the people must be allowed to exercise over the legislature an influence of opinion, which the constitution does not attribute to the people at large, or at least does not provide them with the means of exercising. This is a subject of great delicacy; but still there must be some limits. Accordingly, both in law and practice, limits more or less elastic have been put on the nature and degree even of the moral pressure which may be urged on parliament from without.

Tumultuous petitions having been carried to a great

Government and Laws.

excess during the long parliament, the statute 13 Charles II. in consequence, imposed several restrictions upon petitions for any alteration in church or state. But notwithstanding the opinion of Mr Dunning, and the present practice, these restraints have been judicially determined not to be affected by the bill of rights. Mr Hallam says that he has traced public meetings for the debate of political questions no higher than the year 1769, and, subject to very few exceptions, petitions simply political not quite so high. Rights of this kind, guaranteed to the body of the people, and liberally construed, appear to be supplemental to a representation which stops short of annual parliaments and universal suffrage. They are the democratical counterpart to addresses of loyalty to the throne, and of confidence in the government, which are said by Evelyn to have come in even in the time of Cromwell. The right will probably not be used, certainly not used frequently, till a want of sympathy between the representative body and the people, or particular classes, begins to be suspected. The sense of the public, so taken, may often be found to clash with the sense of particular constituencies. In this case, two questions necessarily arise for a member's consideration: first, what weight either one or the other ought to have as mere authority in overruling his own opinion; and, next, which of them, in the event of competition, is entitled to a preference. The same constitutional answer will apply to both difficulties. The inclination on the part of the English constitution appears to have settled down, after some previous oscillation, to one consistent course, as soon as the commons began to feel and act up to their real dignity and strength. A member must necessarily be returned for a particular place. The question is, Are his duties therefore local? The terms of the writ of summons had all along plainly signified that, although chosen by a single district, he was chosen for the wants and service of the realm. Nevertheless many instances formerly occurred of the commons begging for time to consult with their constituents. It may naturally be presumed that this was nothing more than a timid way of evading unreasonable requests. Because their ancestors, afraid of Edward III.'s designs upon their subsidies and fifteenths, had declined to be made consulting parties to his wars, it was absurd in James I. to imagine that he could altogether call away from politics the English gentry of his day. Yet at so late a period no less a person than Burghley condescended to argue against the propriety of the interference of the House of Commons in matters of war and peace; and to take the distinct ground that its members by its institution had minds only of a compass each for the place which he served. But parliament had already heard the contrary within its walls. The movement of society which had made it impossible to execute the statute requiring the member of a district to be an inhabitant, had brought out, in the reign of Elizabeth, the first parliamentary declaration in behalf of the complete legislative authority of members of the House of Commons, in full accordance with the letter and conditions of the ancient writ. In the declaration that members were to act not only for their constituents, but for the whole kingdom, it was evident that a great principle was proclaimed. If sycophants then contested it, Mr Hallam, speaking of modern days, says very truly, that it is one which at present "none but the servile worshippers of the populace are ever found to gainsay." The weightiest arguments in Burke's letter to the sheriff of Bristol, against particular instructions, are little more than the application and extension of this principle. The necessity of going back to their constituents for a specific assent, was one of the main grounds of that incompetency to the duties of a representative assembly which facilitated the ruin of the states-general of France. A few votes beyond what a question would have obtained upon its general merits may thus be stolen, and a few individuals may thus push themselves forward into temporary notice. But public opinion can never be truly ascertained, any more than the public interest comprehensively promoted, by desultory and individual pledges. For this purpose the public must act in concert. With this view, kings of England have sought to satisfy themselves and the House of Lords with regard to the reality of the public sentiments, by a dissolution addressed to specific points. On the occasion of Mr Fox's India bill, the new members were expected to bring to the House of Commons an answer concerning the royal choice of particular men as ministers; and on the occasion of the Reform Bill, concerning the policy of a particular measure. This is the utmost advance which the English constitution has made towards admitting the doctrine of the will of the people or the instructions of constituents. So narrowed, it is a proper, and at times an indispensable part of every rational system of representation. It is practically quite consistent with the general rule that the select body of electors are trustees for the entire community; and that their representatives are the only organ by which the public will is on all subjects ultimately and conclusively expressed.

This then is the English system. It seems to be an extreme and fanciful subtilty to doubt whether the title and character of a constitution can properly belong to it. It is something in its favour that it can appeal to experience as practically embodied in a government, now of ancient standing, at once the most progressive and the most permanent which the world has ever yet seen. Why is it less a constitution because it gives to its ordinary contemporary legislature the most plenary attributes of supreme political power, and because it disclaims the supposition that its early constitutional legislation had or could have the sanction of any higher authority? The assent of any one generation can be of neither greater nor less value than that of another. It is not wonderful that a society, setting up for itself for the first time, or obliged by circumstances to begin anew in an enlightened age, should try to build upon the basis of fundamental laws. But it is fortunate for a constitution, of which the first stone was laid in haste and ignorance, and in the dark, and which nevertheless always kept so far in advance of its contemporaries, as to serve other nations for the model whence the criticisms have been derived by which its irregularities were afterwards to be condemned, that it started with no similar pretensions. If it were to suit the ages through which it was to endure, it could only do so by a plastic mode of conformation. In this manner its people were educated along with it and up to it, the two acting and re-acting upon each other. Hence an instinctive intelligence and conformity, otherwise almost unattainable, appear to have been secured, which political changes have hitherto slightly disturbed. Some bad logic, and a few incidental anomalies, are a small price to pay for conciliating opinions and smoothing over the transitions through which, in the course of centuries, an improving nation has to pass. But the mode in which these alterations have been made is objected to. The body of the people, it is said, ought to have legislated upon them in their own persons. It is surely a sufficient answer that it would be difficult to name a year, when in point of fact more would not have been lost than gained by tying up the hands of parliament, and putting its legislature to the circuity of an appeal to the freeholders of the county courts. The nature of things does not admit of there being any greater security for good government than can be given by a legislature of which a popular representative assembly, pro-

Government and Laws.

perly chosen and seasonably renewed, is a member. To call in the people to council, is to abandon to that extent, under circumstances too of great probable excitement, the advantages of representation; and for no countervailing benefit, unless on the singular supposition that a people incapable of choosing able and honest representatives, will be found capable of being able and honest legislators themselves. The device is much more likely practically to delay improvement than to check encroachments; since, for the latter purpose, the restraints it imposes are either unnecessary or insufficient. There can be no substitute for the spirit of a people. With that spirit, these precautions are not wanted; without it they are vain. The two cases which look most suspicious in English history (one in substance, the other in form) are the proclamation-statute of Henry VIII. and the septennial bill. The parliament of Henry VIII. gave royal proclamations in certain cases the force of law. The extent of the innovation has often been exaggerated. But, with regard to the present question, there can be no doubt, that a generation which by royal order changed its religion four times in twelve years, would, on the subject of royal proclamations, have as readily acceded to his majesty's desires. A few corporations petitioned against the septennial bill. But an observer of the prior, contemporary, and subsequent conduct of the body of the people on this point, and a reader of Burke's speech against triennial parliaments, will perhaps see little reason to believe or to wish that the people, if calmly consulted, would have come to a different conclusion. It should be recollected, that the question is one of pure argument only, and not of history. By the common law a parliament, unless dissolved, lasted for the king's life. In 1694 this duration was first shortened to three years; but in 1717 these three years were lengthened to seven. Thus, the law of triennial parliaments, spoken of by some as an almost vital part of the English constitution, was never known in England but for neither more nor less than the space of twenty and three years.

Every government is characterized by the ends which it proposes as its primary objects, and by the means which it applies for the attainment of its ends. These objects represent what is vaguely called its spirit. The only means properly at its command refer to the making, interpreting, and executing laws. It follows that the most important distinctions in this respect between one government and another, must be found in the specific provisions which determine the formation and distribution of the legislative, judicial, and administrative power. The English constitution is a limited or mixed monarchy; limited, by the maxim that the king has no rights but those which are prescribed and ascertained by law; mixed, by the fact that the parliament, in which the sole legislative authority resides, consists of the king and the three estates, the nobility, clergy, and commonalty of the realm, as comprised in the two houses of Lords and Commons. The suppression of partial interests is sought to be attained, and the practical recognition of the great end of government, namely, the happiness of the whole body of the people, has been principally developed and enforced by the share which the people exercise more or less in the government. This takes place in the legislative department, by means of their representatives; in the judicial, by the agency of the jury; in the administrative, by the doctrine of official responsibility, and from the example and control of a great diversity of popular local municipal institutions.

A more considerate legislation is promoted by a second legislative assembly. A great addition is also made to the political stability of a limited monarchy, by forming the members of this second assembly into an hereditary nobility. A mixed government has, however, a still greater advantage. It naturally leads to and facilitates a division of powers, which is the most important of all the checks that mere arrangement can produce. According to this division, the authority of parliament is strictly confined to the original enactment of the laws. The duty of the judges is as strictly judicial. They have no more to do with the politic administering of the law than with the making of it. The law being thus made, and thus interpreted, the entire charge of carrying it into effect is vested immediately or mediately in the crown. Whilst the several parties who make, interpret, and execute the laws, are kept, in this manner, perfectly distinct, it becomes exceedingly improbable that any confusion, either unintentional or wilful, should arise between the principles properly belonging to their several operations. This is a caution which the cause of public liberty, as well as that of civil justice, alike imperatively require. Blackstone[1] has expressed a strong opinion as to the propriety of the executive being only a branch, and not the whole, of the legislative; also[2] that the judicial authority should in some degree be separated from both. This was one of the points on the paramount importance of which Jefferson and Adams were agreed when they came to apply the experience of the English constitution to the construction of their own.

Eastern nations, notwithstanding their supposed immemorial civilization, appear never to have got much nearer than the inhabitants of the South Sea Islands to a conception of the just foundation on which alone the rights and duties of sovereignty rest. On the other hand, the citizens of Greece and Rome were fully aware that political society was grounded on the advantage of its members. Their patriotism was not more exalted by the pride of national independence than by the consciousness of being responsible only to the law. Nevertheless, the real condition of these great commonwealths was for the most part in lamentable contradiction to the individual ability and virtue by which their history has been made famous throughout all ages. The glory of free and classical antiquity was frequently clouded, and was brought at last to an abrupt and final termination. This is apparently to be attributed to the defective mechanism of their institutions, more than to any other cause. Their construction and division of the legislative, judicial, and executive authority were all along so imperfect, that their negligence of the means of a better political arrangement can only be accounted for by their ignorance of its necessity. There is nothing to this effect, even in their theoretical works upon government, when carefully examined. Polybius, it is true, gives the preference to a combination of monarchy, aristocracy, and democracy, as being in a degree more stable than the simple forms. Cicero also agrees with him in saying, that this was the true Roman constitution; but he most unwisely adds, in compliance with the Roman jealousy of kings, that wherever the executive is placed in a single hand, the government is mixed only, not tempered, and must be ruined by the vices of the individual. Different writers appear to have meant different things by the same word. Aristides denominated the government a mixed one as late as the time of Marcus Aurelius. Tacitus saw through the fictions, and thought that the word implied more, otherwise he would scarcely have said that such a combination may be more easily praised than effected, and that were it effected it

[1] *Commentaries*, vol. i. p. 146 and 154.

[2] *Ibid.* p. 269.

Government and Laws.

could never be lasting. In case, however, the constitution had done nothing further than realize the above combination in the general sense which alone these philosophical statesmen were contemplating, it would have stopped infinitely short of the principal benefits which it has conferred. The separation of the three great branches of political authority into distinct departments, as it is one of the most probable consequences of a mixed monarchy, so is it beyond all comparison the most valuable. Unfortunately it had not taken place under the imperfect specimens of mixed government with which they were acquainted. It is not surprising, therefore, that in theory the philosophical truth of such a corollary should never have occurred to them. If that consequence had been duly presented to his mind, Tacitus must surely have seen reason to question the cycle of Polybius, and to feel greater confidence in the political contrivance by which the efficiency and the durability of states have both been found in practice to gather equal strength. No political phenomenon can be more interesting than the circumstances and the method by which a government has thus arrived at the high distinction of first uniting improvement and stability, liberty and order, and has been enabled to combine the greatest of all ends with what, from the failure of the most celebrated experiments, it may be well supposed were means very difficult both to discover and to apply. Sanguine spirits often appear to imagine that as good a constitution as can be devised may be struck out and fitted upon at a moment's notice. The history of the English constitution may teach them greater caution. A distinct examination of its respective parts will show, not only how slowly they have been formed, but to what extreme risks at different periods the existence and the principle of each have been, and perhaps must be, severally exposed.

The English constitution is more historical than philosophical. It has been the gradual development of national good sense, shown in a spirited and prudent improvement of tendencies and events, without any of the ambition of a regular, preconcerted system. Its object was never stated in a declaration of the abstract rights of man, nor its organization derived from a metaphysical analysis of the elements of human nature. He must have been indeed a prophet, who, at the time of the Norman conquest, could have foreseen the course by which it would outstrip the feudal monarchies which resembled and surrounded it. The difference lay in this: For successive centuries, circumstances played favourably for a people who had the merit or the good fortune to profit by them as they occurred. M. Rey is so far right. England has experienced the truth of Aristotle's observation with regard to Crete. An insular position has great advantages for political experiments. Assistance has also frequently come in from the most unlikely quarters, and the scale has more than once been turned by causes to which, as far as we can observe, no nobler name than that of accident is to be assigned. At one time the very strength and concentration of the monarchy of England, as compared with the weakness of the monarchy of France, brought the barons, the people, and even the church, into a closer union for their defence. At a later period the impoverishment of the crown by foreign wars, and the alienation of the crown lands, brought it into dependence upon, what was most fortunately, one national parliament instead of several distinct provincial assemblies. The separation of the greater from the lesser barons, the assembling of the commons and the lords in different chambers, the transit through which the exemptions claimed by the clergy became disqualifications, the conversion of the jury from their original character (whatever that may have been) into a popular tribunal, have turned out to be the hinges on which English freedom has ultimately turned. They are instances of incidents, in themselves at first comparatively trifling, diverted by circumstances into a deeper channel, or transmuted by a noble alchemy into a much higher purpose than what was their original purview and intent. Although the English government was from the first a limited monarchy, it was not for nothing that monks and lawyers lent a hand in the pious frauds of forging tales about Alfred, Kentish privileges, and imaginary Saxon laws, or in encouraging the more recent fiction of the notorious anti-tallage statute. . The stoutest antiquarian who ever argued that the title of William the Conqueror represented merely the feudal *conquisitio*, and not the conquest of the nation, nevertheless must admit from time to time great historical distinctions. The nature and degree of the limitations practically needed and applied to the powers and mechanism of the several component parts of the government varied exceedingly at different periods. The importance even of the grand division between the legislative, judicial, and executive authorities, was far from being at once recognised and observed.

Changes in society and opinion.

A constitution upon paper and in practice are such very different things, that we must look into the history as well as the laws of a country, in order to know at any given time what was the real contemporary character of its government. English antiquarians have been more or less successful in tracing back the dates of their most popular institutions. But the sense in which the same institutions were in point of fact understood and administered at different periods, and the security which they were capable of affording, are distinct and much more interesting questions. A people and their government, it is true, are always cause and effect to each other; and none more so than those of England. In the present instance, however, there can be no doubt but that the narrative of English parliaments and of English juries establishes their existence, as a matter of pedigree, long before there was spread throughout the community either the spirit, the knowledge, or the means to turn them to their legitimate account. The systematic regularity of modern governments was unknown even to the ancient republics. No wonder, therefore, that it was wholly unthought of either by the feudal chieftains themselves, or by the rude vassals who attended to do suit and service at their courts. Our ancestors were satisfied, we are told, with the rough standard of measurement taken from parts of the human body, though differing in different men, till Henry I. ordered the *ulna* or ell, which answers to our modern yard, to be made the precise length of his own arm. To lay down any thing like a precise standard for civil obedience, was left for later times, and for arms still stronger than those of any king. Even long after the golden rules and metewand of the law were recognised at Westminster, acts of violence were frequent over the kingdom, with more or less remonstrance; so that *judicandum est legibus non exemplis* is a maxim which the constitutional inquirer is obliged to keep constantly before him.

The history of England opens with a society divided into castes. The distinctions taken by the law were onerous and severe. There is a great difference between Glanville and Beaumanoir. Nevertheless, the blot upon Magna Charta itself, in the limitation (*liber homo*) cannot be explained away. The later threat of Richard II. after the unsuccessful insurrection to which the peasantry had been driven by oppression, is equally intelligible. Their condition, he told them, should be made yet more miserable. The statute of labourers, which was passed in the reign of Edward III., was in the same spirit. It continued to be a no less absurd than wicked favourite with after-

Government and Laws.

times. It is impossible to look over the whole intermediate legislation concerning the lower orders down to the reign of Elizabeth, without perceiving that most of its provisions are as much statutes of police as of trade. They have the air of being expressly directed to the object of preventing the consolidation of the different degrees of society into one people. When we compare the laws of England in this respect with those of the continent, we cannot estimate too highly the comparative equality of ranks, and the absence of exclusive privileges. Nevertheless the laws were bad, and public opinion worse. The dialogue on the Exchequer, written towards the close of the reign of Henry II., observes, that in all cases of secret slaying, whether of English or Norman, the penalty should be levied on the hundred, "unless there are plain *indicia* of the servile condition of the deceased." The petition of the commons to Richard II. that villeins might not be put to school and so get on in the church, "for the honour of all freemen," was re-echoed two hundred years later, in the cry against the Lord Cromwell, on account of his "villein blood." The class was then about to disappear. It is evident that it was only by its extinction that prejudices incompatible with real equality under a free constitution could be removed. The gradual elevation of the entire population into the condition of freemen, put all ultimately in possession of rights which had been wrested from the crown by feudal leaders and independent yeomen with a much more partial object. It took ages to compass this emancipation, and to reverse the proportional shares of the national wealth, as held by the king, the church, the nobility, and the commons. If all the land of the kingdom had continued to be the portion of the church, the king, and the immediate tenants of the crown, who, according to the list in Domesday-book and Brady, did not exceed seven hundred in number, this consummation would never have been accomplished. Civil wars and commerce, by scattering properties and displacing chivalry, broke up the feudal system much more effectually than any positive enactment. The possession of property gave leisure; leisure, especially when the reformation and the press stirred up the human mind with new and more liberal excitements, gave knowledge. Even without the strength of numbers, the combined influence of property and knowledge must give power. Until the body of a people has obtained the intelligence necessary to understand something of their own interests, and the power of making an attention to their interest and feelings a matter of prudence on the part of the higher classes, it is in vain to expect that just principles of government will be steadily acknowledged, much less that they will be steadily put in practice.

The king appears in the law-books as the source of almost every institution and every right. There is no other independent political existence save his baronial court. Nevertheless, as far at least as concerned the people, the king was originally still more powerful in fact than even in law. There was always a legal control upon him. But it was lodged at the beginning in an assembly where as yet the people bore no part. Bracton, who wrote under Henry III., probably not long before Leicester's writs to knights, citizens, and burgesses, appears to have as little anticipated them as he could have anticipated their effect. In his perversion of the imperial law to the purposes of a limited monarchy, he declares that the will of the prince must be according to his counsellors; that is, of "his court of earls and barons." He terms them his "associates," and makes them his superiors; for he adds, "were the king without a bridle from the law, they ought to put one on him." The court of peers, or royal council of France, by the non-attendance of the tenants in chief, sunk into the great judicial tribunal of the country, and became known by the name of parliament, after the time of St Louis. The peers of England were not so confident of their feudal exemption from supreme legislative control; consequently, when, about the same time, or a little earlier, the *aula regis* or great council of England assumed a new form, it separated into two compartments; one judicial, or the supreme courts of justice; the other legislative. The last consisted originally of the earls and barons only. By the time that the incipient House of Commons became its colleague, the name of parliament was appropriated, and, from its omnipotence over the feelings of the English nation, has become almost consecrated in their behalf. It was long before the parliament felt its strength, or knew how to use it. In the mean while the constitution, directly or indirectly, within doors and without, kept making head. During the struggles which the crown, reign after reign, was maintaining, sometimes with different members of the royal family, at others with the aristocracy, and at others against the church and papal usurpations, the people became important as allies. The people appear on the whole to have judiciously sided, where, according as the temporary pressure was felt to bear, it was for the interest of the public that they should side. It is difficult, owing partly to the uniformity which prevails at present, to comprehend the sudden turns which this instinctive policy might call upon them to make.

A sagacious and honest yeoman may have been with King John to-day, and with his barons to-morrow. To look merely at property: the Conqueror retained in his own hands fourteen hundred manors, the reserved rents on which Burke, in his Abridgment of English History, reduces to L.70,000 of the money of that period. The resumption of the grants of Henry VI. was prefaced by a public declaration that his ordinary income did not amount to more than L.5000. In the next reign we find Edward IV., independently of parliamentary supplies, the owner of above a fifth of the lay property of the kingdom. Within half a century the scale had again changed its balance. Wholesale confiscations, succeeded by the minuter and more politic arts of Henry VII. humbled the pride and broke the combinations of the nobility. Although the nominal rental of the royal demesnes was reduced to L.32,000 at the accession of James I., yet the idea of any danger to the monarchy from aristocratical competition was almost a faint tradition at the time of Lord Russell's trial. He justly exclaimed, in allusion to the apprehension, "We have no great men now." Previously to this revolution in society, it depended for the most part on the personal capacity and character of the sovereign, whether the contingencies to which a wise constitutional jealousy ought to have been most alive, would come from the turbulent intrigues of the aristocracy, or from monarchical ambition. The royal prerogative attracts the first and the liveliest attention, as its power is always present and most promptly felt. Besides, it was absolute in language, prominent in form, and often irritating in the subject and occasion of its exercise. But all the great points whence a cloud might have arisen over the freedom of the nation had been soon foreclosed, and, in spite of occasional, indeed numerous violations, were closely watched. There is no denying that many remaining prerogatives were absurd and even odious. Still the nature and the danger of the grievances to which the people were legally and practically exposed from them are usually overrated. The Stuarts let no prerogative drop willingly; and it is well known that they laboured hard to revive some that were obsolete. Yet Lord Bacon declared, on presenting an address to King James, that there was no grievance in the kingdom "so general, so continual, so sensible, and so bitter, as the preroga-

tive of purveyance." Nevertheless, what did it amount to when represented in money? From one cause or another, the commons receded from their negotiation, rather than buy off this their master grievance, and that of military tenures into the bargain, at the cost of an annuity of L.200,000. In the interval which elapsed between the depression of the nobles and the rise of the commons, the monarch had the stage comparatively to himself. The crown also at that critical moment passed into a line of able and haughty princes. Mr Hallam observes, that constitutional freedom was consequently retrograde from Henry VI. to VIII.; yet it is evident, from what passed during that period, that the hardy plant was not only alive, but safe. Bills in the form of acts, instead of petitions, which by adding to or diminishing from what the commons had petitioned for, had been for ages scandalously abused, begin with the reign of Henry VI. The first writ of habeas corpus, apparently so simple a result of Magna Charta, was obtained against Henry VII., the wiliest of the Tudors. Elizabeth had her father's spirit, and can scarcely be suspected of relaxing a hold which she could have decently retained. Yet in 1586 the House of Commons first succeeded in bringing the inquiry into election returns from out of chancery before themselves. By unfairly selecting the arbitrary passages from the reign of Elizabeth, and misrepresenting them as the ordinary course of her government, Hume gave both colour and currency to sophisms, which betrayed a much greater passion for ingenious paradox than for historical truth. The English people are wrong, it seems, in charging the Stuarts personally with the misgovernment which provoked the great rebellion. That misgovernment is represented to be nothing more than a continuance of the ancient English constitution, such alone as their ancestors had known it. According to this statement, the fault of the Stuarts would have consisted in carrying down the prior constitutional misrule into times which would no longer bear it. If such had been the fact, it is a fact which those times must certainly have known. But the understanding of contemporary parties was plainly all the other way. History has preserved the positive admission of Charles I. to the contrary, in a reference too remarkable not to prove that he was himself conscious of, and was aware also that his subjects knew, the whole extent as well as spirit of his innovations. What a satire on his own and on his father's government, that he should, in 1640,[1] hold it out to his parliament as a boon, that he would return to the precedents of a sovereign whom they had already endeared to the people as "Good Queen Bess;" whose reign, however, we know, notwithstanding, to have abounded with tyrannical executions, gross and frequent enough, it might have been thought, to have satisfied any of her successors. It is not the less true, that the time had come when the authority as well as the ceremonies of the court must undergo mutations, at which minds, with much larger views of government than that of Clarendon, would be startled, and perhaps annoyed. The state of society required popular changes to be admitted, for which no precise precedent could be found. Under these circumstances, men like Selden, for instance, a little too apt not to look for liberty beyond their law-books, must often have felt embarrassed how to act. The Stuarts, however, did as much as could well be done towards relieving their subjects from difficulties of this description.

Unluckily for the Stuarts, none of the innovations which they attempted, nay not even the consistent system to which it had been their object to bring the practice of their government, were so new and so outrageous as the principles on which they professed to reign. No country set a higher value than England, whether it was pleaded on behalf of the prerogative royal, or in the much more reasonable case of civil possessions, on the somewhat too stationary title of prescription. The coronation oath on the one hand, and the oath of allegiance on the other, the theory of the feudal system, and many passages in their annals, had accustomed them to look to a rough notion of contract as the criterion of submission. The divinity studies of the early lawyers, and the usages of the puritans, tended to influence the thought and language of modern times by the course of authorities in the Old Testament. But these views were common property. All went there for what they wanted, and all found it. The partizans of despotism and freedom, Hobbes and Locke, Bossuet and Algernon Sidney, discovered, the two first in Chronicles, the two last in Deuteronomy, arguments for their opposite systems. It was far otherwise with the novelty which the Stuarts took up, and made the creed of their supporters. The new creed was precise and positive, and the whole spirit of English history was in contradiction to it. No later than the 13th Elizabeth, a statute had been passed, declaring it treason to maintain in any wise that the king and parliament had not the power to limit the succession. It was natural to lament that the feeling of feudal attachment was decayed. But the doctrine of a divine hereditary patriarchal right was a strange invention to replace it withal. The cavalier loyalty of Ormond belonged to former days, and had nothing in common with the superstition of Mainwaring and Sancroft. Principles utterly inconsistent with all that had been ever written on the subject, almost with all which had been ever done, became the favourite and insulting theme of speeches, proclamations, sermons. Thence the dread of the convocation sitting after the dissolution of parliament; thence the unanimous resolution that their new canons would not bind even the clergy; thence the protests against the new pulpit law, to make the king more absolute than his predecessors. Roman Catholic ecclesiastics had put their hands to Magna Charta. The Oxford decree was the boast of the Church of England. The latter books of Hooker, on account of their heretical latitude, were to be made out to be fabrications; whilst Jeremy Taylor, the great ornament of his profession, pronounces that there are few cases of conscience in which a man may hope for half as much conviction as on passive obedience and non-resistance. Non-resistance was soon improved into absolute compliance. It became, in other words, the indefeasible legitimacy of modern days. These prodigies of doctrine defeated themselves. They misled the governors and provoked the governed, and, in James the Second's expostulation with the seven bishops, returned

[1] "At the opening of parliament, the king very frankly delivered himself to the lords and commons, and was resolved to follow their advice in repairing the grievances at home, which he confessed the necessities of the times had brought upon his people. All those, whether in church or state, he was willing should be removed, and desired that all things might be reduced to the good order and practice of Queen Elizabeth; which to the people of England were sure looked upon with the greatest reverence." (1. Clarendon, 519.) This important passage is printed for the first time in the last edition. It is one of the worst omissions in the former garbled text. The speech is imperfectly given in the parliamentary history, with a rather later date. It is in itself a complete answer to the comparison laboured by Hume. The truth is, that the Stuarts had a dread of English history, for its testimony against them. Bishop Nicholson observes, in his *Historical Library*, that the publication of the second part of the Glossary of even the orthodox Spelman was supposed to be delayed, because he had called Magna Charta, *Libertatum Anglicarum diploma et sacra anchora;* and that in 1614 the Society of Antiquaries was suppressed on account of the jealousy manifested by James I.

them their poisoned chalice to their own lips. A limited monarchy and unconditional allegiance are a contradiction in terms. The only consequence of allowing to a brave and thinking people rights and privileges in the statute-book, and yet closing up every practicable channel through which, if they are violated, a legal remedy can be obtained, is the generating a spirit which sooner or later must force itself a way by some great convulsion. Another revolution, and the example of a new dynasty, were made necessary to establish the truth of the opinion which Gourville expressed in vain to Charles II.: "A king of England who will be the man of his people, is the greatest king in the world; but if he would be any thing more, he is nothing at all." So evident, indeed, has it ever been since the Revolution, that no king can long carry on the government upon any other terms than by becoming the man of his people, as represented in parliament, that the royal legislative negative has fallen into abeyance for a century and a half. Elizabeth, at the close of one session, rejected forty-eight bills which had passed both houses. The last exercise of this prerogative was in 1692, when William III. refused his assent to the bill for triennial parliaments. With the modifications, and under the circumstances in which alone the negative of the president of the United States can be interposed, it is easy to see how the head of that republic may prudently venture on the exercise of a power to which it would be the height of imprudence in a king of England so far to put himself in opposition to both houses as to revert. It cannot be said that the change is in the mode of operation only, and that the king does now by influence what he used to do by prerogative. It is notorious that, on several occasions since 1692, influence has failed in doing that which the acknowledged prerogative would have done by its single word. The result is, that the king, who for many centuries was more powerful in fact than in law, is more powerful in law than in fact at the present time.

If under the same forms the rise of the commons has changed imperceptibly, but entirely, their relative position with regard to the crown, this has happened to a still greater extent between them and the barons. The power of the nobility consisted in their immense possessions, in the clan-devotion of their dependents, in their territorial jurisdictions, and in the original superintending authority of the supreme feudal court. The blow struck at their properties, both by force and artifice, speedily took effect. The shake once given was so certain of spreading further, that the formation of new aristocratical fortunes out of the monastic confiscations has never been made an imputation on the policy of Henry VIII. It was as the favourite of Elizabeth more than as the lord of Kenilworth, that Leicester succeeded in making the gentry of Warwickshire wear his livery. The original relation between lord and tenant implied protection on the one hand, and obedience on the other. If the tenant could not alien without the lord's license, the lord could not transfer the tenant's seignorial dependence without the consent of the tenant. The social movement, commencing at the top, naturally occasioned a relaxation in these duties and sympathies on the part of the lord in the first instance. This broke the charm. It soon became evident that king-maker could be the title of no future Warwick. There had been a series of concentric circles, through which the feudal feeling rose from the vassal of the mesne lord up even to the throne. But all gave way at once. It was clear that the mischievous distinction between a king *de facto* and a king *de jure* could not be recalled, nor the allegiance of the subject transferred from the regal office of the sovereign to his natural person and blood royal, when once the feudal feeling lower down the ladder had been so completely destroyed, that, in the words of the age of Selden, an English tenant would be the first person to lay his landlord by the heels. The landlords and the sovereign have been both amply indemnified in increased security, for whatever either may have lost. At the same time the constitution and the country have been infinite gainers by the general adoption of a more rational patriotism. The civil exemptions which the peers possessed in their individual character were all along insignificant. The judicial authority vested in their territorial jurisdictions was superseded by circuit judges, and by justices of the peace in every county. That which had been reserved to them collectively was of a kind more honorary than formidable, and one which there was little temptation to abuse. The small value which they attached to their power as a civil tribunal is proved by the intermission which took place of all writs of error to the lords from the time of Henry IV. till the accession of James I. Their criminal jurisdiction, except in the case of impeachment, was confined to the members of their own order. From the time that the commons were united with the lords, and their joint assent became equally indispensable to all legislative measures, the sole undivided glory of Bracton's baronial court was at an end. A statute of Edward II. declares that every legislative measure not sanctioned by the consent of king, lords, and commons, shall be void. It states also that this is according to custom. Nevertheless it was long before the commons had the courage to act upon this supposed equality. Sometimes they stultified themselves by way of policy, to avoid any possible responsibility. On ordinary occasions they felt themselves overshadowed by the neighbouring greatness of the lords. Thus they applied to them on great emergencies, begging that they would send some of their members to instruct them in their duty (as in 1st Richard II.), "on account of the arduousness of their charge, and the feebleness of their own power and understanding." In the same manner, on the insanity of Henry VI. they left the establishment of the regency with the peerage. "You, the peerage, in whom, by occasion of the infirmity, resteth the exercise of his authority." In the reign of Charles I. the commons are seen for the first time taking the lead, and carrying the lords along with them. Several of the lords in that crisis gave in their adhesion, and co-operated with the commons. Before this, the spectacle of their concurrence had always been, the commons walking in the train of the lords. New principles must accompany such a change. The House of Peers could no longer claim the privilege of legislating exclusively for the benefit of their order, nor proceed on the distinction that they sit in their own right, answerable only to themselves; whereas the House of Commons, as a representative body, is answerable to the people. The sophistical distinction can hardly serve at present to prop up the privilege of their proxy; a pretension not less incompatible than popular instructions with the first duty of a deliberative assembly. Fifty years ago, when Paley first published his Moral Philosophy, the peers had so far fallen into the back ground, and political reasoners had so far learned to look to reason only, that Paley defends the institution of a House of Lords as a part of the British constitution, on grounds which would have amazed Simon de Montfort, and perhaps somewhat scandalized John earl of Somers. His main argument is founded on the use of a second and totally distinct legislative assembly, in order to protect the state against popular caprice and fury. Ever since the Revolution, the *momentum* in English legislation has lain necessarily in the commons. The king and the lords have both sought to keep there a hold, by way of influence, so as to fight their

battle in that field always in the first instance, and thus procure an additional guard against the chances of more direct collision. The reform bill has to a certain degree stopped up the communications by which this arrangement had been in substance effected ever since, and, in fact, long previously to, the Revolution. Mr Hume remarks, on the existence of two legislative assemblies, separate from each other, yet each of them supreme, as one of the great anomalies of the Roman institutions. The characteristic danger of such a state of things exists also wherever the consent of two or more men is required in carrying on public business. The only difference is, that the danger in the latter case is often counterbalanced by greater advantages; and that the mischief will probably be less violent from their opposition in the passive shape of refusing to legislate in the same direction, than in the more active shape which their opposition might have assumed in Rome, that of positively legislating, one against another. It is evident, however, that a society, the elements of which, by the supposition, are not paralysed and torpid, must soon find out the means of evading the evils of a political stale-mate. The necessary unanimity can be only obtained by reciprocal compromises and forbearance. If we will have the benefits peculiar to such institutions, we must be content to pay the price. In the administration of justice, the limits which separate pertinacity and weakness is one of the difficult discretionary questions which judges and jurors have to settle with their respective colleagues. If every member of a jury or a senate were to be as impracticable as Cato is described to have been, institutions of this nature could in no country be allowed to last a week.

Mr Hume and Mr Bentham appear to agree in thinking, that in the case of numerous assemblies called upon to determine the much more extensive and variable questions which arise in the general conduct of political affairs, it would be unwise to rely upon the exercise of a similar discretion, as sufficient security for the analogous compromises which are nevertheless indispensable conditions to an efficient co-operation. For this purpose they both acknowledge the propriety of some species of influence, which shall make the one to a certain degree dependent upon the other. In such a case the only question which remains practically to be argued will be its nature and the mode and degree of its exercise. If Dr Paley gives too much countenance to influences approaching to a sordid bias, Mr Hallam, it may be feared, is somewhat too confident in the assurance that moral influences will of themselves always secure a just, or at least an adequate, concurrence.

Polybius has shown that the simple forms of government, however suited originally to this or that stage of society, necessarily become in time unsuitable. What he describes as the specific germ of decay, "congenite in each form," would be more properly described as an alteration in society itself. This alteration drags the government after it into the requisite modifications of its form. It is one of the great merits of a mixed government, that, without the violence of a revolution, it can accommodate itself to these changes in a community, and pass the initiative with comparative facility from one class to another, just as the leading shoot in society may happen to be making head. Under a nominal invariableness in the balance, some variance in the weights must always be going on. The crown was not easily content to resign the ascendency it once enjoyed. When the higher classes had to outward appearance ceded the political powers they had formerly possessed, they were enabled afterwards by circumstances to continue in the covert enjoyment of it, to a much greater extent and a much longer period than any one could beforehand have presumed. James I. probably was not aware of the tendency of the proclamation by which, on calling his first parliament, he directed the sheriffs to address the writs upon a principle substantially the same as the late reform bill. There can be no greater proof, on one hand, of the respect of the people of England for ancient forms, and, on the other, of the moderation by which the higher conciliated the jealousy of the middle classes, than the fact that the adoption of this principle was postponed during the next two hundred years. In those classes, including the gentry and independent commonalty of the realm, in whom for some time past the heart's blood of the country has mainly been formed, the reform bill has at last placed the command of the House of Commons. The power which this portion of the community before exercised indirectly over the whole parliament, and especially over that house, it now exercises directly. The consequence is, that there is a much greater security than before, that no measure detrimental to their interests, and in opposition to their feelings, will be agreed to by a House of Commons of which they are themselves now made the constituents. There need be no fear for the duration of moral frame-works like that of government, on the ground of their supposed analogy to the growth and decay of material forms. There seems also no better foundation for the inference drawn by Polybius, in his comparison between the governments of Carthage and of Rome as they existed at the time of the campaigns of Hannibal, where he says that a mixed government, in which the preponderance has passed from the monarchical and aristocratical to its popular members, has run its course, and is so much nearer to its termination. Difficulties enough remain inherent in the nature of all government, which no possible adjustment of the machinery can reach. But a mixed, though incomparably safer than a simple, government, has some difficulties peculiarly its own. It depends on a nicer balance of proportions, and it calls for a greater degree of temper, patience, and mutual concession from its members. A rational and public-spirited House of Commons must be in constant danger of offending one or other of the extreme parties in the state. Whilst its honest concurrence with the other branches of parliament must frequently incur the displeasure of the demagogue and his mob, the sovereign or the peerage, one or both, are often not unlikely to regard its general or particular opinions with equal jealousy. A constitution thus settled is only safe as long as the more intelligent part of society can take advantage of its intermediate position, and arbitrate between the extremes. A House of Commons, identified with the great arteries of the nation, contains within itself no inherent security for good government, beyond the power of stopping bad measures, and of sending good ones up for their acceptance to the other partners in the firm. If they accept, well; if they reject, a class of cases arises, on which all the good sense and good humour of a country may be wanted, in order to guide a people to discriminate aright on the course which it becomes them to pursue. Unless a power of rejection, according to a liberal construction of independent judgment, be conceded, the whole benefit of a second assembly will be altogether lost. The power of rejection may, however, be so exercised by a headstrong monarch or by a small hereditary body, especially when, in the case of the latter body, the greater part of the legislature have been recently raised to the peerage from the ranks of one political party only, as to amount to a declaration that they are looking only to themselves, their own interests and passions. A civil disseverance from the sympathies of the nation, like that of the Roman Catholic clergy, justifies the extreme remedy of removing the obstacle by whatever

Government and Laws.

means. The occurrence of such fatal obstinacy in the person of the sovereign, would be an exception to every presumption upon which hereditary monarchy is engrafted on a mixed government. The contingency of so remote and so insane a possibility could only be formally counteracted by some such expedient as is adopted with respect to the veto of the president of the United States. In the instance of a refractory House of Peers, the constitution has given the king the means of applying this remedy by a creation of additional peers. This course was taken by Queen Anne on a much more questionable occasion, namely, for the sake of a mere ministerial majority. It is not the less clear that a justifiable occasion might occur. If the king took courage to apply the constitutional remedy, all would proceed as usual. If he shrunk from it, the public would be remitted to those ultimate considerations of civil prudence which are always in reserve. They are the very same considerations which justify the sacrifices of natural liberty which men must make upon entering into a commonwealth. They may equally justify the sacrifice of social order which man is called upon to make whenever a commonwealth is overturned. It is to higher authorities than the precedents which are to be found in Rushworth, that freemen have recourse when they are compelled to seek new modes of legislation by forms which announce that the constitution has been destroyed.

The spirit and effect of institutions and of measures depend, as has been shown, in a great degree upon circumstances beyond themselves. The same institution at different periods produces very different results, whilst the collateral and unforeseen consequences of a measure are frequently much more considerable than the objects which its framers had in view. All that is most important in the present forms of the English constitution, is of a certainty to be traced, however obscurely and imperfectly, from a very early date. At the same time, it has become what it is, only by making the most of a series of fortunate contingencies. The English government may be advantageously compared with the Roman in its best characteristic, the tendency to progressive self-improvement. In the nature of the improvements there can be no comparison.

According to the process pursued, the substance has been in a course of much more extensive alteration than the forms. With regard to the latter, the change has chiefly consisted in removing partial impediments out of the way of certain movements, in strengthening particular springs to meet particular pressures, and in separating the several parts of the mechanism by more positive divisions, lest they should clash one with another. The manner in which the English clergy overreached themselves, by standing on their claim to exemption from temporal jurisdiction, and on their right to be taxed for temporal purposes, if at all, by themselves only, and in an assembly of their own, is very instructive and curious. They chose to remain apart, a separate estate; and resisted the attempt of Edward I. to incorporate the inferior clergy in the House of Commons, when that house as yet existed mainly for taxation. They procured their convocation about the same time instead of it. Afterwards, in its palmy state of general legislation, they discovered, when it was too late, that their exemption was turned into an exclusion. In 1663 the supreme head of the church of England found it no longer necessary to keep up appearances with a body already but a shadow. Without a law, a struggle, or even a word, convocations have died away. The clergy, on submitting to taxation by a temporal assembly, have acquired in return the humble privilege of voting for the members of a house in which they cannot sit. A few bishops in the upper house are all that remains in the English institutions, of that third estate which was so necessary a part of the diets and states-general of the continent, and which made so great a figure in our own original constitution. The suspension of the royal negative, and of ecclesiastical convocations, has, almost unobserved, become part of the modern English system. Yet the change which has been thus operated is far more important, though it is short of what it is sometimes represented, than many which have been the subject of fierce contentions, and introduced by the most deliberate enactments.

Legislature.

The transitions which we have hitherto been considering, are independent of and paramount to legislation. They follow slowly but necessarily the variations in the condition of society and in public opinion, which must decide nine tenths of the materials and spirit of every government. We proceed, therefore, to consider the principal alterations which positive legislation has successively effected in the three great divisions of political power.

The main objects of a government have been mentioned as being the making, interpreting, and executing the law; the first being the office of the legislature, the second that of the courts of justice, the third that of the executive administration. It will be proper to examine each shortly in detail, both as to its duties and its form. The English legislature, acting together as king, lords, and commons, is vastly too cumbersome to take upon itself the detail of the executive. This union, therefore, has never been thought of. Its incompetency either as a whole or in its parts to discharge judicial duties is not so soon perceived; consequently bills of attainder, of pains and penalties, and impeachments, are part of the legal history of the most recent times. In the infancy of courts of justice, and when the traditional supremacy of the *aula regis*, out of which both they and the legislature had emanated, was yet an active historical recollection, parliament in all extraordinary cases continued to claim an original judicial authority. But this pretension gradually dropped, and the appellate jurisdiction is now evidently near its close. Regarding the legislature in its legislative capacity only, it will be seen that its form has remained the same as a whole since the first admission of representatives from the commons. The changes which have taken place have been confined to the construction of its constituent parts, and to the view taken of the characteristic rights peculiar to each.

In considering the several members of the legislature, the king takes constitutionally the precedence. Nothing can be more superficial and incorrect than the view presented by Blackstone of early English history upon this part of the subject. It was not until the accession of Edward I. that the several titles of election, descent, and testament, on which the claims to the crown were before rested, as best served the occasion, became consolidated in that of hereditary descent. This appears to have taken place in analogy to the descent of land. The rival pretensions of the houses of York and Lancaster tended to throw the law once more into confusion. Being principally tried and determined upon the field of battle, the law had too much the appearance of giving way to force, or to its hollow consequence, a mere ostensible election. Yet, even in those times, there was no notion that the crown was left at the personal disposal of the monarch. William the Conqueror, it is true, had set up a donation from Edward the Confessor. But Richard II. on giving his signet to the Duke of Lancaster, as testifying his wish that the latter might succeed him, added, "but that did not depend upon his pleasure." The lords, in a remarkable lecture to the protector, the Duke of Gloucester, whose powers under the will of Henry V. had been limited by

Govern- ment and Laws.

the parliament (for lords and commons are mentioned in the act), say his desire was grounded neither in precedent nor law; " the which the king that dead is, in his life, nor might by his last will, nor otherwise, alter without assent of the three estates, nor commit or grant to any person government or rule of this land longer than his life." The extraordinary provision of 28 Henry VIII. c. 7, is the first and only instance of putting the crown into settlement, with a remainder " to such persons as the king by letters patent, or last will and testament, should limit and appoint." It is plain that the testamentary power so granted to her father had puzzled men's minds in the time of Elizabeth; and that temporary authority to bequeath the crown has to answer for the strange and almost oriental scene by which the death-bed of that princess was disturbed. Since the Revolution, however, the parliamentary title is the one established in fact. Since the reign of Elizabeth it had been the only one recognised in law. The king never had a legislative initiative, but only a simple concurrence. The change of the form from petitions to bills, took away no right, but only an abusive advantage. The real legislative authority of the crown still continues in point of law the same that it has ever been. It was at no time more than at present, at no time less. The right to make law by proclamations, and the right to unmake it, whether by the repealing *dissimulavimus* of Edward III., or by a dispensing and suspending power, were always arbitrary usurpations. For these are utterly inconsistent with the principle, and almost with the letter, of the statute of Edward II., which had declared the assent of the lords and commons to be as necessary as that of the king; since the maxim that the same solemnity which bound is required also to unbind, is a rule of English law. The disuse of the royal negative since the reign of William III. is purely matter of discretion; however paramount the political necessity by which that discretion is determined.

The peerage was formed, under the feudal system, upon the principle of tenure, that is, of land held directly of the king; the mitigated sense in which the soil of the western world was understood to belong to the sovereign having been always very different from the absolute ownership of the sovereigns of the East. At the first, all tenants in chief had a right of summons to parliament, not yet known, however, by that name. During the period which elapsed between the demise of John, the last year of whose reign is remarkable for the division of the greater and lesser barons, and the middle of the reign of Richard II., when peers were first created by letters patent, tenure began to be disregarded. The political principle had so far got the better of the feudal, that in the 49th Edward III. the ancient writ of summons was changed from homage to ligeance. The further difference in the form of this appointment, as whether it was to be made by writ or patent, was of little consequence. But the dispensation from the necessity of holding land in chief was an important innovation. On the one hand, mere territorial possessions, distinct from descent, ceased to confer a title to a writ of summons; on the other, the writ in its general form might easily in time, by multiplying cases of dependent poverty, have turned this august assembly into the lacqueys of a court. It was well that a sense of dignity took the other course; though disfranchisements on account of poverty, as the act degrading the Duke of Bedford in the reign of Edward IV., and the resolution against Lord Ogle in the reign of Edward VI., were precedents liable to be abused. The questions, where the power of creating peers should be lodged, and the terms on which it should be exercised, were likely in early times to be determined by other circumstances than reason. The mode finally adopted, by which the power is intrusted to the sole discretion of the crown, appears to be, upon the whole, the most desirable. Yet the prerogative was so unsettled in practice, and probably also in law, that down to the reign of Henry VII. the assent of parliament was generally expressed in patents of personal creation. Upon this usage West founded his theory, in opposition to Prynne, that such assent was a necessary condition. Whatever may have been understood to be the law, the practice was liable to all the objections so triumphantly urged against the bill twice proposed by Lord Sunderland in the beginning of the last century, for limiting the number of the peerage. Whilst a restraint upon the royal prerogative of creating additional peers would occasion more evils than it could cure, no similar risk accompanies the withholding from the crown a power of punishing by exclusions or of privileging by exemptions the actual members of that body. Accordingly, Lord Coke holds that even dispensations, answering to the excuses formerly besought by poor boroughs, granted by the king in relief of lords petitioning to be spared the burdensome service of attendance, were contrary to law. The mode in which the prerogative of creation was exercised varied with the times, but never seems to have been felt to be a grievance. The jealousy of the Stuart creations before the breaking out of the civil wars, and the remonstrance against the Scotch and Irish honours, was only a temporary ebullition. The degradation which the decay of families might have brought upon so much of the peerage as was called by a general writ of summons, came to a certain degree within the control of two principles: the one, that a patent without words of inheritance is simply a dignity for life; and the other, that peers might be summoned only to a single parliament. There are instances of ninety-eight laymen who were summoned only once, of fifty others who were summoned two, three, or four times. The present course, however, of descendible nobility, is as old as the reign of Elizabeth. The uniformity of our modern usage would be corroborated, amongst other causes, by the contemporary extinction of a corresponding variation which had previously subsisted in the summons of the ecclesiastical members of the House of Lords. The bishops are said to sit by a usage compounded of a triple title. They are supposed to be the representatives of the church, to have been more learned counseilors than the lay nobility, and to be the life-proprietors of the baronies attached to their sees. The last condition, however, is wanting in the sees erected by Henry VIII. But parliamentary bishops formed a small portion of the spirituality in the upper house. Out of one hundred and twenty-two abbots and forty-one priors, who occasionally sat previously to the dissolution of the monasteries, it appears that only twenty-five abbots and two priors were constantly summoned. There are numerous instances of the allowance of exemptions to abbots and priors after summons, by reason of their holding nothing of the king. This ground of exemption, as insisted on and admitted, shows *whence* the duty was derived. It does not follow but that the grounds of *right* on their part might be more extensive. It is according to this distinction that the writ requiring the attendance of the temporal nobility by summons, belongs to a period and style when its duties were an *obligation*, and were recognised as such; the patent to a period when they had become an *honour*. The most important parliamentary change, however, which collaterally resulted from the dissolution of the monasteries, was the subordinate condition to which it reduced the church numerically in the House of Lords. This alteration was likely to diminish the general political influence of the church much more than the subsequent cesser of the convocation in 1663.

Government and Laws.

The authority of the convocation being confined to the clergy, the public at large had little immediate interest in its operations beyond the share which they might therein please to assess themselves by way of ecclesiastical contribution towards the public burdens. In point of fact, the temporalities even of the church seem to have lost nothing from either cause; much less its substantial influence. Few will think, whilst the clergy have been shut out from the lower house of parliament, and are now represented by thirty spiritual peers only, that their friends have not done for them behind their backs quite as much as they could have done for themselves if present. The influence of the church of England in its apparently almost unrepresented and unprotected state, is a great proof how little comparatively depends on the means by which an end is to be produced, when a power, composed of a wealth, an intelligence, and an opinion competent to produce the end, is really in existence out of doors. Although the dignitaries of the Roman Catholic church varied in numbers from time to time, yet they always formed the actual majority of the House of Lords up to the Reformation, which, nevertheless, they could not stop. Here, again, with what prudent reserve did the Roman Catholic clergy husband for ages the political power which mere numbers vested in their hands; and how evident is it that, whatever form, even of superstitious incarnation, the dominant spirit of a government may assume, it is only by compromises that it can subsist. The Stuarts, the great examples of every species of political misrule, would have been ruined by this alone; they were bent on acting up to the very extent and margin of their powers. Nobody reading English history previously to the Reformation would have an idea that during all that time the temporal nobility were in a minority; that therefore their legislative importance existed only by permission; and that every act of the House of Lords might be said to be in strictness the will and pleasure of the church.

The number of the lay nobility has fluctuated considerably. It had advanced from fifty-five in the reign of Henry VIII. to one hundred and six in that of James I. It is at present 420. The aristocratical complaint made by Lord Delamere under James II., that, ever since the time of Henry VII., a systematic project had been pursued to humble the peerage, by means of multiplying its numbers, and by introducing into it persons of mean extraction, was particularly injudicious. Unless something of this kind had taken place, the extreme disproportion between the two houses, in their external as well as in their personal titles to consideration, would have deprived the peerage of a great part of its present strength. If the order was to be more than a pageant, it became most desirable to increase its numbers to the extent of giving them a better chance of bearing some comparison in ability and character with the select representatives of the rest of the nation. It was scarcely less so to recruit into their ranks those members of the commonalty who, whatever might be the obscurity of their pedigree, were most distinguished for their wealth or services. Thus alone could the body have been protected against the narrow sense of corporate pretension which must otherwise have infected it. The long recollections which feudalism has left, and the recent jealousy which has collected around corporations, notwithstanding their former usefulness, demonstrate the depth of the national re-action, which all invidious exclusiveness unavoidably provokes. In fact, no amount of popular opinions has been sufficient to save the combination of the great Whig families from a suspicion of aristocratical tendencies of this description. The popular criticisms on the corn-law legislation of landed proprietors are a proof of the keenness which watches every supposed connection between public policy and partial interests. An evil not quite similar, but equally, indeed in all probability more, destructive in its consequences to the object and safety of the peerage as a branch of the legislature, must follow, whenever its vacancies are too long filled up from a particular party in the state. It is self-evident that the chances of a difference of opinion between a House of Lords partially constructed, and a popular House of Commons, cannot be raised with impunity beyond a certain point. Under the most accurately-balanced government, the question, whether the Lords shall at any time interpose their legislative negative, must of course, as in the case of the king, depend at last on their own discretion. The difference in practice is found in their respective positions. There can scarcely remain a possible presumption in favour of the single opinion of a chief hereditary magistrate, when a majority of the nation, aware of that opinion, is found constitutionally ranged against him. On the other hand, abuse in their original appointments, and ignorance of the duties and necessities of their station, must have gone to an extravagant length indeed before a body of the nature of the House of Lords is put in equal peril by the rejection of whatever measures may be sent up to it by a majority of the House of Commons. Take either extreme; a House of Lords in constant collision with the Commons, or a House of Lords only occupied in registering its edicts. In the former case, it cannot exist long; in the latter, it is already existing only in name.

The popular part of the English constitution is lodged in the House of Commons, which originated in the year 1295; and, in its present extension, consists of the representatives of different interests or sections of the community, by individuals of their choice. It is very singular that the simple expedient of popular representation, an indispensable condition to every form of a free government in a great kingdom, never occurred to the legislators of antiquity. By this device, the experiment of a free government is entirely changed, and becomes, under all circumstances, infinitely more practicable, safe, and beneficial. According to the ordinary theory of the English constitution, the House of Commons is said to represent the whole population, as far as it is supposed to be by its circumstances independent. Of these, the knights, or the members returned by the freeholders of the county, are alleged to represent the interest concerned in agriculture; whilst the citizens and burgesses, or the members returned by certain towns, have been described as representing the interest concerned in trade. The basis of English representation, at first very limited, and long extremely fluctuating, was never so extensive as to answer to the first part of this theory; and time rendered it, by the rise of some places and the fall of others, still less so. The reform bill has probably more nearly approximated towards realizing the theory of a representation as universal as the independence and intelligence of the people, at the present than at any former period. The most that can be said of the latter proposition is, that some such division as it assumes between real and personal property, agriculture and trade, probably appeared originally between the two classes of members. This was the natural course as long as the duty of the House of Commons was confined to taxation. The original demarcation would probably continue visible as long as parliamentary attendance was considered as a burden rather than an honour. Historically, this and any similar distinction gradually fell into disuse soon after the 23d Henry VI. That statute required the knights of the shire to be actual knights, or such notable esquires and gentlemen (*generosi a nativitate*) as had estates sufficient to be

Government and Laws.

knights, and by no means of the degree of yeomen. We find that a county member who had been actually elected, was set aside because he was not of gentle birth. A great change must be commencing before the possibility of the want of such a precaution could be suggested; and still more before the precaution, when taken, should not immediately succeed. The change may be assumed to have begun as far back as the 19th Edward II. when there were twenty-eight county members who appear not to have been knights. Of course the arrangements and very elements of society must have been still further broken up, before a manufacturer could have a chance of a successful nomination with the freeholders of a county court. It is but little that positive legislation upon these points either accelerates or retards. It can recall nothing; and, to be effectual, must continue to be in harmony with the wants and character of the times. This was abundantly proved in the failure of the statute of Henry V. the object of which was to compel members to be inhabitants of the places for which they served. The attempt fixes the era when the deviation from the old connection was attracting general attention. Its pertinacious vitality in the statute-book is a striking instance also of the extreme reluctance with which the English people, so far from anticipating needless innovations, have consented to affirm the innovations made by time itself. Prynne shows that Cornish names were formerly returned in the elections for Cornwall, and northern from the north. Clarendon opens his memoirs by stating the little communication which passed between different parts of the country, even with the metropolis, almost to his own time, except in the circuits of the lawyers. The names of the members for the counties were aristocratical, those for the boroughs plebeian. A few burgesses begin to be called esquires in the returns of Edward IV. By this time the House of Commons was becoming of sufficient importance to render parliamentary influence with a borough an object of ambition to the nobility and gentry of its neighbourhood. The character of the borough representation opened and extended itself accordingly. It soon embraced every description of person who had a claim to enter into public life. The lawyers, to whom attendance was probably less personally inconvenient than to others, appear to have come in earlier for more than their reasonable share. But this expansion and adaptation beyond its original purpose could alone have made the inequalities and anomalies of the borough representation tolerated so long. The citizens and burgesses, though always more numerous, seem to have felt their social inferiority, and for a long time to have continued more humble minded than the knights. Of the three hundred members, the average number from the 23d Edward I. to Henry VIII., a third or more were returned by the boroughs. During this long interval the sheriff exercised a discretion, to the use or frequently to the abuse of which the parliamentary existence, by prescription, of many unincorporated boroughs is to be ascribed. Boroughs by charter, even from mesne lords, and towns, whether the ancient or the actual demesne of the crown, made up the list. Many boroughs were originally inconsiderable places; and others imperceptibly decayed. This latter cause would take effect from the reign of Henry VIII., the date at which the elective franchise became constitutionally too valuable to be left, when it had been once enjoyed, to the mercy of the sheriff, or to be allowed by its possessors to drop into disuse. The royal prerogative of new creations which existed in the House of Lords, existed also over the borough compartment of the House of Commons. Elizabeth indulged herself in the plenary exercise of it in England, as freely as her successor did in Ireland; but, supposing that her subjects had ventured to remonstrate, she was too wise to have ventured, in return, on his indecent answer: "The more the merrier, the fewer the better cheer." The prerogative of adding to the boroughs, however, is one which could not last in an enlightened age. The same reasoning which pleads against a parliamentary or popular appointment of the peerage, presumes a parliamentary or popular appointment of the commons. It is not so surprising, that after the shaking up of the political opinions of the nation during the civil wars, one instance only of borough creation (that of Newark) should have occurred, as that Charles II. should have made the experiment even of one. Borough creations were the great reservoir whence the successive accessions to the numbers of the House of Commons had been supplied. Nevertheless, owing to the course pursued previously to the passing of the reform bill, the interests engaged in commerce and manufactures appear, notwithstanding the vast contemporary augmentation of their wealth, to have had less power in parliament, or at least less influence on legislation, than in an earlier age. The House of Commons in the first parliament of James I. consisted of 470 members. The last unreformed and the present reformed representation, reckoning the additions derived from the Scotch and Irish unions, are not much more numerous. They both give a total of 658. The difference between the two lies in the proportions in which these numbers are divided amongst the several classes of the people. It has been calculated that a hundred and fifty-four persons returned a majority of the former house. Counties formed the only large constituencies, whilst scarcely a single large town was represented. At present the franchise is compounded of a ratio of property and numbers. Mere nomination is destroyed; and, on analysing the numbers, it will be seen that the members for counties are 253, the members for towns and the universities 403. This question of proportion, though it has been assumed by critical writers, was evidently never before seriously thought of. The necessity of entering on such comparisons had not yet arrived. The means of securing the impartiality of the sheriff, and the independence of the electors, was formerly a more immediate and important point. It is impossible, from the gross partiality of the sheriffs (officers annually appointed by the crown), to reason upon the old returns. The freeholders of a county court were of course placed comparatively beyond their reach; yet sheriffs contrived to aid in the virtual disfranchisement even of counties. According to Prynne, it appears by the indentures that, as late as the 8th of Henry VI. the attorneys of a few great people could dictate or manage on occasion the representation of Yorkshire itself. In the meanwhile political information was spreading. Reformers of all kinds sallied forth. The decayed boroughs, and the consequent flagrant inequality of representation, became the subject of a criticism, founded on theories more or less correctly derived from the practice of earlier times. The very word representation provoked observation, and was in many instances in ridiculous contradiction with the fact. It appeared impossible that this could be what the constitution intended by the name. Even James I. was struck by it on his accession. The charge given by him to the sheriffs, on calling his first parliament, not to direct a writ to any ancient town, being so ruined that there were not such sufficient residents as to make a proper choice, comprehended a most desirable reform. The fault was in the mode which he proposed for carrying it into effect. The supposed prerogative was more than could be safely entrusted to a sheriff of James I. The system grew more unreasonable every day, both in reality and in appearance; and, to complete its indefensibleness, the stain of corruption gradually crept in, and

Government and Laws.

deepened the offensive spectacle into a scandal and a nuisance. The reform bill has at last brought this long outstanding grievance to a satisfactory conclusion. The elective basis is so enlarged as to comprehend all the elements of sound national self-government, and the independence of the electors is amply secured against all danger but from themselves. The interference of the executive in elections may be more immediately dangerous to freedom; but a constitution undermined by corruption is infinitely more disgraceful to the parties who are guilty of it, and to their fellow-countrymen, who sit still in stupid connivance at their baseness. Lord Coke, mentioning the first case of bribery on record (in the 13th Elizabeth), denounces it "as poisoning the very fountain itself." The disease was communicated slowly. It is not yet a hundred years since it had reached the height and notoriety of being a public evil and a national dishonour. Clarendon, in his disdainful notice of the first ministerial intrigue in order to buy over a majority by bargaining and not by reasoning, leads us back to the origin and cause of all. He fastens on the government the first link of the chain, the length and burden of which naturally increased at every remove. Bolingbroke, the distinguished father of the modern Tories, lays the principal blame of it on Clifford. Members who could make money of their own votes, found it was worth while to pay for the votes of their constituents. Evelyn's *Memoirs* contain frequent ejaculations on the increasing expense and debauchery of elections, before and after the Revolution. In works of the date of Brown's *Estimate* and Chesterfield's *Letters*, it is noticed, for the first time, that the franchise of making laws for the English people was disposed of by boroughmongers under private pecuniary contract, or brought openly to market by burgesses and freemen, for the competition of public sale. The expense of elections, to say nothing of bribery, had become so ruinous, even in the earlier days of Burke, that in a speech on one of Mr Sawbridge's motions, he says, "the expense of the last election has been computed (and I am persuaded that it has not been overrated) at L.1,500,000—three shillings in the pound more than the land tax."

The antiquarian question of the origin and progress of the House of Commons is interesting, not merely as the title-deeds to English freedom, but as constituting an important chapter in the history of man and of society. It describes the germ and development of an institution which, in its extensive and permanent application, is an invention of modern times, and the most likely of all, not even excepting the steam-engine and the press, to influence the fortunes of the human race. In this view, the great consideration is not so much the steps by which its component parts were formed, as those by which its authority was obtained. There can be no doubt that the early summons to the commons was not honorary, but onerous. Long after the general right was perceived to be a national advantage, the particular exercise of it was felt to be an individual hardship. The real history of almost every people is in its exchequer. This is emphatically the case with England. Fiscal considerations lie at the bottom of its most celebrated institutions and enactments. Every body worth taxing was to be got at in some form or other. The right of arbitrary tallage upon towns was limited and invidious. It was abolished in the 25th Edward I. by the time that the new experiment was coming fairly into play. In the facilities which representation afforded to taxation, government soon found a compensation for the slight additional control and inconvenience which the co-optation of the commons into the legislature might by degrees and at times occasion. The yeomen owners of freehold lands were to give an account of their pecuniary capabilities in that character. Wherever property had grown up in other shapes, as in towns, it was also to be made amenable. Apparently when this was done by way of deputies, which was the ordinary mode in the estates and diets of the middle ages, no particular directions issued. There is not a word said in the writs concerning the qualifications of the electors, or the numbers to be elected, or the forms to be observed, either in counties or in boroughs. Two was the number fixed upon, probably to prevent subsequent confusion, either by prevarication, mistake, or sickness; and usage would soon turn the practice into law. Whilst taxation was the great object at stake, it was one in which all might equally be trusted for labouring to reduce the subsidy to the lowest point. The franchise in boroughs would easily devolve from the towns' people at large to a select council, when all that the voter got by insisting on the privilege, was a liability to pay his share towards the parliamentary wages of the member. The election struggles of a later age, indeed ever since the committee of which Serjeant Glanville was the chairman, have been vain efforts to undo the effect of these irregularities and encroachments. But the great objects of a national legislation and the spirit of freedom were of older date. Long before the actual existence of the commons as a third estate in parliament, the barons had extorted from their monarch, and had transcribed into the rude articles of Magna Charta, a principle and a feeling, before which the traditional longings after the laws of Edward the Confessor speedily expired. There was little left for the patriots of after times to add, but the necessary machinery of more adequate forms and institutions. Magna Charta seems to have been looked upon almost as a personal contract, which it was necessary to renew at the commencement of every reign, in order to make it binding upon successive sovereigns. The terms of its successive confirmations (Lord Coke reckons no less than thirty-two) fixed in the minds of men an inseparable connection between the grant of supplies and the redress of grievances. The House of Commons put forth at different periods the claim to its peculiar privileges and its general powers. As early as the reigns of Richard II. and Henry VI., we find it refusing to proceed in the public business without a sufficient answer. For a time the two houses voted separate and unequal aids. The first notice of the maxim that parliamentary aids must be granted by the commons and agreed to by the lords, appears in the 9th Henry IV. As the report expresses it, when both are of accord, the grant is to be signified to the king by the mouth of the speaker of the House of Commons. This is said to be "in manner and form accustomed, to the end that the lords and commons may have what they desire of the king." The strictness of this privilege can never have stood on any sufficient reason. It was unimportant whilst the two houses voted their subsidies singly, and bound each other to different amounts, which continued to be the course with the clergy in convocation to the last. It was still more indifferent which of the two began from the time that supplies were voted by them in concurrence, since either house, by the use of its negative, could protect itself. Restraints on the initiative are not worth contending for. The exclusive right of determining all questions connected with the elective franchise would have been a more equitable distinction. Upwards of a quarter of a century before the third estate was called to parliament, the barons had paid the subsidy demanded of them into the hands of four of their own order, with directions to expend it at their discretion for the benefit of the king and kingdom. It was not until after the Restoration that the House of Commons was provoked, by the scandals of the court of Charles II. to adopt the much more respectful form in use at present, for the control and appropria-

tion of the national expenditure, although Clarendon declaims against it as an unheard of innovation. Of all their civil rights, immunity from taxation, except through parliament, has been that of which the English people were most tender, and which they first succeeded in thoroughly and irrevocably establishing. After the reign of Edward III. a few attempts, ill concealed under the soft words of loans and benevolences, are slight exceptions to the universal current of precedents. On this, admitted by Clarendon to be the clearest of all points, the Stuarts dragged the judges with them into the abyss. The patience and perseverance of the English people are equally signalized in the steady parliamentary resistance by which the account of ages was closed with the act of the 16th Charles I. c. 8, against the imposition of tonnage and poundage, without consent of parliament. It is the last act in the statute-book against arbitrary exactions of revenue. The right to participate equally in general legislation was obtained early, but slowly enforced. The 15th Edward II. had recognised the necessity of the concurrence of the commons to all measures whatever in the most positive terms. It is probable, however, that for some time afterwards, its assent for all purposes except taxation was little more than constructive. The commons, it is true, after the next reign, figure, by name at least, almost always in the enacting clauses; the laws being generally said to be made by the king, with the assent of the lords, at their request. At this period, however, the king, by diminutions and additions to a petition, often so completely changed its nature, as to become himself the real legislator on its contents. They consequently insisted, in the 2d Henry V. "considering they had ever been as well assenters as petitioners," that without their assent it should be no statute. The abuse was only put an end to in the reign of Henry VI. by the slight variation of drawing up the bills in their present form. There is only one instance mentioned during the tyranny of Henry VIII. of the rejection of a bill supported by the crown. The commons found courage on several occasions to resist the measures of his children. The year 9 Henry IV. above referred to, is also remarkable for the first assertion in behalf of freedom of speech in parliament, by declaring that the king is to take no notice of what passes there. This impunity is confined, however, to the locality of the speech so spoken. A publication of it by the press or otherwise is responsible to the ordinary law. The earliest definition of privilege on arrest is in Larke's case, in 8 Henry VI. The case of Storie in the 4th Edward VI. is the first commitment which has been recorded of one of their own body for contempt. In proportion as the House of Commons became gradually more and more mixed up with the general affairs of state, the possession of these powers and privileges rose in importance, as being essential to its independence. Mere assurances of this or that immunity are of no avail, unless the means of realizing them also exist. The necessity to which Sir Thomas More was obliged to yield, of retiring into private life, in order to escape the displeasure of Henry VII., on account of a speech in the House of Commons, shows that the season for a valid parliamentary opposition had not yet arrived. In the attack upon the five members in the house itself, Charles I. outheroded himself. On other occasions, he had lain in wait for the dissolution of parliament, which was his usual signal for resuming more open hostilities against the liberties of his people. As soon as the speaker's mace had been disenchanted of its protecting power, the royal warrant was wont to go forth against the most popular of the late members by whom his illegal designs had been principally thwarted. The law and the fact, however, improved together. Both houses have long been in possession of whatever powers can be necessary for the performance of their public duties. Popular members are as safe after as during sessions. Nobody dreams of intimidation. Parliamentary corruption has not merely declined; it has almost disappeared. If a comparison between the pensioners and placemen of ancient parliaments, with the modest list of officers of the crown sitting there at present, be satisfactory, what ought to be felt at the contrast between the unblushing bribery of Walpole's administration and the purity of modern governments? The compulsory economy introduced into the treasury has co-operated, with other causes, of which the chief is public opinion raised under the sanction of the middle classes, to elevate the standard of public morals amongst public men. The boundary which separates legitimate and undue influence, is that at which practical politicians no less than theoretical reasoners have arrived at last. As corruption began at the top, it has first ceased there. Whatever remained to be done in improving the public spirit of the elected, as well as of the electors, it is the direct tendency of the reform bill to accomplish. The elective franchise is now thoroughly identified with the nation, and is made, in the eyes both of those who choose and those who are chosen, more visibly and entirely a public trust. The destruction of the nomination boroughs leaves no pretence for the open constituencies which persevere in converting the trust into a sordid personal advantage. The parts which unfortunately appear to continue tainted are as yet inconsiderable. Unless they yield to the alteratives by which the whole body politic has been renewed and strengthened, they must be cut out. History holds out no hope that the inconsistency of incorrupt representatives and of corrupt electors can continue long.

The supposition of a legislature consisting of three coordinate authorities, does not imply a defined line or logical division to which they must each conform, and which every body can distinguish; on one side of which, the concurrence of the several parts must degenerate into mere dependence; whilst, on the other, their separation must form into impracticable opposition. The experience, however, of all mixed governments, more especially a comparison of the case of England with that of countries subject to the simple forms, establishes the fact that it is not a mere fiction, concealing under nominal distinctions the real servility of the inferior in their subjection to the superior members of the supposed partnership. It is evident that a sort of adjustment does practically take place, sufficient to produce a palpable effect. The nature and temper of a particular society may easily make such a constitution impracticable. But, under fortunate circumstances, it in a great measure accomplishes the ends which it is its professed object to perform. The problem assumes the natural inclination of its respective parts to press unduly on each other. In tracing a constitution which has been formed by time, and has endured through ages, the tendency of the several biases must be expected to be more apparent, now one way, now another, than in a government of entirely new construction. Encroachments at different periods are more likely to take place, from a recurrence to former usages on one side, or from a spirit of re-action to them on the other, in constitutions which have grown up, like those of England and ancient Rome, by the amendments of centuries, than in mechanical contrivances, like the government of Lycurgus and that of America, modelled from the beginning and at once, on an express design. Accordingly, English history presents examples of each branch of the legislature in its turn assuming a legislative power. The king has issued his proclamations to create, not to promulgate law, under the pretence of state expediency. An irregular exercise of the equivalent power of suspending or dispensing with the law, in other words, a claim to

Government and Laws.

untie by himself the knot which the entire legislature had tied, had prevailed so long, that even at the Revolution it was only partially denounced. Ordinances authorized by both houses, whether for the militia or otherwise, are equally indefensible. The same is the case *a fortiori* with resolutions by either house singly against putting in execution such laws as happen to be unacceptable to it, but which the other branches of the legislature are not willing to repeal. Notwithstanding a most unguarded admission by Mr Justice Gould to the contrary, in the conflicting decisions which arose out of Wilkes's case, there can be no doubt but that the doctrine of Lord Mansfield is correct. Speaking of declarations of law made by either house of parliament, he observed, that he never thought himself bound in his judicial capacity to honour them with the least regard. The vote of the commons in 1648, that their single enactment was law, called forth on the Restoration the statute of 13 Charles II. It subjects to the penalties of *præmunire*, the advised affirmation that both or either of the houses of parliament have any legislative authority without the king. The unconstitutional attempts of both houses, especially of the lords, to extend their jurisdiction as courts of justice, brings us properly to the next consideration.

Judicial power.

The necessity of separating the judicial from both the legislative and the executive power, and of vesting it in independent tribunals, is now universally admitted. But it is a necessity which antiquity never perceived; and it was in direct opposition to the letter and the spirit of the feudal system. Therefore the successive generations which moulded the English constitution into shape, may be excused for having learned it but slowly and by experience. English history providentially is stained with fewer judicial iniquities, which are the greatest of all crimes, than that of almost any other country. But a failure of justice is the worst feature of the long period comprehended in the lines of Plantagenet and Tudor. Perhaps the greater part of the deficiency is to be attributed to the imperfect division of these powers, especially of the executive and judicial. Lord Clarendon has left a picture, sketched as late as the middle of the reign of Charles I., of what may be expected from a legislature, a court of justice, and a board of administration, all in one. Officers of the crown became "a court of law to determine civil right, and a court of revenue to enrich the treasury; the council table by proclamations enjoining to the people that which was not enjoined by the laws, and prohibiting that which was not prohibited; and the star-chamber, which consisted of the same persons in different rooms, censuring the breach and disobedience of those proclamations by very great fines, imprisonments, and corporal severities; so that any disrespect to any acts of state, or to the persons of statesmen, was in no time more penal, and the foundations of right never more in danger to be destroyed." The supreme courts at Westminster were originally derived out of the royal court or *aula regis*, which consisted of the great household or personal officers and the barons. They were intended to dispatch the ordinary judicial business, especially during the absence of the household and personal officers in attendance on the king, or when the barony might not be assembled. The authority of these derivative courts, whatever might be the case with the *aula regis* as far as concerned the barons, was not in the eye of the law inherent. It was supposed to be delegated to them by the king, as the fountain of justice to his subjects. The judicial power of parliament, however, was not displaced, nor meant to be so, by these auxiliary institutions. Fleta, writing in the reign of Edward I. treats it as still the high court of justice, "where doubtful cases of judgments are resolved." There can be no doubt but that annual parliaments were first demanded, and their intermission felt to be a much more serious grievance on account of their judicial than of their legislative capacity. It is evident, from the state of the early statute-book, that the meeting of many a parliament might have been saved had they met only for the purpose of legislation. There is a memorable order of 18 Edward I., by which petitioners to parliament are apportioned to the several subordinate courts of justice, both for their own dispatch, and to enable parliament to attend to public business. If the matter happened to be so great or of such grace that these courts could not end it, the chancellor and chief ministers were with their own hands to bring it before the king and his council. Coke observes, that wherever the king and council are mentioned judicially, it is to be interpreted to mean the House of Lords. The celebrated treason statute, 25 Edward III. closes its enumeration of the treasons specified therein with the express reservation of "other like cases of treason which may happen in time to come." In which case "the judge shall tarry without going to judgment of the treason till the cause be showed and declared before the king and his parliament, whether it ought to be judged treason or other felony." The reservation, however inconsistent with the right of a people that the law shall be defined beforehand, so that they may know what to avoid, and under what penalties, is plainly a reservation of judicial and not of legislative power. In fact, this parliamentary superintendence is recorded, on the authority of Chief Justice Thorpe, to have been at that time the common course in other cases as well as treason. He stated, in the 40th Edward III. "that he and Sir Hugh Green went together to the parliament, when there were present at least twenty-four bishops and earls, and asked the opinion of those who had been the makers of the late statute of jeofail, concerning the alteration of a record." "At another time," the same judge says, "we were commanded by the council, that when any case of doubt should happen, we should not go to judgment without good advice; therefore," adds he, in the case then before the court, "go to the parliament, and as they will have us do we will, otherwise not." The danger from this anomalous tribunal would have been increased a thousand fold, if the lords had succeeded in the unwarrantable claim which they set up in 11 Richard II. to a law of parliament differing from the civil and the common law. The extension of this irregular claim by Coke to the privileges of the lower house was more, certainly, than the imperious barons of Richard II. ever contemplated by their mutinous declaration. But it is still more unwarrantable, and more surprising, that Burke should have renewed the doctrine of a parliamentary supremacy, in judicial proceedings before parliament, over the rules of ordinary law. As the penalty of this grievous error, his admirable Report on the proceedings against Warren Hastings remains comparatively unknown.

The share which the House of Commons took in this judicial jurisdiction was, if any, very inconsiderable. Thorpe in the above passage uses the word parliament, but mentions only earls and barons. The ordinance 6 Henry IV., which has provoked so much legal spleen, from its directing that no apprentice or other man of the law should be elected a knight of the shire, took its hint from a previous one in the reign of Edward III. against lawyers practising in the king's court. They were accused of putting forward, as public petitions of the commons, matters which concerned only their own clients. Notwithstanding the expression client, the ground of disqualification here assigned relates probably to what was formally legislative, and not judicial business, something like the private bills of the present day From the course of the constitution,

as well as on their own disclaimer, Mr Hallam considers that the intermeddling at all in judicature by the commons upon the petitions addressed to them, was pure usurpation. He suggests that their intrusion may probably account for the disuse into which, from the time of Henry IV. the lords allowed their appellate authority to fall. It is very difficult to make out the steps by which they could have claimed the right in question. But there is some difficulty in conceiving that the influence of the House of Commons was so commanding at the period in question as the alternative supposition would imply. Could they be strong enough to make good a mere encroachment of this sort, and leave a competitor like the House of Lords no other method of resisting their invasion of its ancient right than by also abandoning it altogether? Writs of error were resumed by the lords about the accession of James I., renouncing all claim to any original jurisdiction in judicial causes. This is surely anomaly enough. All pretence for the other had disappeared in the equality of persons, in the uniform supremacy of the law, and in the acknowledged excellence of the ordinary tribunals. Notwithstanding this disclaimer, the extent to which the English legislature, under circumstances more or less excusable, perplexes itself with questions properly belonging to courts of justice, is subject to serious objections. It nowhere appears to such disadvantage as in bills of attainder, of pains and penalties, and divorce bills, which are all proceedings of a judicial nature applied to a case of *ex post facto* law. In judicial inquiries, carried on as such by either house, its numbers, partialities, habits, and the intrinsic difference between legislative and judicial considerations, make it impossible to convert a legislative assembly into a satisfactory court of justice. This truth has been frequently, and is still, occasionally verified. In its character of a court of ultimate appeal, the House of Lords escapes the disgrace which must otherwise have been heaped upon it long ago, by retaining the jurisdiction only in name, whilst the jurisdiction is in fact abandoned to its legal members. There is more to be said for so peculiar an exception as that of an impeachment. But later precedents, as in the instance of Warren Hastings and Lord Melville, do not warrant the expectation that an impeachment, even before such a body, can easily become an efficient instrument of justice. The only judicial matters which can be brought before the House of Commons are proceedings for contempts. Hurried on under great excitement before the whole house, they are exposed in an aggravated shape to whatever risk proverbially disqualifies an individual from being a judge in his own cause. It is only in comparison with what is recorded of the trial of disputed elections by the house itself, that election committees have acquired a conditional reputation. Committees on private bills are frequently legislative only in form, whilst they are in reality judicial inquests. They consider themselves above even the forms of justice. Nothing is more common than for members to oblige their friends, by stepping in to divide upon the merits of a case, where they have never heard a syllable of either the evidence or the discussion. It is a singular instance of the force of habit, and of the barrier raised by technical distinctions, that this is done by persons who would act nevertheless with perfect honour upon a jury.

In a simple state of society the judicial and executive authorities are always found united. Eastern kings administered justice at the gate; St Louis under the oak. A confusion between these authorities is therefore, under all governments, in the natural course of things a more probable event. The original theory of the English constitution, as far as theory can be predicated of its rude provisions, saw no incongruity between the duties. The traces of an entirely opposite presumption are still amongst the minor embarrassments of at least the language of the law. The administration of justice in the name of the king was formerly more than an honorary prerogative. It was a feudal truth and necessity. It is now a fiction which can only mislead both kings and people. Blackstone says, that when the law calls the king the fountain of justice, it does not mean that he is the author of it, but the distributor. Yet there are many things contrary to this distinction, and the contradictions show most strongly the mischief of these metaphorical compliments. The payment of fees on original writs, the unjust rules in the exchequer in behalf of the prerogative, the flagrant fines in the olden time as the only means of obtaining common justice, presuppose that the king was so far its author that he could only be asked to grant it upon his own terms. Judicial extortions became less frequent after Magna Charta; but they prove the grievous necessity which existed for its assurance that the subject should have remedial justice, "freely without sale, fully without any denial, and speedily without delay." A tax on justice is one of the worst sources of royal revenue, under whatever title it be imposed. At the present day the propriety of completely separating executive and judicial duties is the tritest truism. It is next to impossible that a sovereign should have the leisure, the attainment, or, in the most important cases, the impartiality, to administer justice in his own person. The guilt of tampering or of intimidation addressed to the judges, to whom the king has on the part of society committed his judicial trust, is a heinous offence in the meanest subject. When it proceeds from the king it is aggravated a thousand fold. But it is not enough that the hands of justice should be pure. Their purity should be beyond suspicion. For this purpose the independence of the bench ought to be maintained above all possibility of fear or favour. Perhaps there is no better evidence of what had long been only tradition concerning the personal attendance of the king in his courts of justice, and on the limits within which he was confined, than is contained in the case of jurisdiction of the House of Peers in the year 1666. It is there said, that "when the king attends in the House of Lords in his judicial capacity, he sits but as chief justice, doing nothing singly, but by plurality of opinions, as when the kings would in person sit in the king's bench, which they have in former time done, where all is said to be *coram rege*, though now he never come there; and in our memory King James hath sate in the star-chamber." It is natural that the king's presence should be last seen in the courts, which were not made unintelligible to common understandings by the forms of the common law, and which, by retaining the longest the name and the character of his council, seemed to keep the nearest to his person. Serjeant, when elected speaker in 1640, tells Charles I. "My disabilities are best known to myself; and to your majesty, I suppose, not altogether unknown; before whom, in the course of my practice and profession, it hath been your goodness towards the meanest of your subjects divers times to do me the honour and favour to appear and bear a part as an ordinary pleader." So little did the Plantagenet generation know what they ought to have prayed for on this subject, that in a list of very bold articles presented by parliament, to which Henry IV. consented in the eighth year of his reign, there is found the following request. It was prayed his majesty, that, "considering the wise government of other Christian princes, and conforming himself thereto, he would assign two days in the week for petitions, it being an honourable and necessary thing that his lieges who desired to petition him should be heard." James I. had a great longing to exhibit every phasis of his learning to his subjects. After having been told in Wraynham's case by

Government and Laws.

the judges, *cessat regnare qui cessat judicare*, it is not surprising that he should think the opinion of Lord Coke, that kings of England were incapacitated from the exercise of any judicial functions, little short of treason. Nothing, however, is more fully settled than that, as on one hand, the House of Lords, the Privy Council, and the ordinary tribunals of the common law, derive all their judicial authority in the first instance from the crown; so, on the other, whatever judicial authority the king originally possessed, it was possessed as in a reservoir, and has since all passed out of him into the appointed channels of his courts.

Direct interference on the part of the crown with the integrity of the judges was unfortunately not peculiar to the Stuarts; but it ended with them. It was carried by them also to such extravagant and unheard of lengths, as to throw all previous outrages of this description into the shade. The ignominy of the imputation has rested therefore principally on their name. Elizabeth had the sense to respect the honour of the interpreters of her laws; so that Coke felt what he called the taking of auricular confessions by James to be a novelty and a disgrace. The course, however, of the whole judicial history of England teaches a great lesson: the extreme difficulty of maintaining freedom with dependent judges. The struggle began at Nottingham, with the treasonable surrender of the infant constitution of their country by Tresilian and Belknap, in their discretionary expositions of law to Richard II. The impunity of intervening centuries tempted the colleagues of Finch and Crawley to believe that, supported by a sovereign at least as arbitrary, they might in their day set parliament at defiance. Although their virtue often failed, yet, in the main, the judges of the supreme courts of Westminster did their duty beyond what could have been expected. Fortunately for their characters, special commissions, composed chiefly of courtiers, were issued on most occasions of jealousy and alarm. In consequence, they seem to have kept their ground in the confidence of the public much better than the subordinate magistrates, who were subject, but in a less degree, to the same influence. These latter never gave much satisfaction. The ancient conservators of the peace, instead of continuing to be elected by the freeholders, were turned, in the first year of Edward III. into nominees of the crown. The necessity of suppressing the malefactors, who appear in those days to have been at times encouraged by member of the nobility, could not prevent the justices so appointed, on the extension of their jurisdiction, from becoming speedily unpopular. A petition from the House of Commons, in the 11th Richard II., declares that "every freeman in the land would be in bondage to these justices." Even in the retrograde years between Henry VI. and VIII., the difference between the independent tribunal of a jury, and that of perpetual officers connected with the executive, was well established. The right that criminal proceedings should follow the course of indictment and of the common law, is repeatedly and earnestly urged. Juries had so far begun to do their duty, that the fiscal purposes of Henry VII. could only be carried into effect by enabling these creatures of his power, removeable at his pleasure, to try all offences except treason and felony by themselves. The restoration of a jury to its pristine rights was one of the measures by which Henry VIII. won, on his accession, the popularity which he afterwards so cruelly abused. This affectation of a return to the old constitutional character of the English courts of justice, was soon overthrown by terrible innovations, like the creation of the president and council of the north, and of the Welsh marches. The worst part of these novelties consisted in their in reality placing the judicial and executive authority in the same hands. What could the subject expect from a tribunal of which Wentworth was the president? Mr Hallam says that these and other irregular tribunals, when abolished by 16th Charles I., had usurped so extensive a cognizance as to deprive one third of England of the privileges of the common law. It was nevertheless reserved for the high churchmen of Charles II. in the year 1664, to return to the charge. Legislating against what they unjustly called seditious conventicles, they ventured to arm a single justice (it is necessary to remember only what were the dependent justices of those days) with the power of inflicting seven years transportation on a third conviction of the offence of worshipping God contrary to act of parliament.

The objection applies still more strongly to the original authority of the sheriff. The shrievalty was generally sold by the Norman kings, and was an office of great emolument, and still greater influence. The coroner, with his limited inquest of criminal police, was left to popular election. But the sheriff, from the conquest downwards, except during the sixteen years which intervened from the 28th Edward I. to the 9th Edward II., was nothing but the annually nominated servant of the crown. Great judicial authority was intertwined with his civil superintendence over his county; the more so, because the law has never sufficiently distinguished between acts which are judicial, and acts which are ministerial only. Although in the hundred and the county, as well as in the baronial court (not being courts of record), the freeholders were the real judges, both of law and of fact, the sheriff's authority was the subject of great alarm. The principal sources of this jurisdiction were by degrees turned into other channels. Criminal pleas were taken from him entirely as far back as Magna Charta. The complaint upon which that clause was founded had only sought that he should be restrained from hearing them except when assisted by the coroner. The confidence felt in the popular presence of that officer for decompounding and breaking up this dangerous identity of powers, appears by several other writs in Rymer. The justices-in-eyre, not being the same always as the judges of Westminster, were probably often but partial improvements on the local administration of the sheriff. Their circuits, however, facilitated the transfer of most of the civil as well as the whole criminal business into a more strictly and purely judicial court. The civil cases which were formerly tried by the sheriff are now cognisable in the county courts, established under the 9th and 10th Vict., cap. 95, and of which there are sixty in number.

From this brief review, it appears that formerly the judicial power was often placed in the same hands with the legislative and the executive. This probably never took place without the people suffering severely from it. The small territorial jurisdictions, civil or criminal, must have been the worst of all. The existence of other checks at present, and the vigilant rapidity with which public opinion keeps hovering over and bearing down upon all official misconduct, may blind us as to the importance of the principle itself. A hazard, of which the only actual mischief is in the precedent, may seem not too much to incur for the convenience of this or that exception. At the same time, no nation is wise which in such a case presumes too far upon its security. A judge, when member of the legislature or of the cabinet, is in a position which ought to create, both with himself and with the people, a degree of watchfulness, not to say jealousy, far beyond the case of other men. It is to be remarked, that the greatest of all exceptions which occurs in this respect in English practice, that of the Lord Chancellor, occurs in the very instance where the existence of the judge depends on the casualties of the ministry of

Government and Laws.

which he is a leading member. An examination of the judicial removals during the Stuarts shows the extent to which the hopes and fears of the bench were constantly played with. It was a system, and not an accident. Nothing short of the 13th William III. could have put it down. That statute altered the patents of the common law judges, from patents during the king's pleasure, to patents during their own good behaviour. The little that was left to be done, was done at the accession of George III. This last amendment consisted in excepting their commissions from the fate of all other crown appointments, that of being vacated on its demise. It was a very prudent waiver of the little remnant of arbitrary power which, strange to say, had in the interval been misused. But the waiver could of necessity be made by any actual sovereign, solely at the expense of his successor. If a stop had been put to the analogous suspicions connected with the promotions of judges and the translations of bishops, it would have obviated an evil of more frequent recurrence. On considering the elements of the character and of the happiness of the nation, the English people are perhaps not more indebted to their participation in legislation by means of the House of Commons, than to their share in the administration of justice in the capacity of jurors. Not only has the executive been kept at bay by their interposition, for the legal verification of the fact at issue, but the legislature has received more than one useful warning from their collateral influence on the law itself. For both these purposes it was indispensable that intimidation should be removed from a juror as thoroughly as corruption; and that offences imputed to him in the discharge of his duty should be investigated and punished as cautiously, as reverently, and before as impartial, if not as solemn a tribunal, as similar offences imputed to a judge. The day when, in Bushell's case, the court relinquished the pretension of fining or imprisoning a jury for its verdict, ought to be as memorable as any in the annals of the victories of justice. It heralded in, and was in no degree less important than, the day which made it impossible that any successor of Pemberton (for even the chief-justice who tried Russell had paid too much respect to freedom) should be arbitrarily displaced. In this point of view the dissatisfaction expressed by Jefferson with the corresponding rule in the constitution of the United States, that the judges are irremoveable, except by a resolution of two thirds of congress, is very surprising. The exception would seem amply sufficient to secure the legislature the necessary discretionary control. Considering the position occupied by the ordinary courts of justice in the United States and in England, it is impossible that they can make any serious encroachment on the other departments of the state, without a degree of negligence or connivance on the part of the legislature utterly inconceivable. The cry against judge-made law, on the ground of its being an unwarranted encroachment, appears also, to the extent to which the common law courts have carried their incidental legislation, to be quite unfounded; and most of all in England, where the common-law judges are much more justly liable to the inconsistent accusation of standing too stoutly upon the letter and strictness of the law, and of having brought on the necessity of an equitable jurisdiction and of irregular tribunals, from their narrow adherence to precedents and forms. They are not answerable for the main defects of the English system, whether in the body of the law itself, in the centralization of the metropolitan courts, or in the inadequacy of the local jurisdictions.

Executive power.

A government, where in point of form the legislative and judicial authority appears to emanate from the crown, is certain to have placed its executive power solely in the king. Long after the two former authorities have succeeded in gradually emancipating themselves from every thing but the antiquarian recollection of their original subordination, the latter arrangement will in all probability retain its pristine vigour. This is the consequence of the substantial advantages which belong to a single and permanent executive. Such, at least, has been the course pursued in England. The founders of the republic of the United States, from their near observations upon the French Directory, and from their personal experience of the disunion of executive committees during the war of independence, admitted the propriety of placing the necessary powers of the general administration in the hands of a single individual. The name, whether king or president, is hardly worth discussing. The great questions are, the mode by which this supreme magistrate shall be appointed, and the powers with which he shall be invested. In comparing with this view the English and the American systems, the principal difference between them is in the mode by which the executive is appointed, and not in the amount or nature of its powers. In their jealousy of the concentrating effect of power, the Americans have subjected all the members of congress, the senate as well as the house of representatives, and the office of president equally with the senate, to the principle of rotation; only differing in the degree of rapidity with which the elective wheel in the several cases performs its circle. By this specific the evil tendencies of political power are supposed to be reduced within manageable limits. Impartial spectators, on comparing the risks of hereditary descent as experienced in England, with the risks already manifested in the quadriennial presidential elections of America, may perhaps be disposed to decide in favour of an hereditary parliamentary title, with reference to the actual passions and prospects of society. A four years' lease of the president's chair may be too exciting a prize to be safely left to popular competition. Besides, the very character and abilities most likely to be admired, are those on which the temptations of such an elevation must act with the greatest force. It is one of the advantages of the English system, that whilst the doctrine of descent greatly limits the probability of dangerous talents in a sovereign, the mechanism of the constitution is so well arranged and uuderstood as to do its work without them. The powers vested in the royal executive are not extreme; for they are nearly the same as those which it has been found necessary to maintain in the United States, notwithstanding all the advantages of a new country.

Under an ancient but progressive government, the executive authorities of the chief magistrate, like all the other authorities of the state, must be capable of being considered in three different points of view. These are, the historical, the actual, and the philosophical. Its constitutional history will vary, both in the facts which it exemplifies, and in the reasoning by which it is explained, at different periods. The correct legal description of it at any given moment, for instance the present, can represent at most only the law and practice of the age. The philosophical conclusion, how far it ought to extend in reason, may be, and probably will be, only obscurely signified in either of those inquiries. Mr Allen, in his inquiry into the rise and growth of the royal prerogative in England, and Mr Hallam, in different parts of his constitutional history, have left little to be added upon the first division. Mr Bentham, in his treatise upon legislation, has generalized upon the last. The legal exposition of the second is all that Blackstone properly undertook. Nothing certainly can be more absurd than the language which he has copied, in order to express the paradoxical fictions of the supposed attributes of sovereignty, perfection and perpe-

Government and Laws.

tuity. The parliament which consented to describe the forfeiture of the crown by James II., under the euphonism of an abdication, proceeded in the selection of the word on many precedents. Their ancestors, at every compromise with royalty, had demonstrated much indifference to words, provided that the end and consummation were substantially achieved. In English constitutional law, an unlimited and almost oriental deification of expression is found alongside of rights strictly limited and specifically defined. The Plantagenets, however, were much more cautious than the Tudors in bringing this inconsistency to the test of a collision. Unluckily for the Stuarts, they were mystified by the welcome homage of servile civilians and meddling churchmen. By forcing on the solution of the problem, they learned too late, that from the fact of the prerogative being incorporated with the law, whatever was not found there could not possibly be within it. Even Locke's definition of prerogative, which Blackstone has thought fit to praise, is too liberal, not only for the rights of reason, but for the rule of law. "The discretionary power of acting for the public good" does not extend to all cases "where the positive laws are silent;" but to such points only as the constitution has expressly reserved for this discretion. Otherwise we come to the intermediate inherent power on which James I., in his Flowers of Grace, claimed for royal proclamations the force of temporary laws. The proper course on such extraordinary occasions is for ministers to act on their responsibility, and trust to parliament for an indemnity. The Stuarts were doomed to make the additional discovery that, among prerogatives strictly legal, there were some, both prerogatives of authority and prerogatives of revenue, which, being false in principle and mischievous in effect, the public had become sufficiently intelligent and powerful to recall. Our early kings, in the insidious reservations (*salvo jure coronæ nostræ*) by which they narrowed many of their most popular concessions, had succeeded in a great measure in rendering that part of the constitution unimproveable and fixed. This was the course, before notions of an abstract *jus regium* by consent of nations, or the doctrine of a native immortality in the prerogative, which acts of parliament even could not reach, had been yet imported into courts of law. A struggle which could only be kept up by these new and desperate assertions, was evidently near its close. These novelties were in part the penalties of the Reformation, at least as applied to England. Henry VIII. obtained for the crown a new prerogative on that occasion. It was a more dangerous one than perhaps all before it, in consequence of the greatness of the subject which it concerned. The act of supremacy was the corner stone of the high commission court. Mr Hallam truly observes, that "the real aim of the clergy, in enormously enhancing the pretensions of the crown, was to gain its sanction for their own." They played into each other's hands. If, as Mr Hallam affirms, the nation might be considered, up to 1640, as having been, "in regard to spiritual dominion, a great loser by the Reformation," it would have lost every thing in regard to the crown, had civil liberty depended on the loyal sophistries of the church. The apparent strength of the executive on the breaking out of the civil wars, presented so formidable an aspect, as to deceive even Strafford not only into a desertion of the cause of the people, but into the adoption of the language and sentiments of Laud. From the example of former times, and from the external superiority which necessarily surrounds the throne, he egregiously miscalculated the means of the two parties who were then about to decide this battle by an appeal to arms. It is scarcely less surprising, after its result, to find political judges like Jefferies so intoxicated by the saturnalia of the Restoration, as to continue to hazard these and similar insane *dicta*, down to the very eve of the Revolution. On that event the nation carried the principle of the exclusion bill by acclamation. The exclusion bill was looked upon, from the time that it was first mooted, as the extreme case. It was among the principal argumentative advantages of the Revolution, that it put an end to all discussions founded upon the supposition of inviolable prerogatives, then and for ever.

It is perhaps not too much to say that the *direct* prerogatives, in respect of authority, which were objectionable, are all either abolished, or, in case the law of England allowed of desuetude, are obsolete. Some few *incidental* ones remain, which appear to be in the course of removal; since recent legislation has happily shown a desire to look towards a reformation of the law. It is unfortunate that the direct prerogative, which is on the face of it the most revolting, nevertheless, from its having so long principally supplied the king's service with seamen, demands, in the immediate modification of it, considerable caution. Marine impressment, it must be remembered, came in, however, upon no supposed necessity of this nature. It is the remnant only of a doctrine and a practice which at one time included soldiers, and many classes of civilians. Like most other prerogatives, it was abused under Charles I. for the purpose of extortion. Several of the common people who refused loans are said to have been pressed into the navy. There has fortunately been such little demand for prerogative learning since the great argument of ship-money, that the judgment of Sir M. Foster in Broadfoot's case, in the year 1743, in support of the legality of impressment, was wanted to recall the attention of English lawyers to the several conditions which the law requires as evidence of a subsisting prerogative. The debates on the alien act revived these discussions for a season. The lawyer and the statesman look at questions of this kind from different points of view. The first regards what is; the second, what ought to be. For whether the particular powers are wanted, and where they should be placed, are further questions. In case these questions are settled in the affirmative, it is unwise, by division, rotation, or a multiplicity of checks, to reduce their efficiency below a certain point. Society loses more than it gains by such expedients, as often as necessary powers are thus incapacitated for the due performance of their functions. This was frequently attempted in ancient times. On the other hand, governments cannot be too cautious against the abuses which constitute the provocations to such restraints. Unjust interpositions of the *nolle prosequi*, and of pardon by the crown, gave popularity to the appeal of murder. Lord Holt, looking back rather than around him, called the anomaly "a noble remedy." Several petitions were vehemently urged by the commons of former days against the generous prerogative of mercy. The degradation by James I. of the prerogative of honours, by bartering them, for the first time in English history, for money, and the subjecting the peerage by Queen Anne to the personal ambition of a minister, have the same tendency. They bring the prerogative itself, as well as the subjects of it, into disrepute. The prerogative of making peace and war was tarnished by the base negotiations of Charles II. It was damaged later still, when Chatham himself was not able to withstand the electoral prejudices of his sovereign in behalf of a campaign in Germany. The observation may be extended through every department of administration. It applies especially to the formation and the government of so jealous and delicate an engine as that of a standing army. The moderation which the executive had displayed in the exercise of more qualified powers, could alone have introduced into and kept in the mu-

Government and Laws.

tiny act the clause by which courts-martial are enabled to punish mutiny and desertion with death. It was inserted for the first time in 1718; and it was only carried at the time by small majorities. Of the impolicy of creating an atom of waste power there can be no dispute. But if the power is really wanted, they are sorry horsemen who are obliged to keep the strength and courage of their horse permanently below his work, as their only means of riding him. On the supposition that the powers are fitting powers for the executive magistrate to possess, the appropriate remedy is to apply ministerial responsibility to such cases, and to take care that the responsibility shall be a reality and not a name. The healthiness and *vis medicatrix* of the general system must do the rest.

The prerogatives of revenue depend on a different class of considerations. The financial purchase of tenure by chivalry from Charles II. and the subsequent arrangements entered into on granting successive civil lists, have not gone so far towards completely sweeping out the holes and corners of the exchequer as might have been wished. The last fibres of the barbarous fiscal pretensions which flourished there in former days have still to be rooted up. The national revenue, properly considered, consists of the portion of his property which each subject contributes to the state, in order to secure the remainder. That being the just principle, its demands should be limited in amount to what is necessary for the proposed object, instead of setting a fiscal net to catch an irregular and indefinite number of certain matters. Further, by an accurate calculation and repartition, the necessary taxation ought to be equally borne, in respect of their means, by all the king's subjects, instead of falling upon particular individuals on the happening of particular contingencies. In its original state most of the ordinary or prerogative revenue raised the least possible sum with the greatest possible inequality and inconvenience. The greater part of what remains is only remarkable for its picturesque absurdity. There is, however, one terrible exception, far too monstrous to be left for mitigation to the humanity of the treasury. Nothing can be worse than the wholesale forfeitures and confiscations which still sweep in the train of our criminal proceedings. In spite of the praises bestowed by Blackstone on Mr Yorke's essay in defence of the law of forfeiture, and although the people owe the 25th Edward III., which has been called the magna charta of treason, almost solely to a squabble between the king and his grantees the barons, for their several portions of the spoil, according as the late owner had been found guilty of treason or of felony, it is impossible that the reason and humanity of a great country can much longer permit cruel iniquity, abandoned by the most civilized part of Europe, to be justified upon antiquarian learning or by metaphysical refinements.

Blackstone's declaration at the commencement of his chapter on prerogative, that the powers which are vested in the crown by the laws, are necessary for the purpose of society, may be thought even now, if their whole detail is minutely examined into, to go something beyond the truth. The exceptions, however, can be in practice of no great consequence. The most obscure member of parliament would have nothing to do at the present day but to attack any indefensible exception, by a motion for its repeal. From the era that a general control over the government passed into the House of Commons, influence has so much superseded force, that questions of pure prerogative have lost much of their importance. According to present usage, any transaction arising out of its exercise, if it is at all interesting or doubtful, must be brought sooner or later before the House of Commons. The difference in the three modes of proceeding, between which alone a minister has to choose, comes to little more than the option at which of its stages the transaction shall be brought there. This will depend on circumstances. It may be a case in which there is no pretence of a prerogative, as on a suspension of the habeas corpus act. Or the principle of a prerogative may be pretended; but it may be suggested that the means for carrying it into effect are defective, as was suggested in the alien act. If there be time to apply to parliament to strengthen the executive, a prudent adviser would recommend, especially wherever a continuous measure is required, of necessity, on the first of these supposed occasions, but on both of them would he equally recommend, that the authority of parliament should be called in. In case a temporary emergency arises, more especially one which will not wait for parliament, as in the instance of the embargo laid by proclamation upon vessels laden with wheat in the scarcity of 1766, every administration is bound to take the responsibility of the measures demanded by the emergency; and parliament is bound to indemnify the authors of them for venturing upon a discretionary rigour beyond the letter of every day's law. The third supposition yet remains to be mentioned. When a minister is confident of the existence of the prerogative, and that the necessity for exercising it has arrived, there can be no occasion that the immediate representative of the executive should advertise for a parliamentary discussion. Let him use the instrument in the manner in which it was left by the constitution to be used. The opposition for the time being have it always in their power (and may be usually trusted for the inclination, as in the late Dutch embargo) to press the question to issue, and obtain the opinion of parliament upon both the point of right and the point of policy. For, on state-questions of this description, the members of a government are as answerable to the community which they serve, for mistakes in policy, as for mistakes in right. The distinctions were only of use before the House of Commons ventured upon the general superintendence which it exerts at present. Blackstone observes, that "the king, in the exertion of lawful prerogative, is and ought to be absolute," subject to the responsibility of ministers. Yet, from the nature of the case, as it is now understood, the king cannot be more or less absolute, nor his ministers more or less responsible, within than without these bounds. An unlawful prerogative may be assumed, a lawful one may be abused. As long as the constitution lasts, the king is in both cases alike personally secure. The unconstitutional adviser is in both cases equally answerable upon impeachment, and to the same degree. The decision against general warrants, when the official practice of three quarters of a century was at last brought into a court of justice, exemplifies the jealousy of the law in its own defence. The truth is, that the most satisfactory account of the mysterious maxim, that the king can do no wrong, since for every act done by him there must be responsibility somewhere, is an innovation which even the Revolution itself did not immediately introduce. The earliest strong assertion of it which Mr Hallam has perceived, is in a speech by the Duke of Argyll in the year 1739. Public opinion must have stopped short indeed, when a Whig, like Burnet, thought ministers were liable for advice given at the council, but not for the resolutions taken there; that is, they were to be liable for their own words, but not for the act, which might be the act of the sovereign himself. Whilst this distinction remained in force, it was possible that the whole question in these cases might turn on the limits of prerogative, and on the fact, whether the necessity of coming to parliament for fresh power could be evaded. This distinction, or something not distinguishable from it, was the shield behind which, strange as it now appears, both Whig and

Government and Laws.

Tory ministers, Somers as well as Harley, alike retreated, since the Revolution.

Prerogative, as above treated of, regards solely the remnant of those powers and privileges which had been vested in the crown from time immemorial by the common law. What is left is a small portion of a heterogeneous sovereignty, which had been originally wrested from a weak community by mere force, or which pertains to principles and circumstances long since decayed. From a sort of obscure traditional feeling, the word prerogative is more associated in men's minds with the personal will and pleasure of the sovereign, than with his political and strictly legal duties. The thing itself has, however, gradually fallen into the general mass of executive authority. Considered in this point of view, great additions have in later times been made to it. These additions consist of powers derived directly from parliament, and transferred to the supreme magistrate on the simple supposition that they are necessary for the public welfare. The preliminary question, Are they indeed necessary? occurs still more naturally on a demand that new powers should be granted, than on the suggestion that ancient powers might properly be retained. It is only when that point has been made out, that a prudent legislature will enter on the consideration of the precautions by which their abuse may be prevented, whilst their efficiency is maintained. To mention only one or two examples: The patronage of office has its risks in a free government. Yet it must be remembered that Polybius saw, in the influence which the contracts and public works gave to the Roman senate, the necessary link by which its connection with the Roman people was held together. At all events, the disadvantages of the actual extent of ministerial patronage belongs to the greatness of the British empire, and to the nature of its colonial possessions. The most rigid economy can alone reduce it within certain limits. An enormous national debt must still leave the public burdened with the additional evil of a proportionately enormous fiscal law; more equal in its assessment than, but perhaps almost as harassing as, the ruder aids and incidents of feudal jurisprudence. It is made both more costly and more pernicious, from the childish weakness of insisting that the bitter pill, if it must be taken, shall be concealed under the form of indirect taxation. The difference in the powers, as given by the common law and by the riot act, to public officers over unlawful assemblies, is scarcely so great as to be considered a dangerous augmentation to the force of any government. At the same time, whatever it may be, the same authority, or something very like it, may have become necessary for the preservation of the peace, when a vast manufacturing population is collected together on one spot; liable to be thrown out of employment at every moment by the oscillations of trade; accessible, besides, and accustomed almost daily to the most inflammatory appeals. This is the case also with regard to the extension of a regular police, and to the employment of the military in subordination to a civil magistrate. The change, however, which would most surprise Whitelocke and the patriotic parliament-men who argued the militia question under Charles I., would be the mutiny act and the army list of the present day. They would think that the king might well consent to the concession of coming to parliament for its sanction, as his portion of the compromise. The balance of power in Europe was the only cause at first assigned in justification of a standing army; and it is still the burden of the mutiny act preamble. Our immense provincial dependencies have also to answer for it in part. However, another and a domestic necessity must have been silently making prodigious way, when so cautious a statesman as the late Lord Liverpool defended in parliament the numerical increase of the army, not by a reference to the state of Europe or the colonies, but by a comparison between the amount of the population now and in former times. It would be impossible to govern with so slight a pressure as society is at present used to, without a strong executive. It is fortunate, therefore, that, from the systematic regularity which prosperous civilization has favoured, the actual powers of the executive government have become more consolidated, and their operation more uniform. The effect of the whole is, that in Mr Hallam's opinion at the time of writing his invaluable work on the constitutional history of England, the English executive, "though shorn of its lustre, has not lost so much of its real efficacy, by the consequences of theRevolution, as is often supposed; at least, that with a regular army to put down insurrection, and an influence sufficient to obtain fresh statutes of restriction, if such should ever be deemed necessary, it is not exposed, in the ordinary course of affairs, to any serious hazard."

On the supposition that this opinion was correct at the recent period when it was delivered, experience alone can determine how far the supposed influence alluded to in it has been affected by the subsequent change in the constituency of the House of Commons. The supposed euthanasia of the English constitution, namely, the establishment of that simple monarchy which Hume and other writers have predicted as its natural fate, has been thrown back to an indefinite distance by parliamentary reform. If any thing like the same good sense and good fortune which have hitherto prevailed in the history of the people and their government shall be continued, there seems little reason why they should be thought to be hurried, by a measure of that principle and extent, within the perils of the opposite extreme.

Neither the principle nor mechanism of the reform bill has so changed the nature of the account. The difference of opinion entertained by different persons on a general comparison of the forces at work in the English constitution, seems of itself positive proof that the variance, whether before or since, has been only in the inclination, but that the constitution is on its balance still. At the same time it must be admitted, that the interest which was strong enough to carry the reform bill, is tolerably secure. It is not difficult to prognosticate what would have been the issue of open resistance to the new political adjustment which has been settled upon its terms. It was impossible, also, from the causes which urged it forward, that the adjustment could have been much longer peaceably delayed. The impoverishment of the crown by the alienation of the royal demesnes; its abandonment of claims and maxims become odious or ridiculous; its political incapacity to act on the House of Commons by the disfranchisement of old or by the creation of new boroughs; the scandal of private nominations, the still greater scandal of corrupt corporators and bribed freemen; the doors of parliament thrown open to the people through the publication of the debates by means of a daily, almost an hourly press; the increase of dissenters, displacing the monopoly of the clergy; a liberty, nay license, of discussion, popularising crude analogies to a new and kindred democracy in the United States, and reaching over every question and up to every individual in the land; public opinion circulating from one end of the kingdom to the other, and brought concentrated with electrical rapidity at any moment to any point; the rights of conscience, of free opinion, and of political equality, so proudly recognised that they overcame at last even all the recollections arrayed against the Roman Catholic persecution of Protestant reformers; the universal responsibility of ministers

Government and Laws.

for every act of government now as universally acknowledged; the rise of immense towns, swarming with active artisans easily excited and easily combining; the constant accumulation of numbers, competence, and intelligence in the great and powerful body of the middling classes; the disappearance of the last relics of feudal castes and prejudices; the swamping of the ancient historical nobility by a modern aristocracy of wealth, favouritism, and corruption; the final breaking up even of the court and country party, whilst in their stead had risen up and found themselves face to face, those two parties which must always exist in open commonwealths—on one hand, the honest and also the servile partisans of power—on the other, the seditious and also the constitutional friends of the people;—these are but a part of the alterations which had changed not only the face but the core of England. A new soil, so to speak, had been turned up. A revolution in society had outstripped the Revolution of 1688. The rights of Englishmen, as Blackstone calls them (but what are in truth the rights of man, wherever man is civilized enough to understand and to preserve them) had grown into fuller consistency and bulk. The national system, now in its manhood, made, as it were, more blood, and required that the arteries should be enlarged which were to carry it to the heart.

A political student, after looking at the points to which all governments should strive, at the imaginary commonwealths of theory, and at the degree of approximation which, from amongst their thousand experiments, mankind appears to have ever realized, may think that there is good reason to be content both with the end and with the means which the English constitution recognises and secures. He will perceive that English liberty was long heavily mortgaged, but that the mortgage was never foreclosed. Its standard-bearers were sometimes down, but the pennon itself was always flying. Nations who regard England as a model, whether to be copied or to be surpassed, should remember that no nation can hope to buy a suitable constitution ready made. The end ought to be one all the world over, namely, the happiness of the people. But the condition of the people may be so different, as necessarily to demand the greatest difference in the means. The quantities with which moral and political problems have to deal, so far from being fixed, are in constant fluctuation; and the truths which they have to establish can never be tried by taking extreme cases. An assimilation and correspondence between that which acts and that which is acted upon, are conditions grounded on the nature of the human mind. In no case is strict attention to them more indispensable than in the relation between a people and its institutions. The best security for this is gradual adaptation. The Americans take English experience and English character into new circumstances, with the woods to back them. They may ride with a looser rein, and may try bolder tricks in legislation, than, in an old, densely-peopled, and overwrought community, any person, at least any reasonable person, acquainted with human nature and the difficulties of the case, could venture to recommend. They will not undervalue the necessity of such compromises with the nature of things and of events; since, in truth, no country ever made a greater sacrifice to the predominance of circumstances over principles than America has made, and is still making, over half her empire, in the most fatal of all exceptions. It is a worse one than the barbarism of the barbarous age of Magna Charta; an exception limited not even by the test of freedom, but that of the colour of the skin. It may be doubted whether the English experiment would not have failed, as the same experiment failed elsewhere, if its authors had rushed in the first instance to the point where their posterity at present stand. Light things may hurry forward, but the elephant must make sure of every step he takes.

A free government must be complicated in its parts. The checks introduced by circumstances, habits, and opinions, and which have been subjected to gradual amendments, remain a hundred times more effectual than any mere appeal to reason, which is all indeed that a totally new system has to make. The latter, however theoretically superior, must trust to its argumentative merits for its hold on the minds and affections of mankind. Montaigne expresses great contempt for long philosophical discussions concerning the comparative advantages of different forms of government. When he refers not only in opinion, but in reality, to usage as the sole criterion in every case, he is guilty of a gross exaggeration. This however ought not to prevent due respect being paid to the truth on which the very exaggeration is grounded. The whole history of England is the narrative of a long preparatory schooling to fit its people for their actual institutions. Institutions certainly are faulty which cannot stand the more summary test of Pope, when he disposes of these questions by a single line, " whate'er is best administered is best." For this in sensible prose must be understood to mean that the government is best which contains the best provisions for securing a good administration of all public affairs which depend on the relation of the governors and the governed. This security, it will appear by the description which has been given, it is the great object of the English constitution to establish by the proper formation and distribution of the legislative, judicial, and executive power.

II.—Laws.

The civil law approached to the character of a universal language. The breaking it into fragments on the fall of the Roman empire, and the substitution in its stead of the coarse and mixed materials of the barbarian and feudal codes, had the effect of the confusion of tongues. Each code was nothing more than a partial dialect. Whilst the rest of Europe fell back more or less under the legal dominion of its ancient master, England alone stood out. It was impossible, however, that it could altogether resist an influence so universal; and it is probable that a greater impression was incidentally received than contemporaries were aware of, or than antiquarians have since been at the trouble to retrace. Mr Hallam observes that a good work, pointing out the extent to which the Roman law affected Bracton and his successors, is a desideratum in our legal literature. Nobody has yet felt a sufficient interest in, or been sufficiently conversant with, both systems to supply it. The distance to which England was thrown from the common orbit of classical jurisprudence, appears to have been even something more than the difference which separated the northern and southern divisions of France, where the one was subject to a customary, and the other to the Roman law.

English civilians and foreign scholars always treated the vernacular common law with the greatest possible contempt. John of Salisbury, in the reign of Henry II. calls it *aucupatio verborum.* Whitgift derides the learning which is learning nowhere but in England. Erasmus must have seen it to great advantage in the person of Sir Thomas More; nevertheless he mentions its professors in terms scarcely more respectful than the scurrilities of the college-play of Ignoramus, got up in its ridicule for the entertainment of James I. Evelyn is content so that he escaped from it with no harder word than " that impolished study." The provocation given by Law-Latin and

Law-French has since been got rid of; that of tenures and their commentators still remains. Any insular jurisprudence, growing up during the middle ages, must have certainly suffered in its philosophy and its symmetry by excluding the written wisdom of the Pandects. By way of compensation, it is suggested that the alienation was of great advantage to English freedom. Whatever was gained in this direction is probably to be attributed more to the class to which the professors of the two systems respectively belonged, than to the supposed exemption of black-letter precedents from the arbitrary spirit of the imperial constitutions. The Inns of Court were long the principal seminaries in which the gentry of England completed their education; whilst, in the universities, the foundations for the study of civil law rivalled those for the study of divinity. The civilians and canonists, cousins-german by descent, thus became twin-brothers in feeling. In fact, civilians were formerly almost always churchmen. The difference of pedigree between them and the common lawyers was visible down to the time of Laud. The civil law, in any comprehensive sense of it, may be said to be extinct in England. To the degree, however, in which it exists, the English constitution is likely to find as warm supporters at present in Doctors Commons as in Westminster Hall.

The first point, on inquiring into the laws of a country, is to ascertain where the power of making them is lodged. It is very desirable that, as far as possible, the power should rest exclusively with the distinct and supreme authority of a recognised legislature. In this manner, laws adequately and publicly discussed will receive perhaps as general and as efficient a promulgation as the subject admits of. Certainly no better security can be devised against the possibility of constructive and *ex post facto* liabilities, than the practice of open debates, and the rule that legislative measures shall be strictly prospective. The connection between legislation and legislature is the doctrine of the English law. It can nowhere be expressed more strongly. But the history of what is called the common law shows the difficulty of acting upon it throughout. Popular customs will have already taken root before a steady government is formed, or, at least, before it is so far universally established, as to take under its cognizance the whole field of legislation. With regard, therefore, to this class of self-sown customs, the best thing probably that the legislature can do, when it becomes adult, is to acquiesce in them. Certain divisions of the law, and those not the least intricate and important, will from time to time be elaborately commented upon in text-books. Particular rules will also be adopted by the profession; and these soon become the grounds on which properties and expectations rest. For instance, "the practice of conveyancers" easily goes the length of making by necessity the law in that department. Much more is this the case with the opinions and the practice of the regular tribunals. For this purpose it is by no means necessary that the statute-book should contain an intimation corresponding to the threat of the *Code Napoleon.* "Le juge qui refusera de juger sous prétexte du silence, de l'obscurité, ou de l'insuffisance de la loi, pourra être poursuivi comme coupable de déni de justice." Direct legislation must be infinitely more active, and must complete its work in a far more workmanlike way, than the parliaments of the Plantagenets, and even than the parliaments of to-day, not to leave vast chasms for judicial construction to fill up. The English law at different periods has been indebted to all these collateral sources in different degrees for accessions to its wealth. Nobody can now determine how far Alfred and our other supposed lawgivers collected or composed the documents transmitted in their names. It is not the less unreasonable to assume on that account, with Chief-Justice Wilmot and others, that the "common law is nothing else but statutes worn out by time." Madox has observed that the laws of the Anglo-Saxon kings are as different from the writings of Glanville as the laws of two different nations. Some of the points are brought out in contrast in the second volume of Mr Hallam's *Middle Ages*, p. 466. Yet, if we are driven to any particular date for the origin of the present common law, it must be a moment not much anterior to the age of Glanville. He wrote as early as the year 1180; and the laws called by the name of Henry I., which are in their spirit thoroughly Anglo-Saxon, must, by their mention of Gratian's decree, be as late as the very end of the reign of Stephen. Mr Hallam makes a very judicious suggestion. He supposes that these laws, like the water ordeal for the common people, contain the ancient usages of inferior jurisdictions, whilst the treatise of Glanville, he conjectures, comprehends only the rules of the Norman lawyers, by which, through the influence of the circuits, and by other means, the former were gradually superseded. The unwritten usages were become completely fixed by the time of Bracton's compilation, towards the end of the reign of Henry III. There are no grounds whatever for conjecturing that these fluctuations were preceded or ratified by any direct legislative notice.

At a later period, namely, in the year 1322, it was explicitly enacted that all matters to be established for the estate and welfare of the realm should be treated in parliament. After so solemn and public a declaration, it might much more plausibly have been supposed that every subsequent alteration, whether in the civil or in the criminal law, would be accompanied by a parliamentary sanction in evidence of its title. What a change, however, took place both in one and the other; yet no "statutes worn out by time" can here be pretended. It is indeed remarkable that the statutory changes long bear but a small proportion to those which were obtained from other quarters. Although usage after this period can have crept in only now and then imperceptibly, undoubtedly the sages of the law kept insinuating their opinions, even extrajudicially, from time to time into the system. But by far the greater part of the innovations, real and apparent, were derived through the means of judicial decisions preserved in reported cases, and argued out by help of what has been quaintly called the "logical deduceableness" of the principles of the common law. The grounds of every judgment were set out on the record till the reign of Edward III.; afterwards they were taken down by certain grave and sad men in the year-books; and latterly, they have been left to reporters of a less accredited description. These precedents constitute an immense repertory of case law. If regard is paid to the smallness of the basis compared with the vastness of the superstructure, the ordinary course will appear to have been the synthetical formation of general rules out of the application and extension of individual instances. The portion, however, is far from being inconsiderable, in which the judicial classification of particular facts has proceeded according to the *allegata et probata*, under certain established principles. Looking at the history of the science, Burke was justified in saying, in the report of the committee upon the impeachment of Warren Hastings, that "to give judgment privately, is to put an end to reports; to put an end to reports, is to put an end to the law of England." Reports of the leading cases are especially valuable where society and the law are in a state of transition. Without them, the law in such periods soon becomes what Lord Bacon says the law of his time would have become without the reports of Lord Coke, a ship without bal-

last. The whole equitable law of the court of chancery, now tied up as strictly as the common law itself, has been spun, with but very slight exceptions, out of maxims of conscience and limits upon discretion, laid down judicially at as late a day as that of Lord Nottingham and the Restoration. That part of the English system where at present the lucubrations of twenty years are more wanted than in any other, was still in its infancy little more than a hundred years ago. Sir Mathew Hale said, in 1672, "a little law, a good tongue, and a good memory, would fit a man for the chancery." Evelyn, noticing the death of Chief-Justice Treby, in the year 1700, adds, "The chancery requires so little skill in deep law learning, if the practiser can talk eloquently in that court, that probably few care to study the law to any purpose." Lord Nottingham could not have desired a successor more admirably qualified than Lord Eldon, to remove from his court the last traces of this reproach. His ingenuity and erudition, however, only added still further to "the mass of learning which no industry can acquire, nor any intellect digest." Vesey junior, and his voluminous successors, have accelerated the predicted "crisis of a necessary reformation, when our laws, like those of Rome, must be cast into the crucible. It would be a disgrace to the nineteenth century, if England could not find her Tribonian." (Hallam.) Mr Bentham admits that this legislative crisis will find, in the store-books of our reports, materials of a higher and more authentic character than were ever in the possession of any other country. The amendments of the law in the session of parliament for 1852 were more extensive than those of any single reign since Edward I. They extend equally to common law and to equity, and remove many of the objections to the system of procedure, both in regard to expense and delay.

A wise legislature will establish municipal rights in all cases, when by so doing it increases the sum of human happiness. These rights must be derived from the several sources of human pleasure. They therefore necessarily regard property, person, station, character, or opinions. Rights are public or private. Out of the first arise questions between the governors and the governed; to the second belong the disputes of individuals. The classification of these two descriptions of rights, and the specification of the circumstances which are the occasions upon which they vest, constitute the constitutional and the civil code. But rights are delusive unless protected by adequate guarantees. It is the first object of the remedial law, therefore, to define the circumstances which amount to a legal violation of whatever rights the substantive law has conferred. If the injury is considered to affect the public, its recurrence is sought to be prevented by subjecting the wrong-doer to the penalties of the criminal code provided on behalf of society at large. If the injury is of a private nature, the party injured is entitled to recover damages in the civil court for his own personal satisfaction. The mode by which the appropriate legal remedies for an alleged injury are ascertained, is called the trial. Since every case may involve disputed points of law and fact, it is requisite to make complete arrangements for deciding both. The efficiency of a trial will depend upon the constitution of the several courts, and the rules for regulating their proceedings. The first part of this problem concerns the number and locality of the tribunals, the principle upon which each of them shall be formed (as whether of a single judge or more, and with or without a jury), and lastly, the scale of appellate jurisdictions. The chief considerations relating to the proceedings concern the rules of pleading and of evidence, or the method by which a party is required first to make his statement, and afterwards to prove it. When the trial has established the merits of the case, and fixed the nature of the remedy, nothing remains but that proper means should be provided for carrying the judgment of the court into effect. This can be only done by making the property, and, on just occasion, the person, of the defendant duly available to the requisition of the law.

1. *Constitutional Law.*—This has been treated of in the former section. The shape in which the Roman civil law has come down to us, as recast at Constantinople by the imperial jurists, contains not a syllable which can be referred to the supposed resemblance between the mixed forms of government of ancient Rome and modern England. Excepting a few slight privileges belonging to the peerage as members of a second legislative assembly, English equality recognises no distinction but that of aliens and natives. Our doctrine of the unalienability of birth-allegiance, and our restraints on naturalization, are pushed to an illiberal extreme. But it is a great blessing to have escaped the useless and onerous diversity of castes by which Roman policy was embarrassed and American freedom is disgraced. England is safe from the interminable questions of political rights and civil condition arising among the *ingenui, liberti, servi;* and under the discrepancies of the various kinds of citizenship and the *Jus Italicum* and *Jus Latinum.* Shades of colour have introduced the risk of even still more dangerous collisions into the United States.

2. *The Relations of Private Life.*—Under the English law these relations were for the most part either settled upon, or have been since gradually brought within, the true principle, namely, that of deriving from the connection the greatest advantage to both parties, which, on a comprehensive view of their interests, the particular relation seems qualified to produce. On legislating upon this subject, our law-makers have not overlooked the painful fact, that there is no occasion where it is more necessary to keep constantly present to the mind the line which separates morals from law. The poor-laws and the factory bill are doubtful exceptions, in which the feelings of society may be suspected of having got the better of its judgment. Otherwise, the law has generally forborne from becoming responsible for those private virtues which no law can possibly secure, and has shrunk from an interference far too powerful not to tend to defeat the end it is desirous of accomplishing. In the service of adults, the contract between master and servant is the only criterion both of their claims and of their liabilities. The maxim that slaves cannot breathe the air of England, has at length comprehended our distant colonies within its blessing. The extension of a haughty local privilege into a national truth is the proudest triumph of the humanity and justice of modern times. The relation of parent and child is placed upon proper grounds. Parental authority is reasonably limited to the degree of power necessary for the adequate performance of the duties which every parent is understood to undertake. The most faulty part of the legal distinction between legitimate and illegitimate children is not in the degree by which the parental obligation towards them is distinguished. The feelings of society must first alter, and the policy of our rules, and the most effectual method of attaining our object, must be carefully reviewed, or very little practical benefit will follow from a nominal amendment of the letter of the law.

The difference by nature and education between the sexes placed the female sex in the East, in Greece, and in Rome, in a permanent tutelary condition. Their disabilities were doubtless represented, as in the case of minors amongst ourselves, to be in reality privileges of protection. Modern civilization has transferred this state of imbecility from women generally, to women who consent to assume the character and *status* of wives. The marriage contract cannot be regarded as an ordinary partnership. Women are certainly the half of the species much the most interested

in the rule, that a contract, more or less resembling the marriage contract as it is actually established, should subsist. The only question which their advocates can raise must be upon its terms. It is admitted that the terms are partial. The question still remains, Can they be improved? Nothing is more imprudent than to volunteer speculative changes in an engagement of this domestic nature without infinite caution in examining into the capabilities of the case. It is impossible to equalize its effects and condition to the two parties. There is an extreme risk of injuring the female by the very precautions and facilities which it has been proposed to interpose in her favour. The interest which other parties (the children and society) have to keep families together, the first of those concentric circles by which a well-ordered community is formed, introduces a new and paramount consideration. The more the subject is reflected upon, the more will it appear that the English law of husband and wife requires only very incidental modifications. By the late amended marriage act (3d George IV.), the reluctant successors of Lord Hardwicke were compelled to retrace his steps, and to submit, on the marriage of minors, to the compromise of *factum valet, quod fieri non debet.* The debates on that occasion affirmed in the most striking manner the necessity of recognising the least of two evils in this delicate chapter of jurisprudence. No necessity, however, exists at all for making parliament the sole tribunal where a marriage can be dissolved. It is a singular anomaly, that this particular contract should become the subject of individual and *ex post facto* legislation in every case where parliamentary divorces for adultery are allowed to break in upon the ordinary law. Our practice does not leave a doubt that the contract should be legally voidable for adultery. But it is very questionable whether, on transferring this jurisdiction to a divorce court, as proposed by the recent commission of inquiry into the law of divorce, the interests of society in general, and of females in particular, would be promoted by the admission of any other grounds of divorce whatsoever. Nevertheless Cranmer, in the proposed reformation of the ecclesiastical law at the Reformation, was prepared to give to many of the causes on which a separation takes place at present, the effect of a complete dissolution of the marriage. The rule which, subject to a few exceptions, prevents a husband and wife from giving evidence either for or against each other, seems very unreasonable. The legal consequences of marriage do not depend, as Blackstone states, upon any canonical union of persons, which can be supposed to suspend or merge, during coverture, the legal existence of the wife. These consequences are much better accounted for by the rustic simplicity of ancient times, which regarded the wife as only a servant of a better fashion. It is evident that a family partnership, which, when it has once been formed, can be determined only by death or by criminal conduct of a serious nature, requires a conjugal superiority on one side or the other. In this view the law is censurable rather from the discourtesy of the occasional language of some of its authors, than the substance of its provisions. The superiority is certainly evident enough. There is the spiritual promise at the altar to obey, and the legal solemnity which makes it petty treason to kill her lord and husband. Marital restraint and correction carry the power of domestic discipline, in the case of a wife, a greater length than in that of any other servant except an apprentice. The principle of considering the wife incapable of committing certain crimes in the presence of her husband, owing to her supposed submission to his orders, is made additionally absurd by the inconsistency with which the supposition is applied. It is time that on one or two of these points the law should be put into harmony with the fact. There might also be a wholesome relaxation of the rule by which a married woman is prevented, under all circumstances except the civil death of her husband, from being sued as a single woman. The landed property of a wife could formerly be alienated only by a fine. It was imperfectly protected against the exercise of undue influence, on the part of a grasping husband, by her separate examination. Her real and also personal estate may be made safe enough at present. As far as property is concerned, the devices of a marriage settlement, and the interposition of trustees, seem to accomplish everything which can possibly be accomplished by law.

3. *Real Property.*—The lawyers of Greece and Rome had no idea of the necessity of two systems—one for land, and the other for goods. In England the systems are entirely distinct. The civil law of England during a very considerable period seems to have had little else but land to treat of. It characterized land by the expressive denomination of reality; and distinguished it still further by establishing its legal title and qualities on exclusively feudal principles. Hypothesis and research will be equally at a loss to make out any analogy between the Roman Institutes and Littleton's Tenures. The language of Craig would have been unintelligible to Papinian. Where the same word happens to be used, it only deepens the contradiction by the difference in its meaning. Dower, for example, by which the Romans described the property which a woman brought with her on her marriage, signifies, in our modern application of it, the life-interest which, on the death of her husband, the widow acquires to a third of his land. The changes in society gradually made it impossible to retain the strictness and also the peculiarities of feudal learning. The "old books" were already antiquated, and several of their cases seldom came into practice in the time of Sir Mathew Hale. The new reports, such as those of Coke, Plowden, and Dyer, the exact perusal of which he pressed upon his student, are now become "old books" themselves, and are approaching towards a similar fate, partly by statutory repeals, partly from desuetude or ignorance, under a still greater revolution in the law. The wave from the commonwealth which, during the reign of Charles the Second, carried off part of the rubbish of former times, did little in comparison with what was done in the first session of the reformed parliament. The abolition of fines and recoveries, the amendments in the law of inheritance and dower, and of wills, hold out substantial encouragement to expect that the labours of the different law-commissions will in course of time be brought to a satisfactory legislative conclusion. A code itself would be only a partial remedy, unless it superseded the necessity of looking back into the volumes which preceded it. Feudal doctrines are too completely woven into them ever to be worked out of their text. During centuries when the legislature either could not or would not act, judge-made law was by far the least of the two evils to which the country was reduced. The judges certainly did their best towards accommodating the law to the altered condition of society, by means of the only instrument in their power. But the course taken led naturally into a labyrinth of fictions and refinements, which it will now require pretty much the same astuteness to unmake as was originally employed in the making of them. The complaint is not that the law is difficult to be understood. That might be expected. What shocks a reasonable person at the present day, is the finding that so many of its rules, when they come to be understood, are irreconcilable with either common sense or with the usages of the community which they govern.

Thus, in descent, instead of regarding the just expectations of near relations, the law is occupied in tracing the blood of the first purchaser. In forfeiture, instead of balancing the claims of the family on one side, and the claims of injured society on the other, the law can see nobody but

the original feudal donor. In questions of the lawfulness of a distress, the difficulties do not turn on the point, whether the goods which have been seized represent under the circumstances the fair and natural security for the benefit which the owner of the goods has derived from the premises where they were found, but whether the landlord, on putting an occupier in possession of the premises, had taken care that the terms of the occupation were so expressed as to be sufficient technically to raise a tenure. Independently of judicial construction, successive legislative innovations have materially broken in upon the feudalism of the common law. This is the case particularly in regard to entails and remainders, and in the exercise of the testamentary power. The most important of all innovations is, however, the extent to which the doctrine of trusts and uses has brought the principal questions concerning land into a court, where forms and principles in many respects essentially differing from those of the old common law prevail. The intermediate legislation respecting uses, from 50th Edward III. cap. 6, to 27th Henry VIII. cap. 10, is a characteristic specimen of the English method of creeping on step by step, after the mischief has run, like the dry rot, into the frame of society, instead of taking a comprehensive view of the necessary consequences of the new system, and anticipating the confusion by such a conclusive statute as, after all its previous minute enactments, it was ultimately obliged to pass. It answers in civil to the cautious manner with which in criminal jurisprudence the law of *mayhem* advanced, taking successively the different parts of the human body under its protection, one after another, until at last came a general measure known by the name of Lord Ellenborough's act. Blackstone, writing in 1765, observes that the Chancellors, "by a long series of uniform determinations *for now near a century past, with some assistance from the legislature, have raised a new system of rational jurisprudence,* by which trusts are made to answer all the beneficial ends of uses, without their inconveniences or frauds." Considering the strictness of the doctrinal division between legislative and judicial authority, and the traditional attachment to juries, the national submission to this legal revolution, consummated by the great seal, is a remarkable proof of the impossibility of working the system of the common law in the present state of society. It may be questioned whether any country ever adopted, at so comparatively an advanced stage of civilization, so complete a change; with little notice beyond an occasional murmur in some quarters at what was going forward, and that general ratification on the part of the public in the consent that comes from silence. The nature of a jurisdiction like that of Chancery, must be to enlarge, and not contract, its circle. It is now some time since Mr Butler was of opinion that half the estates in the kingdom were held in trust. But there are further changes than those of form. The very substance of certain titles which make a great figure in the law-books is wearing out. Two species of incorporeal hereditaments, common and tithe, to which an extravagant and superstitious importance was formerly attached, seem shortly destined to disappear; and they will carry with them into oblivion a mass of favoured learning. Common of pasture and of estovers was supposed to be so necessary to the advancement of agriculture, and to the maintenance of tenantry and yeomen, that a case connected with it drew forth from Lord Coke the passionate exclamation, "God forbid that the law should not be so, for otherwise many commons in England would be avoided and lost." Long after the Reformation, a still deeper horror continued to be expressed by Spelman and the clergy, at the sacrilegious spectacle of tithe in lay hands, or of land discharged from the payment of tithe. When the necessity of statutes of limitation has been recognised in all other cases, and when even the crown has submitted to be barred by prescriptions of a reasonable extent, the ecclesiastical rule which sent back the proof of a *modus* to a time beyond legal memory (that is, previous to the reign of Richard I.) was no less impolitic than absurd. The tithe owner has to contend at present against passion and prejudice, as well as against reason. A violent re-action has taken place. The discouragement to agricultural improvements, from a surrender of a fixed portion of the gross produce, is a ground of objection in which the public at large are interested. The result is, a demand for a *general* commutation of tithe. Under the 6th and 7th Will. IV., cap. 71, and the various acts since passed for its amendment, a board of commissioners has been appointed to effect a commutation, either by a voluntary parochial agreement, or by the compulsory award of the commissioners, and the tithes are commuted into a rent-charge, the amount of which is adjusted annually, according to the average price of corn.

4. *Personality.*—It is agreed that Bracton borrowed the chief part of what he has said concerning personal property from the civilians. But the reader of the year-books finds himself at the reign of Henry VI. before goods and chattels have become of sufficient importance to make their way as the grounds of litigation into their records. The laws upon property of this description, and on personal contracts generally, are very much the same all the world over. This is probably to be accounted for, not by the supposition that similar laws must have had some common origin; but because these things are too perishable in their nature, and too much the subject of daily wants and traffic, to admit conveniently, under any circumstances, of any great deviation from a common line. The consequence is, that on this point, beyond some occasional quaint distinctions between what is realty and what is personalty, and a little absurdity concerning things which are merely the subject of base property and *nullius in bonis*, there is very little which can be noticed as peculiar in the English law. Where goods have been lost or stolen, the effect which, according to circumstances, prescription and sale ought to have in discussions between the original and the derivative owner, has been settled upon no discriminating principle. The rights belonging to an owner when he is out of possession have been slowly recognised in most countries. Blackstone hastily states, that unless a right of property were to be transferred by the sale even of stolen goods, in market overt, "all commerce between man and man must soon be at an end." He should have recollected that England offers the only exception in civilized Europe to the rule, "*nemo plus juris in alium transferre potest quam quod ipse habet.*" In the new questions which have arisen out of the extended intercourse and complicated interests of recent times, it is fortunate for the legal reputation of the country, that the demand for the development and application of the great principles of commercial and maritime law should have taken place at a time when Lord Mansfield and Lord Stowell presided in their respective courts.

5. *Private Wrongs.*—Every right must have its remedy, otherwise it is a right only in name. Verdicts with a farthing damages are sufficient evidence that the expressions *damnum absque injuriâ*, and *de minimis non curat lex*, are confined in practice within narrow bounds. The causes of actions are, in other words, a list of the cases which the law recognises as civil injuries, and which it accordingly promises to redress in that character. One of the great boasts of the English law is the means which it has taken to render illegal imprisonment almost impossible. This was at last obtained, but with infinite difficulty, under the final guarantee of the Habeas Corpus act. There is nothing otherwise remarkable in its estimate of the wrongs either to the persons or to the personal property of individuals, or in the general quality of the remedies provided by it. The injuries to real

property, and the peculiar remedies applicable in the several cases, partake strongly, at least in shape and in language, of the characteristic subtlety and jargon in which the law of real property itself is framed. There are instances, however, with respect to personal property as well as real, where the strictness of the rules at common law had the effect of a denial of right, and drove the parties into a court which undertook to adjust the remedy to the wants and feelings of society. Chancery would never have obtained a tenth part of its present jurisdiction, but that the common-law judges contented themselves with damages, instead of insisting that a contract should be specifically performed and goods specifically restored; but this is now altered by the 17th and 18th Vict., cap. 125; and unless they had obstinately refused, since the introduction of uses, to notice the existence of a trust. The bankrupt law is also about to undergo revision by the commission recently appointed, and it is to be hoped that this branch of our law will be put upon a footing likely to give, in its text and its administration, as much satisfaction as can be imparted to so untoward a subject. Nor does it follow that tradesmen who complain of the million that is discharged by a penny in the pound, are entitled to lay the blame upon either the policy or the execution of insolvent acts. The only effectual protection, that of more cautious credit, is in their own hands. The Roman system placed the debtor at the mercy of the creditor. The American system, according to Chancellor Kent, throws the creditor at the feet of the debtor. The experience of all countries seems to show, that in legislating upon insolvency it is impossible to reconcile the claims of humanity and of justice by the positive declarations of a universal rule.

6. *Criminal Law.*—Whenever the circumstances and motive under which a legal right is violated imply an injury to the public, it is reasonable that the remedy should cease to be solely of a private nature. The English law is defective in not endeavouring to combine reparation to the party directly injured, as a subordinate object. But it properly considers the mischief to the public, and the remedy for the public, as the paramount concern of criminal justice. The comparative alarm spread throughout society by different offences is the test of their several degrees of responsibility; nor is society entitled to take a criminal cognizance of them at all, save with the single aim of preventing their recurrence. The original point in this respect, from which the common law started, and the mode in which its circle widened, were too coarse and vague to admit of much discretion in the selection of the principle adopted, or of any very uniform correctness in its application. Civilization has tended gradually to exclude from the purview of human punishment the spiritual doctrine of expiation and the savage instinct of resentment. Proceedings *pro salute animæ* are left to the ecclesiastical courts; and the abolition, by 59th George III., cap. 46, of appeals at the suit of the party in all offences, has removed from criminal proceedings the last symptom of private vengeance. Up to a very recent period felony was heaped upon felony, as a matter of course, whenever a new or temporary provocation happened to arise. No wonder, where it was impossible that due attention could have been paid to the nature even of the specific evil and the proposed remedy, that the just proportion between the new offences and the great body of the criminal law should have also been neglected. In fact, they often seem to have taken their place by chance upon the penal scale. During the last few years the consolidation of great part of the criminal statute-law has been performed in a very workmanlike manner. The repeal of a multitude of obscure and almost conflicting enactments has been of great service to the public, and still more to practitioners. It has simplified the labours of future reformers. But a comprehensive view, a consistent direction, and a rational arrangement of the whole subject, is a task reserved for the commission now engaged upon it. The interests of society, as protected by the criminal law, are technically called the king's peace; and all offences against these interests are prosecuted in the king's name. But it is singular that, nevertheless, the burden and the management of criminal prosecutions, and, in popular language, the name even of prosecutor, should, contrary to the practice of many countries, be thrown upon the party injured. The principal legal consequence which has followed from taking the prosecution formally into the hands of the state is, that society obtains the evidence of the party injured, who would otherwise be excluded as being a party to the suit. The original object of using the king's name in this formal manner was probably to entitle the king, as a matter of course, to the penalties and compensations. A barbarous and fiscal rapacity was thus tempted to scatter wholesale forfeiture with indiscriminate profusion over the field of crime. The 25th Edward III., called the magna charta of treason, had no nobler origin than a contest between the king and the barons, which of the two should appropriate the confiscations upon conviction. They belonged to one or the other, according as the offence was treason or ordinary felony. It may easily be understood, therefore, what little principle exists in the rude classification of offences into felonies and misdemeanours, distinguished only by the nature of the punishment; the one being subjected to general forfeiture, and the other to special fine. Under these circumstances, a strict revision of the entire department of the criminal law, keeping steadily in view the one principle of the good of society, must bring to light anomalies and divergencies which it will be no less desirable than practicable to remove. This is likely to be the case much more in some questions than in others. For instance, the purely religious sentiment was formerly mixed up with the only consideration which can justify human laws in inquiring into offences against God; and it still partially remains so. Judicial perjury is punishable simply under the general description of being the violation of an oath. If the religious obligation is alone regarded, it may be contended with some plausibility that the breach and the offence must in all cases be the same. But if the danger to society be the point in question, it is clear that the danger must be materially affected by the nature of the case in which the perjury takes place. In some instances zeal without knowledge has been induced to pass the line by which morals ought to be always kept separate from law. The political economy of modern days has overturned many of the most sacred rules of policy and trade invented by the common-law wisdom of our ancestors. It is in vain that the corresponding statutes have been repealed, whilst narrow-minded judges feel a pride in proclaiming that unitarianism, forestalling, and engrossing, are still indictable misdemeanours. The same reasoning which annulled the statutory policy of the intermediate generations ought to avail for abrogating equivalent absurdities, supposed to have been embodied at an earlier period in the original structure of the common law. In many cases legal definitions, as formerly in larceny, or the specific enumerations contained in an act of parliament, or the purview of a preamble, or the recognised jurisdiction of our actual courts, may be found to fall short of their proper object. It is plain to the understanding of the present day, that the terms of the statutes of treason, which left even Strafford's case to forced constructions, were too monarchical. The decay of the ecclesiastical courts, of the court of honour, and the abolition of the star-chamber, threw loose many offences which have never been examined and arranged on system. It may be doubtful whether seduction and adultery are properly left to a civil remedy only. A doubt, however, can scarcely be entertained but that the indictable character of words spoken, as distinguished from

Government and Laws.

words written, ought not to be derived solely from their containing a consequent breach of the peace in their tendency to lead to a challenge. There is little foundation in reason for the general rule, which, in slander or libel, admits the truth to be pleaded as a justification always in an action, but never in a prosecution. A careful investigation of the true principles, which, in a compromise of difficulties, may be the best guides on many subjects, will lead to another very important consideration. A great deal of needless, and, what is worse, pernicious pains, appears to have been employed in turning into fixed rules of law what it would be much more satisfactory to the ends of justice to have left as questions of fact. This must happen in all subjects and occasions where the nature and tendency of the act depends on circumstances which it is almost impossible to define beforehand. Supposing what we see no reason to suppose that a common jury is incompetent to decide questions of fact of this description, it becomes the duty of society to create a competent tribunal. All offences of opinion are of this nature. But there are numerous others. Notwithstanding the complaint of Sir Thomas More against the judges of his day, that, in order to escape personal responsibility, they threw everything on the jury, it is evident that, honestly and dishonestly, English judges have brought many points, as legal conclusions of the science, under their own judicial authority, which, as questions of fact, would have fallen, and much more properly belonged, to the province of a jury. National character is involved in the history of the public institutions and policy of a country. England, both at home and abroad, labours under the imputation that the letter, and even the execution, of its criminal law, are severe beyond the example of other states scarcely its equals in general civilization. The difference would appear by comparing a scale of offences and punishments under the English law with a similar table drawn up according to the progressive mitigations which have been attempted by America and France. It need not be feared but that the experience of opposite systems, and a patient discussion of the peculiarities of England, of the nature and circumstances of its population, the distribution of its wealth, and the free character of its legislation, are sufficient securities against vague and theoretical innovation. The result would ascertain what degree of success has attended the humane endeavours of the enlightened statesmen of other countries towards the amendment of their penal codes, and whether any just cause can be assigned why England may not safely venture upon imitating their example. The comparison of the nature of comparative anatomy between the laws of different nations may be very useful. In this instance it would be most satisfactory, were it to terminate, as some confidently insist, in proving that England has already redeemed its right to the distinction which it lost in and after the reign of Henry VII.—*Nulli gentium mitiores placuisse pœnas.* The executions during the reign of Henry VIII. are reckoned by Hollinshed to have averaged two thousand a year. Towards the close of the reign of Elizabeth they averaged annually about four hundred. Notwithstanding the vast increase of our population, and the supposed increase of crime, the criminal return for 1830 gives, on 12,805 convictions, the sentences to death 1397, and actual executions only 46. In France the criminal return for the same year (1830) gives, on 4130 convictions, the sentences to death 92, and actual executions 38. By the parliamentary return for 1853, the convicted offenders in England and Wales were 20,756. Of these 55 were sentenced to death, but 8 only were executed.

7. *Courts of Justice.*—The occasions are few and strictly limited, in which the English law allows the party injured, or his immediate relations, to right themselves. A third person cannot justify interfering on behalf of the private interest of even his dearest friend. It is only as a member of society that he can step forward on the public grounds of preserving the public peace. The great singularity of the chapter on preventive justice in the English system, is not, as Blackstone states, that there should be one at all, but that it is so short. There is nothing, however, which a stranger is not privileged in doing, in order to prevent the commission of a felony. In other respects, every one is understood to have transferred the redress of whatever wrongs he may sustain, as well of a private as of a public nature, to the collective justice of the community. Under these circumstances, it is the duty of the community to establish tribunals for a prompt, cheap, and efficient adjudication of the differences which must necessarily occur. The necessity of reconsidering the constitution and distribution of courts, both of original and of appellate jurisdiction, has been at last forced upon the English legislature. Original tribunals may be separated or combined upon four principles: *First*, By the nature of the causes, whether civil, criminal, or ecclesiastical: *Secondly*, By the importance of the proceedings; that is, according to the value of the matter in dispute, or according to the amount of punishment to be inflicted: *Thirdly*, By territorial extent: *Lastly*, By the number and description of the judges, and by the different forms in which justice may be administered in each. The English system admits all these principles.

The supreme courts are classed on the first principle. They were originally founded upon a positive metaphysical division, which went so far as to parcel out particular classes of civil causes to particular courts. Thus all controversies between subject and subject were to be taken into the Common Pleas; all civil questions which might affect the revenue were to be decided in the Exchequer; whilst the King's Bench had the proper cognizance of all trespasses which savoured of a criminal nature, in right of its transcendent authority for the correction of crimes and misdemeanours. By means of rival measures of ludicrous trickery, hardly worthy to be called astuteness, these courts gradually obtained in most civil actions a concurrent jurisdiction. But this jurisdiction unfortunately remained stationary while society advanced. In course of time Chancery took under its charge the vast civil interests with which the common law refused to interfere. Common lawyers were for a time indignant; but they seem, after the first unsuccessful struggle, to have shrunk from entering into competition with the political ascendency of the Chancellors. Consequently, the greater part of this equitable jurisdiction is what no fiction or rule of court has since been ingenious or venturesome enough to reach. Soon after the Norman conquest, it was the policy, perhaps, of the government, but still more of the church, to separate judicially the civil from the ecclesiastical authority. The King's Bench has revenged itself on Doctors' Commons for the encroachments of Chancery, and has always taken jealous care, by its prohibitions, to keep the ecclesiastical courts within their peculiar province. The province is still, however, considerably larger than present opinion would have made it; for it would be difficult to make out how matrimonial and testamentary questions are properly matters of spiritual concern. The suspicion entertained by Mr Bentham, that the metaphysical classification of courts must have been the result of a scramble between competitors, is not confirmed by our legal history. The scramble began with and brought about the consolidation. Nevertheless, although at first a deliberate arrangement, it seems to have been an injudicious one; and as such, it has been in a great degree abandoned. Every classification of the kind multiplies the chances of clashing jurisdictions. It creates also an additional risk of a failure of justice; since there is a chance the more of a formal error, by mistaking the appro-

priate tribunal. Each court, having less to do as the business is more minutely subdivided, can supply the judicial demands of a wider area. Thus is superinduced the further disadvantage of extreme centralization. Circuits by the supreme judges at stated periods only partially mitigate a portion of these evils. They have been in use for many ages, and have the very desirable effect of bringing the metropolitan courts nearer to the great majority of the suitors of the kingdom; but it is difficult beforehand to make the calculation of the probable business at the several places of a circuit, with so much accuracy as not to become the occasion of one or other of opposite inconveniences. Causes are often hurried through with indecent haste, or are got rid of by an almost compulsory arbitration; or great vexation and expense are incurred in waiting for a trial, which, after all, is obliged to be put off until the next assizes. The Common-Law Procedure Acts of 1852 and 1854 conferred on the common-law courts a considerable extent of equitable jurisdiction in discovering evidence, examining the parties, issuing injunctions, pleading equitable defences, compelling the delivery of specific chattels, and the reference of disputed accounts.

The periodical visits of the supreme judges, and the presence and example of the powerful metropolitan bar, have doubtless a very wholesome influence in the provinces. They constitute moveable local courts for the time being. In the great majority of cases, trials at bar must have been always out of the question; and much more so, while the metropolis was a place talked of rather than known in remote counties, than at present. From the earliest times, therefore, the courts at Westminster could not dispense with justices in eyre travelling to the spot.

The inferior courts for the administration of justice were dispersed generally throughout the kingdom, but from one cause or other these petty tribunals have fallen into decay, although a new institution has recently been grafted on one species with an enlarged jurisdiction. These courts were— 1. *The Court Baron*, which yet obtains so far as relates to the surrender and admittance of copyholders to their estates, while its jurisdiction as a court of common law for the manor has fallen into almost entire disuse. 2. *The Hundred Court*, which was held for all the inhabitants of a particular hundred; but no resort to this court is at present ever made. 3. *The County Court.* Formerly this court had only jurisdiction to hold pleas of debt or damages under the value of 40s., but by the 9th and 10th Vict., cap. 95, the jurisdiction was extended to not more than L.20, whether in balance of account or otherwise, excluding actions of ejectment, or for libel, &c. This was raised by the 13th and 14th Vict., cap. 61, to L.50, or by agreement of both parties the court was empowered to try causes although the matters might be beyond its jurisdiction.

By an order in council, dated March 9, 1847, the whole of England and Wales was divided into sixty districts, and certain towns and places were specified where the court should be held at least once in every calendar month. The course of proceeding is regulated by statute, and the trial is by the judge alone, or with the assistance of a jury of five, whose verdict must be unanimous. There is a power of imprisonment for any period not exceeding forty days, and an appeal lies on any matter of law where the claim is above L.20, to the superior courts at Westminster.

The size of France more naturally led to great provincial institutions, like the old French parliaments, or the actual *Cours Royales*, with their divers subordinate jurisdictions. The different courts existing in England for different purposes vary considerably in the number of their judges, and in the forms by which justice is administered. Mr Bentham praises single-seated judicature. Aristotle, on the contrary, insists that one or more colleagues are wise precautions against the moral or intellectual obliquities of a single individual. The practice of England offers a choice of every kind. The varieties are varieties of accident apparently, not of principle. Courts of equity, and most of the courts which do not proceed according to the common law, have always afforded, and still afford, only a single judge. But the number in the supreme common-law courts fluctuated considerably in former times. That of the Common Pleas, for instance, has been nine, seven, six, four, and five; of which latter number the three principal courts of common law consist at present. On the circuit the number drops down to one, both in civil and criminal cases. The trial of a peer for felony takes place before the whole body of the nobility. The inferior courts vary equally. There are the mayor and aldermen of corporations, assisted, or not, by their recorder; magistrates with summary jurisdiction, one or two in certain cases, up to the indefinite scramble of the bench at quarter-sessions. When members of a corporate body, and justices of the peace, render their judicial services gratuitously, the financial objection of a numerous judicature is removed. But it is only the financial objection; and a remuneration, more than adequate to the services performed, is likely to be often got in local influence, or some more objectionable shape. When the aggregate numbers stop short of letting in the passions which seize upon all large assemblies, even the majority may be yet likely enough to want the requisite character and knowledge. It is absolutely necessary to keep down this risk within certain limits. But the importance of interesting the higher and middling classes in the administration of justice may counterbalance in this instance, as in that of a jury, a small percentage of errors.

If no very good cause can be assigned for the numerical varieties which appear upon the English bench on different occasions, it is perhaps still more difficult to give a rational account and justification of the distinctions by which the presence or absence of a jury is determined. The precise history of the institution, of its original object, and of the transitions through which it has passed to its present state, appears to be irrecoverably lost. But enough is left to show that it was a trial by neighbours, acting in the mixed capacity of witnesses, sometimes to facts, sometimes to character, as well as in that of judges ultimately determining the truth of the fact upon the result of the evidence. They were always the *patria*, but only in certain cases the *pares*, of the parties. As the law advanced to the dignity of a cultivated science, the line of demarcation between the facts which were to be proved, and the law which was to be applied to them, became strongly (occasionally too strongly) marked. If the temporary and casual inquest returned by the sheriff was recognised as the proper judicature for solving the question of fact, the permanent professional representative of the sovereign was alone competent to answer the question of law. The jury, growing up with, and itself a part of, the common law, was thus made the constant adjunct to its courts. It insured at all events publicity, without which every other excellence can give little security for real, and none for apparent, justice. Yet apparent justice is the source of the general confidence and satisfaction which forms one of the principal objects of government in all its branches. In their own limited departments, courts of equity, admiralty, and chivalry, arose under the civil law, and ecclesiastical courts under the canon law. Knowing nothing of a jury, they knew nothing of the above distinction; and the professional judge was of course entrusted with the decision both of fact and law. Before the passing of the 15th and 16th Vict., cap. 86, sect. 15, cases in Chancery, where an issue was directed, were the mere exceptions of practice. There is nothing in the great ma-

jority of the questions which come before any of these courts, as compared with the civil questions which are tried at the assizes, to warrant a difference of this description. The interposition of a jury is matter of command in the one case, and of prohibition in the other; yet the rule rests only upon prescriptive usage, and not on reason. The legislature has often dispensed with juries, for obvious reasons. It is easy to understand how a jury is too popular an institution to be trusted with the administration of unpopular laws; such as laws enforcing rates, excise, and customs, must unfortunately always be. A more agreeable reason will justify the absence of a jury in some, but in some only, of the questions left to justices of the peace. Many causes are too free from difficulties, and at the same time too frequently recurring, to render it necessary or prudent to fill a jury box by means of a legal conscription on their account. Twelve citizens need not be summoned from the farm-yard or the counter to superintend the prosecution of all minor offences, and on every affair of correctional police. Whilst accidental circumstances have had the greatest share in establishing the distinctions by which in the higher courts juries are admitted or excluded, it would be as well to see in what cases some better criterion can be found. This would be wiser than the opposite courses which have been recommended by the extreme advocates of reform; an indiscriminate reception, or an almost indiscriminate refusal. A jury is an excellent tribunal for solving and appreciating ninety-nine out of one hundred of the combination of facts with which criminal justice has to deal. It is thoroughly qualified to determine all cases of intention, and assess almost all questions of uncertain damage, as in actions of libel and of trespass. Whatever abuses may stain certain periods of our history, the institution has well earned the traditional reverence with which it is regarded. It is entitled, on collateral accounts, to the respect of the lawyer and to the gratitude of the people. The distinction by which a question belonged to the judge or to the jury, according as it was a question of law or of fact, impressed a peculiar character upon our legal proceedings. It was the occasion of the remarkable simplicity and precision with which these separate questions were early discriminated in the English law. The national character of Englishmen has become remarkable for its almost judicial sobriety, and for the degree in which a deep sense of justice and an invincible respect for property are singularly combined with popular public spirit. How much of these, one or all, may be owing to the immemorial co-operation of the people in the administration of the law, is more than any one can presume to say. The impression left by English history on Jefferson is recorded in his declaration, that he would rather live without parliaments than without juries.

It is for the interest of the parties as well as of the public that a suit should be brought to a final termination as soon as a reasonable certainty for a correct decision has been secured. A government is bound to make its courts of original jurisdiction as good as, with reference to the circumstances of the case, it has the means of making them. That is the first and indispensable security. Supposing, nevertheless, that there are grounds for suspecting a failure of justice in any instance, on account of misdecision either upon the fact or the law, the course to be pursued depends on the stage which the proceedings have reached. There can be no reason for withholding from the original court, if it has still charge of the proceedings, the power of doing justice. This is done in civil cases, in a court of common law, by means of a new trial. On the return of the record by the judges who were commissioned to take the trial at Nisi Prius, the court from which the record was sent can revise the law laid down at the trial by the presiding judge, and can also exercise a discretionary criticism on the verdict of the jury. In the event of the question being transmitted to a second jury, the judge commissioned to superintend, and the jurors summoned to rehear the facts, may be different individuals from those concerned in the former investigation; but the class which the inquest represents continues the same. It is not a superior court, but only another edition of the former. The judges on this occasion have frequently an opportunity of putting the parties to such terms as may appear to be advantageous to the ends of justice, especially with regard to the new evidence to be produced. It was, before the 15th and 16th Vict., cap. 76, a peculiarity belonging to the form of the action of ejectment, that a party might give himself the benefit of a new trial without the assistance of the court. In Lord Bath's case there had been five successive verdicts for Lord Bath before the House of Lords decreed a perpetual injunction. Justice Powell, in the year 1712 (1. Peere Williams, p. 212), observes that new trials from Nisi Prius are things of which he did not well know the foundation, but of which he had found the courts in possession. Judges of equity, possessing the whole case in their own hands, have allowed themselves a somewhat greater latitude of reconsidering and recalling their decrees, under the analogous forms of a rehearing and a bill of review. When an original court has once pronounced its final judgment, such a judgment is rightly made conclusive ever after, unless reversed by a higher court. There is sometimes the reality, and always the appearance of hardship in binding the losing party to the possibly hasty or prejudiced opinion of a single tribunal. He will often be desirous of appealing elsewhere for the chance of its reversal. One chance of this kind, if the superior tribunal to which it is carried up is at all properly constituted, will be enough. This part of any possible judicial arrangement contains a choice of evils. Unless a power of removal or of appeal be given, one act of ignorance or of injustice will be fatal to the unlucky suitor. The other side of the risk was exemplified in the skeletons presented by the inferior courts for counties, hundreds, and baronies. If the power is given, either both courts are really kept alive, in which case the temptation to run the gauntlet of both will often take a party through two proceedings, where he had much better have rested satisfied with one; or society and the law-books will be taxed with keeping up the cumbersome representation of a first court long after it has fallen into disuse. The differences between a writ of error from a court of common law and an appeal from the Court of Chancery are unimportant. They are the respective names by which the two systems mean the same thing. The supreme court of appeal from other courts of justice is the House of Lords. This high judicial office has been retained by them as the ancient *consilium regis*, which, during the early periods of English law administered justice with the assent of the king and the assistance of the judges; and it received statutory confirmation in the year 1340 from the 14th Edw. III., cap. 5. Their claim to an appellant jurisdiction over causes in equity on petition without reference from the crown, has been exercised since the reign of Charles I.; and their jurisdiction over causes brought on writs of error from the courts of law, although that power was originally derived from the crown, it was confirmed by the 27th Eliz. cap. 8. The opinion of the judges is taken on points of law on which the Lords wish to be informed.

Appeals in ecclesiastical, maritime, or prize causes, and colonial appeals, both at law and in equity, are determined by the judicial committee of the Privy Council.

Criminal proceedings are carried on with or without a jury. The latter are called summary convictions. They were unknown to the common law. At present they take

place in frauds on the revenue, and in many minor offences, before the particular persons appointed by the several statutes which have created these extraordinary jurisdictions. When the commissioner or magistrate has once pronounced his decision on the case as brought before him, he is *functus officio*. The privilege of appeal from his decision, in order to obtain a second inquiry into the merits, is not of common right; it only lies where it has been expressly given by act of parliament. The word is connected with the comparative novelty of the proceeding. For the word appeals had not passed beyond the spiritual courts until the time of James I. The earliest mention of appeals to the quarter-sessions is in the beginning of the reign of Charles II.; and towards the latter part of his reign they had come into general use. On the other hand, the writ of *certiorari*, by which the Queen's Bench removes before itself the proceedings of all inferior criminal jurisdictions, existed at common law. A certiorari has the object and effect of a writ of error, in an instance where, from want of learning, error was most likely to occur. For this purpose, whenever it is granted, the determination of the justices, like that of a jury in the case of jury trial, is final as to the matter of fact; and the superior court, in reviewing their judgment, notices nothing but what appears upon the face of the conviction. The power of granting certioraris has been taken away by express statutory prohibition upon many occasions since the Revolution. Nevertheless the power is considered by the Queen's Bench as so beneficial to the subject, that the extent of these prohibitions is as much as possible restrained by the utmost jealousy of construction. A knowledge of law travels down to the quarter sessions in the shape of opinions obtained from the metropolis, and in the persons of an attendant bar. If one or other must be dispensed with, it may perhaps therefore be fairly questioned whether the limited argument on a certiorari is not both more expensive, and at the same time less beneficial to the subject, than the more comprehensive re-investigation admitted upon an appeal. The conclusive nature of criminal proceedings before a jury depends on an absolute rule which the common law introduced, and which it has been able to preserve up to the present day in its own favourite tribunal. No man can be put in jeopardy twice for the same offence. As long as appeals for felony were in practice, this maxim might have been easily evaded. One precedent in direct contradiction to it is reported by Foster in the trials of the Jacobites. But when the jury has once been sworn on a charge within its jurisdiction, and upon a sufficient indictment, it is undisputed law that the prosecutor cannot elect to be non-suited, and that there can be no second trial. The points on which a criminal judgment may be falsified or reversed by the Queen's Bench, or by the House of Lords, either with or without a writ of error, are all independent of the merits. Wherever the proceedings below are annulled on the supposition that the party prosecuted has never been tried at all, of course he still continues liable to prosecution in the same manner as if the former nominal trial had never taken place. The doctrine of attaints in criminal cases was at no time held in terror over a jury. At moments of violence, arbitrary judges, dissatisfied with a criminal verdict, formerly imposed fine and imprisonment instead. This was equally unjust, and was illegal into the bargain. In the nature of things, however, there can be no reason why the presumption in favour of the correctness of a verdict should be placed higher in criminal cases than in civil. Yet the one is left carefully open to revision, while the other is as carefully closed. The distinction is partly the result of accident, partly of indifference. But it is probably in some degree to be attributed to the fact that it was an object to bring litigation sooner to a close, where, owing to the poverty of the parties, and to the rules concerning the costs of an indictment, the litigation would be prolonged at the expense of the public. The present popularity of the distinction is undoubtedly for the most part matter of tradition. The cause of it is to be found in the despotic practices of former times. The people gladly acquiesced in any rule which lessened the number of criminal prosecutions, and secured to a defendant the whole advantage which had been hardly earned for him by the rare contingency of a courageous jury. It is impossible that even the violent condition of unanimity can make the first impression of any court, especially of a court constituted like a jury, so completely satisfactory that the conclusiveness of a single verdict can be consistent in all criminal trials with the ends of justice. The rule in the present state of society operates entirely in favour of the prisoner. It must do so as soon as the crown has learned to exercise the prerogative of pardon on purely public considerations. Amongst these, and in the first rank, stands the necessity of protecting the conscience of mankind against the possible suspicion of punishing the innocent. If there has been any mistake in fact or in law, or if any fresh evidence has come to light, the prisoner is certain of receiving from the executive the full benefit of the discovery, in mitigation or pardon. On the other hand, unfounded acquittals are very injurious to the best interests of a community. They turn back on society offenders whom impunity has hardened. They embolden all who are tempted by vicious propensities to prey upon the public. They bear down the innocent man's appeal to a verdict in vindication of his character, by the cry of acquitted felons. They destroy the confidence of the people in the truth and efficiency of the law. The ancient scruples, by which the statutes of *jeofails* were not allowed to amend errors in indictments, had no connection with truth, justice, or sound humanity. As little can be said in behalf of any scruple which refuses society, for the punishment of a wrong-doer, the same assistance as it affords a private individual in satisfaction of his private injury. It will not be to the credit of the reason and the temper of the English public of the present day, if they are not able to remove this inconsistency between the two systems, by the interposition of checks and precautions, which, whilst they give a proper chance of justice to the public, shall secure a prisoner against any further hardship than that of having his case properly decided.

8. *Judicial Proceedings.*—On these points the English practice bears a remarkable resemblance to the Roman in some particulars, which have been comparatively abandoned in countries where otherwise the civil law is the principal authority. It is the more curious to find these coincidences between two systems, which are otherwise so different, that Selden observes they have not a term in common. The original writs of the common law, by being the tests whether a party has or has not a right, are rude approximations to a code. Their analogy to the set forms for actions adopted by the Romans is so striking, that Duck and Noy agreed that the writs in the *registrum brevium* must have been settled by great civil lawyers. Blackstone (vol. iii. p. 117) speaks as if some similar standard was in itself undoubtedly necessary to fix the true state of a question of right; and he even subjoins, that an equivalent method is recognised by all the modern legislatures of Europe. This is surely a proposition very difficult to be maintained in the presence of the contrary experience, both of Scotland, and of the English courts of equity and of Doctors' Commons. In the subsequent proceedings, most judicatures leave the parties to tell their story in their own fashion. But Mr Stephen, in his excellent work on pleading, shows, by reference to Quinctilian's account of the method of oratorical analysis, which he himself used in forensic controversies (B. vii. c. 1), how artificially the

logic of a Roman advocate was directed to the object of bringing out the point in issue. Looking at the different ways in which the testimony of witnesses may be extracted, Mr Bentham says that cross-examination is, both in the thing and in the name, peculiarly English; for every thing of the sort is excluded by the interchange of written interrogatories from the present usage and vocabulary of the civil law. However, in the seventh chapter of the fifth book of his Institutes, Quinctilian has again sketched as accurate a picture of examination and cross-examination as a Nisi Prius leader could desire. Every rule of positive law is necessarily founded on a balance of advantages and disadvantages. In many cases the line of prudent compromise between opposite mischiefs is extremely difficult to draw and to preserve. Wherever the line is taken, nothing is so easy or so unreasonable as to caricature it, by representing only the inconveniencies which every compromise assumes. This is particularly true with regard to judicial pleadings. They are merely the statement made by both sides of their case; nevertheless they are a subject which, on account of the opposite mischiefs of the Scottish and English systems, has lately been the occasion in both countries of elaborate debate and judicious propositions for their reform. The nature of the mischiefs in these two instances is just the reverse of what might have been expected. Scotch pleadings, which were carried on under the superintendence of the judge, erred by extreme looseness; whilst English pleadings, which, except in extreme cases, had been for ages left to the discretion of counsel, became celebrated for the characteristic error of an extreme strictness and technicality. The intermediate course taken by the Court of Chancery appeared upon the whole to be the most rational. As the new rules relating to pleadings (of Hilary Term, 1853) have come into practice, it may be confidently trusted that the common law will no longer labour under the evil of voluminousness, or of technicality. Originally, parties made their statements to the judge by word of mouth, with as little form as a complainant tells his story to a magistrate, or as counsel at present open the case orally at the bar. During this period a great deal would depend on the talents of the judge for abridging irrelevant details, and clearing up ambiguous expressions. Afterwards, towards the middle of the reign of Edward III. when writing became common, the substance of the altercation, to which the evidence and the argument were to be applied, was required (and very properly) to be put down in writing in the first instance. The moment of this transition was the golden age of English pleadings. Serjeants drew them, and judges settled them. The judges ceased by degrees to interpose at this early stage of the suit. But, according to the scholastic subtilties of that age, the science of special pleading was encouraged to become more minute and complicated. A proportionate degree of technical knowledge was rendered necessary for the judge, since he had ultimately to award the prize to the professional combatant who had manœuvred on behalf of his client with most success on this preliminary arena. Fitzherbert, Littleton, and Coke expatiate on the learning, the lucrativeness, the honour, and delights of pleading. The reports of Chief-Justice Saunders are the glory of this art; and his mind is a model of the sort of astuteness which it cultivates. The department calls for but a small, and that far from the highest, portion of real judicial ability. It becomes only prejudicial craftiness the moment that it passes the boundaries within which a strong and logical understanding would confine the speeches of advocates at the bar. The degree at which an intimate acquaintance with special pleading still ranks in the list of qualifications for the bench, is a proof how much that boundary has been overpassed.

Besides mastering the merits of his case, formal difficulties of great magnitude were, in this early stage of the inquiry, thrown upon an English lawyer (before the passing of the acts 15th and 16th Vict., cap. 76). In the first place, he had to select the appropriate form of action; and having done that, he must comply with the established principles on which the forensic argument was to be conducted, and which, *mutatis mutandis*, were equally applicable to all forms. Our historical sketch of the transitions of English pleadings shows what alone they ought to be when they are properly considered. If they are nothing but the statement made by the parties, of their respective cases, What is the only object of an intelligent and honest statement? It can be nothing else than to keep clear of extraneous topics, and to get to the point in dispute as soon as possible. As every legal question consists of the application of a supposed principle of law to some one or other supposed fact, the first thing to ascertain is, About what are the parties quarrelling? Do they differ in their view of the law or of the facts, or both? The alternative cases present no difficulty. When there is no dispute about the facts, there is a simple point of law for the opinion of the judges. It is at once raised upon what is called a demurrer. On the other hand, when the dispute turns entirely on the facts, what is wanted is, that they be brought out to the jury in so precise and definite a shape that it is impossible to mistake the point or points in issue. If the party is prepared to dispute the correctness of the law as applied to the supposed facts, and further also, the correctness of the facts as stated, questions of considerable difficulty and difference of opinion open on him. Must he enter upon both issues simultaneously? or may he take first one, and then the other? and, in the latter case, with which of the two issues, that of fact or that of law, ought he to begin? The English common law disposes of these considerations by summarily making an admission of the facts a condition of a demurrer. A legal proposition can seldom be put forward so manifestly erroneous that a defendant will not think it advisable to retain both chances in his hands. It is on the facts—namely, what he should prove, concede, deny—that he must be careful to watch over his own interests. Points of law will comparatively take care of themselves, and the benefit of these is also secured at all stages. Demurrers are freed in courts of equity from the above condition. The experience in equity by no means justifies the apprehension entertained by the common-law pleaders, that on the removal of the condition every cause at common law would be forthwith burdened with a tentative demurrer. The discretionary application of costs might easily be made a most effectual instrument for the suppression of such unwarrantable speculations as might at first arise upon a relaxation of the former rule. The abuses of special pleading have on many occasions induced the legislature to interpose; and now special demurrers are abolished by the 15th and 16th Vict., cap. 76, sec. 51. Particular defendants, as magistrates, for instance, have been favoured, by way of exception, with the privilege of pleading the general issue; that is, they are allowed to deny generally the wrongful act imputed to them, without being called upon to state whether they mean to deny the law or the fact, or to mention a single item of the hundred possible special grounds of their defence. The English system prides itself on its peculiar mechanism, every movement of which necessarily tends to a clear and single point. The plea of the general issue does much more than lose the advantage for which so much is sacrificed. It covers everything with a cloud. It gives the defendant the privilege of evading the duty of speaking out, by adopting a common form, which tells the opposite party absolutely nothing. The regulation which refuses a prisoner a copy of his indictment till he holds up his hand to take his trial, is scarcely in principle more unjust. Fraud lies in generalities. On the one hand,

a defendant or a prisoner has a right to know the particulars of the demand or of the accusation brought against him; something more than the mere assertion that he is liable to a demand or charge of some sort; what it is being left to appear on the day of trial. On the other hand, plaintiffs and prosecutors are equally entitled to know beforehand the particulars of the defence on which their claim is to be resisted; something beyond a direct negation. At all events, when the power of pleading the general issue is thrown over a party as a shield, the exception should rest on the nature of the case, and not on the authority of the person. A better distinction might be found than that of official station. Pleadings drawn up and communicated by the professional representative of the parties ought to contain a correct narrative of the transaction in writing. Thus prepared, they might be expected to be more complete, and at the same time more relevant and more concise, than any judge could have obtained from their own mouths if present. Yet what would be thought of parties in open court who were to ramble into the jargon and exaggeration of a declaration; or who should indulge themselves *viva voce* in the fiction of alleging the utmost preciseness of time and place, whilst every syllable of the allegations was perhaps notoriously and ridiculously untrue. It is difficult to account for the origin of such extravagant falsehoods. They are as indefensible in point of reason, coming from the pen of a pleader, as if they came from the principal himself, preferring his claim and conducting his cause in person.

9. *Evidence.*—What the pleadings have stated, it is the object of evidence to establish. One of the most difficult things to account for is the absurdity of the rules of judicial evidence, which have prevailed in all ages and over all countries. Sir William Jones observes, in his preface to Isæus, that "we may triumph in our elegant and philosophical theory of evidence, which Aristotle and Plato must have admired, and by the strict rules of which all trials in the world ought to be directed." No panegyric was ever less deserved. It is perhaps true that the English theory on this subject is less objectionable than the theory of almost any other country, inasmuch as its exclusions appear upon the whole to be fewer and more strictly limited. But it is faulty enough even in this respect; whilst whatever other defects may be found incorporated in its principles, they are likely to be felt more severely in practice, in consequence of the unbending rigidity with which every rule is enforced by English lawyers. Our judicial system is too careless in requiring or preserving preconstituted written evidence, even in the case of recurring events and deliberate transactions. The registries of baptisms, deaths, and marriages, are still left as a part rather of ecclesiastical discipline than of civil obligation. They are exposed to great irregularities and losses, whilst a general registry of deeds remains yet to be established. In criminal proceedings the attendance of witnesses on both sides is secured by summary methods. The duty of appearing for a prisoner as well as against him is equally a debt due to society by its members; although it is one which the law was disgracefully slow in recognising. In civil cases witnesses are obliged also to attend; nor can they insist upon more favourable terms than the tender of their expenses. The English law formerly admitted of four heads of personal incompetency in a witness: one intellectual, as want of sufficient reason; and three moral. Of these, the first was a want of religious belief, extending as far as to disbelieve the existence of a God and of a future state of rewards and punishments; but by the 1st and 2d Vict., cap. 105, such person may give evidence under the form of oath, which he may declare to be binding. The second was infamy of character, evidenced by a judgment of felony, or for some offence considered by the law as infamous. This has been done away with by the 6th and 7th Vict., cap. 85; and the last, or where the party has a direct legal interest in the cause at issue, or in the question asked, has been removed by the same statute, as amended by the 14th and 15th Vict., cap. 99. The only head of incompetency from family relationship, is the case of husband and wife. It applies to both, and to evidence offered either for or against each other. The only instance of incompetency from professional relationship, is the rule by which a lawyer is prohibited from giving evidence against his client concerning any facts with which he has become acquainted under the sanction of that relation.

The objections are equally fatal, whether the acts to which the testimony applies are sudden or deliberate. It would be as difficult to justify the want of distinguishing between these two classes, as to prove the propriety of the distinctions which, in some instances, prevail between the admissibility of the same evidence in criminal as in civil proceedings. The rejection of hearsay is also too extensive. It may be doubted whether the rejection should ever be carried further than to declarations made by a person whom it was possible to have produced as a witness, and who might have been compelled in the character of a witness to repeat his supposed statement under the sanction of an oath or other solemnity, and subject to cross-examination. It does not apply to declarations, themselves a part of the transaction. The tendency of the judges of latter days has strongly run in the direction of letting in evidence. A witness is not bound to answer any question tending to expose him to punishment as a criminal, or to any penalty or forfeiture. There can be no doubt but that the examination of a prisoner, humanely conducted, would be very favourable to truth. But there is much doubt whether even an open court could be trusted with the authority, and still more whether the public would be satisfied with the change. All the objections above enumerated go to the competency of a witness, and, where they apply, are fatal. All other objections are of minor consequence. They go only to the credit, and as such, they are questions, not of total exclusion, to be determined by the judge; but matter for observation, turning on degrees of credit, more or less, to be weighed by the jury. Two witnesses, or an equivalent, are universally required by the civil law. With us, one witness, if believed, was sufficient for all purposes, until parliament made two necessary in treason, and until a rough sort of comparative arithmetic established the demand for something more than a single witness upon a charge of perjury. Previous to January 1, 1838, it was necessary to have three witnesses to a will devising an acre of land, though a million in the three per cents. might be bequeathed by an unwitnessed testamentary paper; but now, by the 7th Will. IV., and 1st Vict., cap. 26, two witnesses are sufficient in either case. Courts of equity have imposed a limit on their encroaching jurisdiction, by allowing the positive oath of a defendant to be conclusive against the unsupported testimony of a single witness. The limit has probably a reference to the double origin of Chancery; first as a court of conscience, and next as more closely connected with the civil law. There are but few instances, and those introduced by act of parliament, where written evidence is of absolute necessity. The policy of the celebrated statute of frauds, 29th Car. II., cap. 3, was adopted from the French ordonnance of Moulins; and it admits of no exceptions where it applies. But writing is often used by the parties in transactions which are without the statute. The common law is equally strict in both cases, in preventing written instruments from being varied, added to, or explained by *parole.* The rule has been broken in upon to a certain extent, by a distinction between *ambiguitas patens et latens*, of which Lord Bacon has the credit. The best justification to be made for the exception which allows an ambiguity raised by

Government and Laws.

external evidence, to be also removed by external evidence, appears to stand on the following considerations. It restrains the fear of perjury within a much narrower circle. In the next place, the author of the writing had not equal means of protecting his intentions against an ambiguity of this description. The admissibility of copics is tried by the paramount rule, that the best evidence in existence must be produced. Mere declarations acquire no further validity by being committed to writing. They thus become only written hearsay. The mode of extracting oral testimony varies according to the courts in which it takes place. Very little can be added to the excellence of the system in the courts of common law. A witness there delivers his evidence *viva voce*, in the presence of the public, of the parties, and of the deciding judge. There is scarcely a limit to the range of examination and cross-examination, but the discretion of the court. The practice in courts of equity was before 1852 much more imperfect. The examination being conducted on written interrogatories, and by examiners out of court, lost all the advantages of *viva voce* suggestions on the spot, of cross-examination, and of publicity. The very demeanour of the witnesses was removed from the observation of the judge who had finally to determine on their credit. This defect has been removed by the 15th and 16th Vict., cap. 86. Either party may require the evidence to be oral. The proof of writings depends on the nature of the instrument, or on the mode of its execution. The English law does not affect to create a scale by which the value of particular evidence may be determined. With the same forbearance, it has refrained from establishing any judicial standard concerning the amount of evidence which is or is not adequate grounds for a judicial determination in any cause. These are questions of fact, on which (beyond a few hints, more valuable to a committing magistrate than to the deciding judge) the less that is said in law-books the better. The only security for correct decisions is the founding competent tribunals, and binding them to no other criterion than that of their own personal conviction. Mr Bentham's work on evidence, and his criticism on this branch of the English law, are perhaps the most original, and at the same time most useful, of all his writings.

10. *Judgment and Execution.*—The object of a civil action is either the recovery of a right certain, for instance, particular lands, specific goods,. a fixed sum as settled by the agreement of the parties; or the recovery of uncertain damages, more or less, according to the extent of the injury which the plaintiff shall be able to prove that he has sustained. The first class of cases, by the nature of the demand comprehended in it, relieves the tribunal from the vague and discretionary inquiries arising under the second. The amount of damage is a fact which a few impartial individuals taken from the body of society are in the great majority of cases peculiarly qualified to assess. This in civil actions is accordingly the province of the jury. They are likely to be far better acquainted than learned judges with the real elements on which the calculation ought to proceed. Damages evidently so excessive as to be explained only by the imputation of gross ignorance or corruption, are, however, one of the admitted grounds for sending back the case to a second inquest. The judgment against Titus Oates, for *scandalum magnatum*, at the suit of the Duke of York, where one of the juries of those days had assessed the damages at L.100,000, was reversed after the Revolution. The costs of a trial were never given at common law. In most cases, however, they have for a long time followed as the ordinary incident to judgment. Since the preliminary oaths and pledges of former days have fallen into oblivion, they constitute the only security of the defendant against frivolous and vexatious actions. Costs are too material an item in litigation to be properly bound in any court by one uniform rule. We are not disposed to recommend, for the sake of consistency, that courts of equity should be brought under the strictness. It would be a better approximation that the discretion of the courts of common law should be assimilated to the latitude which courts of equity have assumed. It is easy to enlarge the statutory power given in some instances to judges' certificates, or to grant an analogous authority to the jury. Certificates for costs might be made a sufficient restraint on fraudulent attempts against the credit of the law and the interests of society. There are occasions when personal vindictiveness combines unnecessarily an indictment and an action in misdemeanours, or when base practitioners multiply actions for the sake of costs against several parties who happen to be all legally liable. In ejectments, trespasses, libels, joint-stock companies, and all cases where many rights depend upon a single title, or the ends of justice may be satisfied by a single verdict, the law in its present state may be far too easily and too profitably abused.

In consequence of the feudal restraints on the alienation of land during a great period of English history, it continued to be only partially liable for its owner's debts of any description, and was not liable at all for ordinary debts by simple contract. The restraint went far beyond the policy of entails. To the extent that entails were permitted, a tenant for life might, as far as the principle was concerned, have bound the life estate, but nothing more; since that only is his own. This invidious protection of land, even when owned in fee against simple contract creditors, has been completely removed by the 3d and 4th Will. IV., cap. 104. Ever since the 29th Charles II., whenever land was at all liable, it was equally so although held in trust for the debtor, as when it was held in his own name. No feudal principle interfered to protect personalty from a creditor. Nevertheless, the absurd expression, that money could not be sold, and the maxim, so inconsistently evaded in many cases, that a debt or a right to sue another was not transferable, had an equally mischievous effect. No sensible reason could be assigned why the principle of foreign attachment should exist for the benefit of the citizens of London only, and not for the benefit of every creditor in England. There was even still less reason why funded property should be placed beyond the reach of the law, on the technical distinction arising from its subsisting in the form of an annuity payable by the nation to the holder of the stock. And, accordingly, the legislature has provided first by the 1st and 2d Vict., cap. 110, that a distringas may be obtained on stock by judge's order, and secondly, by the 17th and 18th Vict., cap. 125, that a judge may order the attachment of debts due from a third person to the debtor. And the judgment of a court of law, duly certified on a recovery against a stockholder, ought to have the same effect as the signature of the accountant-general of the Court of Chancery for authorizing a transfer of the stock. There is a dangerous tendency in facilities for credit to run to too unlimited an extent. The power of imprisoning the person encourages this tendency; and, what is worse, it is frequently resorted to in the hopes of laying the innocent relations of a spendthrift under contribution. The humanity of modern times has thrown open the doors of the debtors' gaol, by discharges under the insolvent act, and by abolishing arrest on mesne process under L.20. The security contingent on the person of a debtor was never good for much. In its actual state, it is of far too little value to be worth contending for.

For the prevention of crimes, the law seeks to obtain a counteracting influence in all directions; in its command over property, character, liberty, and life. The jury find merely the fact of guilt. The legislature has to most offences affixed a *maximum* of punishment, according to a

rude calculation of the nature of the offence and the interests of society. In a very few a *minimum* also is enacted. The power of arbitrating between these extreme limits, and of mitigating the penalties where no limit has been prescribed at the bottom of the scale, rests entirely with the judge. The gradation of punishments seems to call for further revision, with the object of proportion, mitigation, and precision. The calculation of public damage proceeds on the principle of prevention, and is set apart for the judge; that of private damage looks only to the satisfaction of the party, and belongs to the jury. The distinction arose probably on totally different grounds. It may be justified, however, by the observation, that the calculation in the instance of crimes does not depend on the individual case, but on a more comprehensive and general view of the bearings of the whole criminal law than a jury can well be qualified to take; and that a greater chance is thus afforded of an approach to that uniformity or average which it is so desirable to obtain. Pardon is a prerogative properly left with the executive. This is so in America, notwithstanding the foolish denial of the possibility by theoretical writers against republics, equally as in England. The exercise of the prerogative is of course greatly influenced by the recommendation of either the judge or jury. The abuse of it in favour of particular criminals was one of the scandals of many reigns. This had reached so extravagant a pitch, that Sir Thomas More praises Henry VIII. on the ground that never king granted so few. Nevertheless, such was the complication and severity of the law, that to execute it according to its letter would have been not only unpopular, but impossible. At the very period when particular pardons were a national grievance, general pardons were looked forward to as public blessings. It is observed by Sir Bartholomew Shower, that there were never five years without a parliament pardon, and that eleven were published by Elizabeth. "These," he says, "it was which made parliaments and crowns the darlings and the desire of the people." The dispute whether the crown can pardon on impeachments, was one of the remains of the jealousies of former days. It was raging, as a great political question, as late as the Revolution; and it is still open to argument as a point of law. The dissolving parliaments to save his favourites from impeachment, is charged even by Clarendon upon Charles I. as a denial of justice to the nation. There is a vast variety of writs of execution in civil suits of the most trifling moment. By way of contrast, Blackstone notices the slightness of the form by which a marginal note put by the judge upon the calendar, is the sole authority for the sheriff, even in a capital conviction. It is one only of many instances of the comparative value set by our ancestors on the formal administration of civil and criminal jurisprudence. The execution of the law in all cases, of whatever description, is intrusted to the official representatives of the executive. Special jurisdictions have their special officers; but, by the common law, the sheriff is in all judicial matters the proper minister of the crown.

Further information regarding the constitution will be found under Parliament.

ENGLAND, Church of. See England; Bishop; Benefice; Episcopacy; Reformation, &c.

ENGLISH CHANNEL, the *Oceanus Britannicus* of the Romans, and *La Manche* of the French, is that narrow sea or channel which separates the southern shores of England from the northern shores of France. It communicates on the west with the Atlantic Ocean, and on the east with the North Sea. It is narrowest at its eastern extremity where it forms the Strait of Dover, being only 18 miles across between Dover and Cape Gris-Nez. West of this strait it rapidlv increases in width; and between Brighton and Havre it is more than 90 miles across. Farther west, however, the peninsula of Cotentin projects from the French coast into the Channel; and between Cape Barfleur, its eastern extremity, and Catherine's Point on the Isle of Wight, the distance is scarcely 60 miles. Between Sidmouth and St Malo it attains its greatest width, being about 130 miles. At its western mouth, between Land's End in Cornwall and the island of Ushant on the French coast, the width is about 100 miles. The general average breadth is about 70 miles; east of Beachy Head it is 38, thence to Portland 67, and west of Portland 83 miles. It is estimated to have an area of 23,900 square miles; and includes the Channel Islands, the Isle of Wight, and the Scilly Islands. The ports on the French coast are shallow, none of them having naturally sufficient depth of water to admit men-of-war, while England, on the contrary, has some of its finest harbours on this part of its coast. To remedy this, the French have, at great expense, constructed at Cherbourg two harbours, a naval and a commercial, the former excavated out of the solid rock, and having a depth of 50 feet at high water. (See Cherbourg.) The English coast is 390, and the French 570 miles in length. A chalk ridge at the depth generally of from 12 to 30 fathoms crosses the channel at Dover, along which the submarine telegraph is laid. Hence the depth gradually increases, but it is at no part considerable. Westerly winds are prevalent, and render the navigation of the channel at times difficult. In stormy weather the surface is raised two feet or more above that of the North Sea, and the ports have several feet more of water in strong westerly winds than on ordinary occasions. The current, though not perceptible in any part, is generally, if not constantly, running from west to east, as is evident from the eastern tides being stronger than the western or ebb tides, and their running longer in stormy weather from the west. The channel abounds in fish, and the fisheries give employment to a considerable number of men on both coasts, the most important branch being the pilchard fishery along the coasts of Cornwall and Devonshire, and the oyster fisheries in the bay of Cancale.

ENGLISH LANGUAGE. When the Romans invaded the south of Britain, they found the country possessed by a people of Celtic origin, and speaking a dialect of the Celtic tongue. This invasion took place about fifty-five years before the birth of Christ, and the invaders retained their ascendancy till the commencement of the fifth century. During this interval, the Romans imparted to the rude natives some tincture of their own intellectual refinement, but must have left the British language as they found it: the foreign settlers were not sufficiently numerous to produce any change in the speech of the original inhabitants. When the huge fabric of the Roman empire began to decay, the Britons, who had the advantage of a remote and insular situation, found means to assert their independence. They however divided themselves into many petty states, and exercised many petty animosities, which impaired the national strength, and rendered them an easy prey to foreign invaders. The pirates of Saxony had long been accustomed to make occasional depredations on their coasts. The Picts and Scots, that is, the Goths and Celts of North Britain, infested them on the frontier; and at length the sense of common danger produced some degree of union in their councils and exertions. In this condition of their affairs, the Saxons obtained a permanent footing in the country. In the year 449, Vortigern, king of the Britons, had recourse to the aid of Hengest and Horsa, who first appeared as allies, but were soon converted into the most formidable enemies.[1]

The Saxons, like other Gothic tribes, derive their origin from a mighty horde which wandered from the east, and gradually overran the best portions of Europe. So early as the time of Ptolemy the geographer, this particular tribe had proceeded as far to the westward as the banks of the Elbe, and their primitive seat was between that river and the Eyder. Although at first they were not very formidable for their numbers, they gradually obtained a powerful ascendancy in Germany. Towards the middle of the third century, they entered into a league with the Franks for the purpose of opposing the Roman arms; and they afterwards enlarged their connexions and increased their influence till it predominated in a territory of great extent, reaching from the Eyder to the Rhine. This wide tract of country was not entirely peopled by Saxons: it included various nations, united by the ties of a kindred origin, and actuated by a sense of common interest or danger; but such was the ascendancy of the Saxons that they communicated their name to the entire confederacy, which, among other nations, comprehended the Jutes, who inhabited the south of Jutland, and the Angles, who inhabited the adjacent district of Anglen. Hengest and Horsa, the leaders whom we have already mentioned, were not Saxons, but Jutes. The subsequent emigrants were for the most part Angles, and their descendants were long distinguished by the name of Anglo-Saxons. The first part of the name denotes the predominant tribe, the second denotes the original relation of that tribe to the Saxon confederacy. The new country which they acquired was denominated Engla-land, or the land of the Angles. These German invaders established themselves in the most fertile districts, and gradually displaced the Celtic inhabitants, till at length they were chiefly confined to the fastnesses of Wales, where the prevalence of the ancient language still indicates the continuance of their race. Eight new states were formed by the Anglo-Saxons, who maintained their independence till the year 1016, when they were subjected to the yoke of a Danish conqueror. Canute, and his two sons, Harold and Hardicanute, reigned in England for the space of twenty-six years. A Danish court, and a Danish army, with other settlers, must have had some influence on the common speech, especially as the language of the conquerors was not very dissimilar to that of the conquered. But the laws and other public documents continued to be written in the Saxon tongue, and this new dynasty soon finished its course. The Saxon line of kings, which was restored in 1042, terminated in 1066, when Harold the Second was slain at the battle of Hastings, and William duke of Normandy ascended the throne of England. The Saxon dominion had thus continued for the best part of three centuries; and as the great body of the people was still of this race, it is obvious that their national language must have survived their political power. A writ in the Anglo-Saxon tongue was issued by Henry the Third, who began his reign in the year 1216.

In the language spoken by this ancient people, a great variety of literary reliques has been preserved. "The Anglo-Saxon literature," says Professor Rask, "possesses in many respects, even for its own sake, no small degree of interest. The numerous ancient laws throw considerable light upon the laws of the old Germans and Scandinavians, as well as upon their customs and civil institutions. The old chronicles and genealogies are important sources for the ancient history of the Low German and the Scandinavian nations. The various documents illustrate much in English history. Even the theological remains, shewing the constitution and doctrine of the ancient church, are not devoid of value for ecclesiastical history, especially to the modern English and Scottish churches. The translation of several parts of Scripture may likewise be advantageously employed in biblical researches. But of all, the poetical pieces are the most interesting, especially the great Anglo-Saxon poem in forty-three cantos, published at Copenhagen in 1815, by the Royal Archivarius G. J. Thorkelin,[2] which, from its commencement, he has aptly entitled *Scyldingis*. This is perhaps the only Anglo-Saxon piece possessing value on account both of its matter and style, particularly for the nations of the north; the principal hero being Swedish or Gothic, though the action lies in Denmark."[3] This ancient poem, more generally known by the name of *Beowulf*, has been translated into Danish verse by Dr Grundtvig, and ably illustrated by Mr Conybeare.[4]

The language of the conquerors became the language of the king's court and of all the courts of law. The pleadings of counsel and the decisions of judges were couched in a dialect which is commonly described as Norman French, but which in the mouths of English lawyers became utterly barbarous; and more curious specimens of composition are scarcely to be found than those which occur in the reports of cases written in a jargon half-French half-English. Lawyers have in all ages been conspicuous for their stiff adherence, with or without reason, to those forms and maxims in which they themselves have

English Language.

been duly trained. Long after French had ceased to be the language of legal proceedings, they adhered to the practice of reporting cases in the motley dialect used by their predecessors; for, as Blackstone remarks, "the practisers being used to the Norman language, and therefore imagining that they could express their thoughts more aptly and more concisely in that than in any other, still continued to take their notes in law French; and of course, when those notes came to be published, under the denomination of reports, they were printed in that barbarous dialect; which, joined to the additional terrors of a Gothic black letter, has occasioned many a student to throw away his Plowden and Littleton, without venturing to attack a page of them."[1] By the 36 Edw. III. c. 15. it was enacted that for the future all pleas should be pleaded, shewn, defended, answered, debated, and judged in the English tongue, but should be entered and enrolled in Latin. The statutes of the realm long continued to be promulgated in French; and it was only from the accession of Richard the Third that Englishmen were governed by laws written in their native tongue.

The Norman conquest proved fatal to the entire race of Anglo-Saxon nobility, many of whom lost their lives, and almost all of them their property. Not a few of the number sought refuge in different monasteries. Some of them became abbots, and others closed their career as monks. The lands of the Saxon earls were occupied by the Norman barons, who found it necessary to consult their personal safety by inhabiting fortified towns and castles. They must have had but little intercourse with their vassals, whom they probably did not respect, and whom they had much reason to fear. They retained their native tongue, and seldom acquired any other. For a long period of time, the peasantry continued unmixed with foreign settlers: they continued to cultivate the same soil; and when the written language of the kingdom had received many foreign accessions, the rustic dialect preserved its primitive elements with very few material changes. Much of the patois of different countries consists, not in adulterations of the modern, but in remnants of the ancient language. Many Anglo-Saxon words and idioms, unintelligible to persons of a refined education, are still current among the rural population of particular districts of England.

The English monarchs of the Norman race were liberal patrons of such literature as they themselves understood. French poetry seems to have been much relished at the court of England; and, according to a very competent judge, M. de la Rue, it was from England and Normandy that the French received the first works which deserve to be cited in their language. The works of many Anglo-Norman poets have been preserved, and they certainly form a curious subject of literary research. In this department, a learned lady, Marie de France, makes a prominent figure. Her poems have been recently edited by M. de Roquefort; and one of the historical poems of Wace still more recently by M. Pluquet. A history of the Anglo-Norman poets and poetry is speedily expected from M. de la Rue, who has already exhibited sufficient evidence of his being well qualified for such an undertaking.

Of the language spoken by the great body of the people about a century after the conquest, the reader may in some degree be enabled to judge from the following specimen of Lyamon's translation of Wace's *Brut d'Angleterre*. The translator describes himself as a priest of Ernlye upon Severn, and he is supposed to have completed his task about the year 1180.

English Language.

Tha the masse wes isungen,
Of chircken heo thrungen.
The king mid his folke
To his mete verde,
And mucle his duȝethe:
Drem wes on hirede.
Tha quene, an other halve,
Hire hereberwe isohte:
Heo hafde of wif-monne
Wunder ane moni en.[2]

"When the mass was sung, out of the church they thronged. The king amid his folk to his meat fared, and many of his nobility: joy was in the household. The queen, on the other side, sought her harbour (or lodging): she had wonderfully many women." Here, and in a much more ample specimen of the same work, we perceive no mixture of French words. The idiom is essentially Anglo-Saxon, but with some indications of its being already in a state of transition: the vestiges of the language, in its more modern form of English, may be distinctly traced. Of the language in a state more considerably advanced, we find a specimen in a facetious poem published by Dr Hickes.

Far in sea, by West Spain,
Is a land ihote Cokaygne,
There n'is land under heaven-rich
Of wel of goodness it y-like.
Though Paradise be merry and bright,
Cockaygne is of fairer sight.
What is there in Paradise
But grass, and flower, and green rise?
Though there be joy and great dute,
There n'is meat but fruit;
There n'is hall, bure, no bench,
But water mannis thirst to quench.[3]

In this poem, which apparently belongs to the thirteenth century, we perceive a further deviation from the Anglo-Saxon idiom. In the preceding extract, the obsolete spelling is not retained, and the language is thus rendered more intelligible. The subsequent quotation is from a metrical history of England, written by Robert, a monk of Gloucester, who appears to have lived about the year 1278. This rhyming chronicle, as Mr Warton has remarked, is totally destitute of art or imagination. The author thus describes the island of Ireland, nor does he fail to mention its exemption from venomous reptiles.

Yrlond ys aler yle best with oute Engelonde.
The sea goth al abouten hym eke as ich vnderstonde.
More he ys than Engolond, and in tho south half he ys
Bradder and more of ynow than in the north ende y wys.
Aȝeyn the lond of Spayne he stond in the north syde ryȝt.
Selde snowe ther inne lith, and nameliche thre nyȝt.
So euene hot that lond ys, that men durre selde
Here orf in howse awynter brynge out of the felde.
Lese lasteth ther al the wynter: bute hyt tho more wonder be,
Selde me schal in the lond eny foule wormes se:
For nedres ny other wormes ne mow ther be noȝt;
And ȝef he beth thider bi cas from other landes y broȝt,
Heo dyeth thorȝ smel of the lond, other thorȝ towchyng y wys:
Eche gras that ther inne wexeth a ȝeyn venym yt ys.
For men that ben venymed, thorȝ grases of Yrlond
Y dronke he beth y clansed sone, thoru Godes sonde.
Hony and mylk ther ys muche, mony folk and bolde.
This ys the stat of Yrlond, as iche habbe y tolde[4]

Another chronicler, who however belongs to a period

English Language.

somewhat more recent, was Robert Manning, more commonly called Robert of Brunne. H has himself stated that he had resided fifteen years at Brunne, or Bourne, in the priory of black canons, when, in the year 1303, he began his translation of Grosteste's *Manuel des Pechés*. This version still continues in manuscript; but one portion of his historical work, his translation from Langtoft, has been edited by the indefatigable Hearne, who rendered a similar service to Robert of Gloucester. The inedited portion consists of a translation from Wace's Brut. Peter Langtoft was an Augustine canon of Bridlington in Yorkshire, and is supposed to have died in the reign of Edward the Second. The subsequent passage relates to Sir William Wallace.

Whan Sir Jon of Warene the soth vnderstode,
That the Waleis gane brenne, an oste he gadred gode,
And went to Struelyne agayne Waleis William,
Bot the erle with mykelle pyne disconfite away nam;
And that was his folie, so long in his bed gan ligge,
Untille the Waleis partie had vmbilaid the brigge:
With gauelokes and dartes suilk ore was non sene,
Myght no man tham departe, ne ride ne go bituene.
Thore first tham tauht how thei did Fawe kirke:
Alle gate the brigge he rauht, of nouht our men were irke.
Whan the erle herd say, the brigge how William toke,
He douted to die that day, that bataile he forsoke.
The Inglis were alle slayn, the Scottis bare tham wele,
The Waleis had the wayn, als maistre of that eschele.
At that ilk stoure was slayn on our side
God men of honour, that wald to the bataile bide.[1]

A more curious specimen of composition is to be found in the Vision of Piers Plowman, which appears to have been written about the year 1362, and which is commonly ascribed to Robert Langland, a secular priest. The work, which comprehends a series of visions, is replete with satire on the different orders of men, especially on the clergy, both regular and secular; but it is likewise diversified by a succession of incidents, and furnishes abundant evidence of the author's talents for description. His mode of versification is not unworthy of particular notice. Alliteration supplies the place of rhyme: the corresponding sounds are at the commencement, not at the termination of words. Our extract from this remarkable work must necessarily be very brief.

And to the church gan ich go, God to honourie,
By for the crois on my knees knocked ich my brest,
Sykinge for my sennes, segginge my pater noster,
Wepyng and wailinge tyl ich was a slepe;
Thenne mete me moche more than ich by for tolde
Of the mater that ich mete fyrst on Malverne hulles.
Ich sawe the feld ful of folk fram ende to the other,
And Reson revested ryght as a pope,
And Conscience his cocer by fore the kynge stande.
Reson reverentliche by for al the reame,
Prechede and provede that thuse pestilences
Was for pure synne to punyshe the puple,
And the south west wynd on Saturday at eve
Was pertliche for prude, and for no poynt elles.
Piries and plomtrees were poffed to the erthe,
In ensample to syggen ous we sholde do the betere:
Beches and brode okes weren blowe to the grounde,
And turned upward here tayl, in tokenynge of drede
That dedlych synne er domys day shal for do us alle.[2]

After these specimens of verse, we shall exhibit a specimen of prose, selected from the seventh chapter of the Acts of the Apostles, as translated by John Wycliffe. The translator, who was born about the year 1324, and died in the year 1384, may be regarded as the father of English prose. He was the author of various works in Latin as well as English; but the most important of his literary labours was a complete version of the Scriptures. He was the great precursor of Luther, who appeared after an interval of one hundred and fifty years; and it may perhaps be safely affirmed, that to him the cause of reformation was more deeply indebted than to Luther himself.

"This Moises ledde hem out, and dide woundris and signes in the lond of Egipte and in the Reed See, and in desert fourti gheeris. This is Moises that seide to the sones of Israel, God schal reise to ghou a prophete of ghoure britheren; as me ghe schulen heere him. This it is that was in the chirche in wildirnesse with the aungel that spak to him in the mount Syna and with oure fadris, which took wordis of lyf to ghyue to us: to whom oure fadris wolden not obeie, but puttiden him awei, and weren turned awei in hertis into Egipte, seiynge to Aaron, Make thou to us goddis that schulen go bifore us; for to this Moises that ledde us out of the lond of Egipte, we wite not what is don to hym. And thei maden a calf in tho daies, and offriden a sacrifice to the mawmet, and thei weren glad in the werkis of her hondis; and God turnyde and bitook hem to serue to the knyghthood of heuene; as it is writen in the book of prophetis, Whether ghe hous of Israel offriden to me slayn sacrifices, either sacrifices of oostis fourti gheer in desert? And ghe han take the tabernacle of Moloch, and the sterre of ghoure god Renfam, figuris that ghe han maad to worschipe hem: and I schal translate ghou into Babiloyne. The tabernacle of witnessyng was with our fadris in desert, as God disposide to hem, and spak to Moises, that he schulde make it aftir the fourme that he saigh: which also oure fadris tooken with Ihesu, and broughten into the possessioun of hethene men, which God puttide awei fro the face of our fadris til into the daies of Dauid, that foond grace anentis God, and axide that he schulde fynde a tabernacle to God of Iacob. But Salamon bildide the hous to him.' But the high God dwellith not in thingis maad bi hond, as he seith bi the propnete, Heuene is a seete to me, and the erthe is the stool of my feet; what hous schulen ghe bilde to me? seith the Lord; either what place is of my restyng? whethir myn hond made not alle these thingis?"[3]

Contemporary with Wycliffe was Geoffrey Chaucer, who is commonly regarded as the father of English poetry, and who closed his life in the year 1400. Dr Johnson has remarked that "he may, perhaps, with justice, be styled the first of our versifiers who wrote poetically."[4] He was a man of original genius, improved by a familiar acquaintance with writers in several languages. For the native poets who preceded him, he appears to have entertained but little respect: he sought for better models among the Latin, Italian, and French writers, and in all these languages he found works which he either translated or imitated. He possessed a lively fancy, and was a shrewd observer of life and manners. He improved the language, and refined the taste of his contemporaries. He taught them to write, if not with new harmony, at least with new terseness. The work by which he is best known are his Canterbury Tales; and in these he not only exhibits many characteristic delineations of manners, but likewise evinces a rich vein of native humour. They commence with the following verses, which we have selected on account of the elaborate analysis to which they have been subjected by Mr Tyrwhit.[5]

[5] Canterbury Tales of Chaucer, vol. iv. p. 106. Lond. 1775, 5 vols. 8vo.

Whanne that April with his shoures sote
The droughte of March hath pierced to the rote,
And bathed every veine in swiche licour,
Of whiche vertue engendred is the flour;
Whan Zephirus eke with his sote brethe
Enspired hath in every holt and hethe
The tendre croppes, and the yonge sonne
Hath in the Ram his halfe cours yronne,
And smale foules maken melodie,
That slepen alle night with open eye,
So priketh hem nature in hir corages;
Than longen folk to gon on pilgrimages,
And palmeres for to seken strange strondes,
To serve halwes couthe in sondry londes;
And specially, from every shires ende
Of Englelond, to Canterbury they wende,
The holy blisful martyr for to seke,
That hem hath holpen whan that they were seke.

In the English language, as it thus appeared in the fourteenth century, the Anglo-Saxon vocabulary was still predominant, but the words had been greatly curtailed in their inflexions. This plan of simplifying the structure of speech is to be traced in other instances, where a rude or a strange race is mingled with a people who have cultivated a more complex language, bearing little or no resemblance to their own. The most essential part of the vocabulary may be acquired without difficulty; but it is not so easy to become acquainted with the inflexions of nouns and verbs, or with some other niceties which belong to language in its more complicated form. Many French words had now been incorporated with the English language; but the compositions of this period began to be marked by an affectation of words derived immediately from the Latin. If Chaucer did not set the example, he at least followed it; and when he aims at a more ornamented style, his use of such phraseology is sufficiently copious. In this respect, he was however exceeded by some of his successors, particularly Hoccleve, Lydgate, and Hawes, who inherited no portion of his strength and originality. Being deficient in taste as well as genius, they devised a verbose and languid style, interspersed with many sonorous and polysyllabic terms, with terms "aureate and mellifluate," which did not assimilate with their native tongue. The same false taste was at length communicated to the Scotish poets. Dr Nott has remarked that Barbour had given his countrymen a fine example of the simple energetic style, which resembled Chaucer's best manner, and wanted little to make it the genuine language of poetry; and that other poets of the same nation, particularly James the First and Henryson, adhered to this model of a simple diction, and affected no other ornament than what the proper use of their language supplied.[1] But ultimately the false taste, which had infected the English poets, was communicated to their brethren of the north.

Gower and Lydgate, whose names are very frequently mentioned with that of Chaucer, are well known to the readers of early English poetry. Thomas Hoccleve, whom his editor supposes to have been born about the year 1370, makes a more inconsiderable figure in the literary annals of that age, but seems nevertheless to claim a passing notice. He was deficient in the essential qualifications of a poet; and, in the opinion of Mr Warton, "his chief merit seems to be, that his writings contributed to propagate and establish those improvements in our language which were now beginning to take place."

The greater part of the fifteenth century was highly unfavourable to the progress of literature in England. The repeated contests for the crown, and the civil wars which they occasioned, were attended with a great waste of human blood, and with that incertainty of possession, and those reverses of fortune, which leave the mind but little relish for such pursuits as are chiefly calculated to gratify the taste. Some individuals, Sir John Fortescue, and a few other writers, have left favourable specimens of prose composition; and they were succeeded by others, who made further improvements in style. Among these we must include Sir Thomas More, Archbishop Cranmer, Sir Thomas Elyot, and Roger Ascham. But from the death of Chaucer, more than a century elapsed before another writer, deserving the name of a poet, appeared in England. This writer was Henry Howard, earl of Surrey, son and heir apparent to the duke of Norfolk, whom however he did not survive. He was beheaded in 1547, in the thirtieth year of his age. Although thus cut off before the full maturity of intellectual vigour, he lived long enough to effect some very material improvements in English poetry. The versification of preceding poets was more properly rhythmical than metrical. Although some improvements had been introduced by Chaucer, he left the number of syllables too indefinite, and did not reach the harmony and compression, of which this noble poet afterwards exhibited an example. One of the changes which he introduced was the use of the heroic blank verse. Langland and other poets had indeed dispensed with rhyme; but their alliterative lines were constructed in a very different manner. In the following sonnet, he bewails the death of another eminent poet, Sir Thomas Wyatt.

Divers thy death do diversely bemoan:
Some, that in presence of thy livelihed
Lurked, whose breasts envy with hate had swoln,
Yield Cæsar's tears upon Pompeius' head.
Some that watched with the murd'rer's knife,
With eager thirst to drink thy guiltless blood,
Whose practice brake by happy end of life,
Weep envious tears to hear thy fame so good.
But I, that knew what harboured in that head,
What virtues rare were tempered in that breast,
Honour the place that such a jewel bred,
And kiss the ground whereas thy corpse doth rest,
With vapoured eyes, from whence such streams avail
As Pyramus did on Thisbe's breast bewail.

Before the close of the sixteenth century, the English language had in a great measure attained that form and structure which it continues to exhibit. A great improvement of taste had been introduced by a more critical and more general study of the ancient classics. William Lilly, the famous grammarian, who had learned Greek at Rhodes, and who had afterwards acquired a polished Latinity at Rome, became the first teacher of Greek at any public school in England. This was at St Paul's school in London, of which he was appointed the first master about the year 1500.[2] The language soon began to be more regularly taught in the universities. At Cambridge the study of it was zealously and successfully recommended by Smith, Cheke, and Ascham, who were themselves distinguished by their proficiency. The elegancies of Latin style began to be better understood, and monkish barbarism was gradually banished. Ascham and Haddon acquired distinction by the style of their Latin prose; and some of the verses of Leland discover a classical vein previously unknown to his countrymen. Before the close of the century, many of the Greek and Latin writers appeared in an English dress, and classical story, with classical

[2] Warton's Hist. of English Poetry, vol. iii. p. 258.

mythology, was rendered familiar to the common reader. In addition to the French, the Italian and Spanish languages attracted a great degree of attention; and from all these languages, especially the two former, many works were likewise translated. New sources of knowledge, as well as of fancy, were thus opened, and the English tongue was enriched with a more copious and variegated phraseology. Surrey and Wyatt were succeeded by poets of great genius, by Shakspeare and Spenser, as well as by many others who, though of inferior powers, were yet possessed of a vigorous and brilliant imagination. The prose compositions of Bacon and Raleigh, partaking of the native energy of their authors, exhibited specimens of a condensed and forcible style, to which the preceding age had never attained. During the earlier part of the seventeenth century, ancient learning was assiduously cultivated; and men of great erudition, Selden, Gataker, and others, adorned the literary annals of their country. The prevailing taste of scholars had however a strong tendency to what was scholastic, if not pedantic; and even the poets, such as Donne and Cowley, substituted the subtilties of metaphysical conceits for flights of poetic fancy. Many words, derived immediately from the Latin, were introduced by the learned writers of the period to which we now refer. A considerable number of these has been subsequently rejected, while others are incorporated in the vocabulary. In the mean time, English poetry had nearly reached its highest limits. Milton's Paradise Lost, so eminently distinguished as a work of creative genius, affords the most remarkable illustration of the compass, power, and harmony of the language. Nor is Dryden unworthy of being mentioned with this mighty master of the English lyre. His powers of mind were no doubt different in kind and degree, but he was possessed of a genius truly poetical; and his prose, as well as his verse, exhibits a rich and copious vein of English phraseology.

The subsequent progress of the language our narrow limits will not permit us to trace. The history of the Scottish language is involved in more obscurity. The Celtic tongue is supposed to have been originally spoken in every district of this kingdom; nor has it been found an easy task to account for the introduction of a Gothic dialect, bearing a very close affinity to English. That the Scottish language is merely a dialect of the English, seems indeed to be the more prevalent opinion; and this foreign speech is supposed to have been gradually adopted by the Picts, who are at the same time described as a people of Celtic origin. The ancient history of every race of men which is possessed of no ancient records, and which has not attracted much attention from more enlightened nations, must ever be involved in doubt and incertainty. In the present instance, we have little to guide our enquiries, besides a few scattered and contradictory notices, added to the ordinary and well-ascertained progress of human speech. When other records fail, the history of a nation may sometimes be traced in the history of its language; and a very moderate degree of reflection will enable us to determine the probability of a Celtic people thus unlearning their native tongue, and from deliberate choice adopting another speech completely and radically different.

Dr Geddes, in a Dissertation on the Scoto-Saxon Dialect, has strenuously maintained this extraordinary opinion, which has likewise been adopted by a more recent writer, possessing no portion of his acuteness or learning. " The names," it is stated, " of all the rivers, mountains, towns, villages, and castles, of any note or antiquity, from Berwick-law to Buchanness, and from Buchanness to Arder-Sier, are all evidently Celtic. We must then either suppose that the language of the Picts was a dialect of the Celtic; or that they were not the original inhabitants of the country; or, in fine, that, after the extinction of the Pictish empire, or rather its union with the Irish-Scots, the language of these latter universally prevailed, and effaced the very remembrance of its Gothic predecessor. The second of these suppositions is contrary to history; the third is belied by experience; the first then is the only one that is founded in probability."[1] This observation with respect to the prevalence of Celtic names, though too strongly stated, is not without foundation. We may therefore admit that the south of Scotland was at some remote period inhabited by a Celtic people; but it is not a necessary inference that this people must be identified with the Picts. Whatever hypothesis may be adopted, it is not denied that many Celtic names of places have been retained where the inhabitants have long ceased to speak any dialect of the Celtic language. It may very easily be conjectured that this primitive race of Celts was finally supplanted by new settlers; and that those settlers, whether Scandinavians or some other Gothic tribe, adopted many of the names which the original inhabitants had applied to mountains, rivers, and other conspicuous objects. That a similar process has been followed in innumerable instances, must be obvious to every person acquainted with the history of European settlements in other quarters of the globe: the native appellations are almost always retained to a certain extent, and are mingled with other names, borrowed from the language of the colonists.

If we should suppose the Picts to have been a Celtic people, a very hard problem will remain to be solved:—by what extraordinary means could a distinct race of men, placed in such circumstances, be induced to reject one language, and to adopt another? This radical and unprecedented change Dr Geddes is disposed to ascribe to the operation of such causes as the following; to the temporary subjection of the southern provinces of Scotland by the Northumbrians; to the immense number of captives seized during the ancient wars with the English; to the planting of English garrisons in several of the Scottish towns; to the amicable intercourse of the Picts with the English; and, finally, to the influence of Malcolm Canmore's courtiers, whom he supposes to have learned the English language from Queen Margaret and her retinue. But it may without temerity be affirmed that, in the entire annals of the human race, such an effect was never produced by such causes. In a more refined state of society, the love of knowledge, the hope of gain, or the influence of fashion, may induce many individuals to betake themselves to the acquisition of foreign languages; but the great body of the people will ever be disposed to rest perfectly satisfied with the speech, whether rude or cultivated, which they have derived from their parents. It is only by some great revolution, by a total conquest, or by an overwhelming extent of colonization, that the current language of a country can be materially changed. After the Norman conquest, when French became the language of the court and of the law, and when Norman barons were planted in almost every corner of England, did the combined operation of such causes eradicate the old, and establish a new language in its place? Many new words were unquestionably introduced, but these were merely engrafted on the old stock of the Anglo-Saxon. " Had the Saxon," as Dr Jamieson well observes, " found

[1] Transactions of the Society of the Antiquaries of Scotland, vol. i. p. 408.

English Language.

its way into Scotland in the manner supposed, it would necessarily have been superinduced on the Gaelic. This has always been the case, where one language prevailed over another; unless the people who spoke the original language were either completely or nearly exterminated. Thus was the Norman gradually incorporated with the Saxon, as the Frankish had been with the Latinized Celtic of France. But the number of Gaelic words to be found in what is called Broad Scots bears a very small proportion to the body of the language."[1] And this solitary fact is indeed sufficient to evince that the inhabitants of the south of Scotland cannot be sprung from Celtic ancestors. Dr Geddes has ventured to specify the reign of Malcolm the Third, which commenced in the year 1057, as the period of a general denization of the Saxon tongue in Scotland. "That monarch," he remarks, "had been bred in England, and married an English princess. Her retinue were all English. English, in consequence, would become the language of the court. The courtiers would carry it to their respective homes; their domestics would be ambitious to speak the language of their masters; and thus it would be gradually introduced into every fashionable circle."[2] But to introduce a language into every fashionable circle, is somewhat different from rendering it the current speech of the people: French has long been the court language, and the language of fashionable circles in England, and yet the great body of the people still persist in speaking English.

The insuperable difficulty of accounting for such a transition as has thus been supposed, a transition from a Celtic to a Gothic dialect, renders the conclusion obvious and unavoidable, that the Gothic speech of Scotland was derived from a Gothic race of ancestors. Nor is this conclusion altogether free from difficulties, though they are of very inferior weight to those which are to be deposited in the opposite scale. It is the opinion of a late writer, who has investigated the subject with much ability, that the Picts emigrated from Scandinavia;[3] and, according to this opinion, the Picts and Saxons must have spoken two dialects of the same original tongue. The history of these kindred dialects may be illustrated from that of some others, derived from the same Gothic origin. The Islandic, Swedish, and Danish languages are all descended from the ancient Scandinavian. Island, which, as the learned Bishop Müller has remarked, is entitled to particular attention as the foster-mother of northern history,[4] was peopled by a colony of Norwegians in the year 874. This race of men, confined to a remote island, and maintaining but little intercourse, either of peace or war, with other nations, has preserved its ancient language with singular purity.[5] The Swedes and Danes, more extensively engaged in the pursuits of commerce, and more closely connected with the rest of mankind, have exhibited a different progress: but while both languages have receded very widely from the Islandic, they have not receded very widely from each other; a similar state of society, similar relations with other countries, and the study of the same foreign authors, have produced corresponding changes in both. In the history of these two languages, we do not find a complete parallel with that of the Scotish and English. the Swedish and Danish are both dialects of the ancient Scandinavian, while the Scotish is derived from the Scandinavian, and the English from the ancient German. But the Scandinavian and the German proceeded from the same common stock; and when we ascend to a period sufficiently remote, they are only to be regarded as dialects of the same language.

It is not to be concealed that Barbour, Winton, Henry the Minstrel, and other early poets of Scotland, have described their native language as English.[6] This application of the name has been explained, with at least some degree of plausibility, by referring to the circumstance of the Gaelic being then denominated the Scotish language.[7] A Celtic and a Gothic dialect could not well be described by the same term; and "when, by a necessary contingency, the Gothic language had in the same space, though in different nations, retained much the same hues, the name of that dialect, which was spoken by the greater and politer people, was imparted to the other, inhabiting a contiguous part of the very same island."[8] Mr Pinkerton is less fortunate in another suggestion; namely, that it is not more strange to perceive that the Italian, French, and Spanish languages were originally termed Romance. They were all described by this common name, because they were all derived from the language of the Romans; but we are not inclined to believe that the Scotish and the English tongues stand in precisely the same relation to each other. (D. I.)

ENGRAVING.

ENGRAVING is the art of cutting metals, wood, and precious stones, and representing thereon figures, letters, or whatever device or design the artist chooses.

Engraving, being properly a branch of sculpture, is divided into several other branches, according to the matter on which it is employed, and the manner in which it is performed. This art is practised most commonly either on copper or steel, or on wood.

ENGRAVING *on Copper* is the making, conformably to some delineated figure or design, such indented lines on a smooth surface of copper, either by cutting or corrosion, as render it capable, when charged properly with any coloured fluid, of imparting by compression, to paper or any similar substance, an exact representation of the figure or design.

Whether we consider the art of engraving with regard to the utility and pleasure it affords, or the difficulty which attends its execution, we cannot but confess that on every account it deserves a distinguished rank amongst the polite arts. By means of this art the cabinets of the curious have been adorned with the portraits of the greatest men of all ages and nations; and it is by this art also that the paintings of the greatest masters have been multiplied, and the lovers of the polite arts enabled to enjoy those beauties from which their distant situations seemed to have for ever debarred them; while persons of moderate fortune have been enabled to become possessed of all the spirit and all the poetry contained in those miracles of art which seemed to have been reserved for the temples of Italy or the cabinets of princes. When we reflect, moreover, that the engraver, besides the beauties of poetical composition, and the artful ordinance of design, has to express, merely by the means of light and shade, all the various tints of colour and clear-obscure—to give a relief to each figure, and a truth to each object; that he has now to represent a sky serene and bright, and then one loaded with dark clouds—now the pure tranquil stream, and then the foaming sea tempest-driven; that here he has to express the character of the man, strongly marked in his countenance, and there the minutest ornament of his dress; in a word, that he has to represent all, even the most difficult objects in nature;—we cannot sufficiently admire the vast improvements in this art, and that degree of perfection to which it has at this day arrived.

Engraving is an art which for the most part is of modern invention, having taken its rise no earlier than the middle of the fourteenth or fifteenth century. The ancients, it is true, practised engraving on precious stones and crystals with very good success; and there are still many of their works remaining equal to any production of later times. But the art of engraving on plates and blocks of wood, in order to afford prints or impressions, was not known till after the invention of painting in oil.

The different modes of engraving are the following:—

1. In strokes cut through a thin wax, called etching ground, laid upon the copper, with a point, and these strokes bitten or corroded into the copper with aquafortis. This is called *etching*.

2. In strokes with the graver alone, unassisted by aquafortis. In this instance the design is traced with a sharp tool, called a *dry point*, upon the plate; and the strokes are cut or ploughed upon the copper with an instrument of an angular form, distinguished by the name of a *graver*.

3. In strokes first etched and afterwards finished with the graver. By this expedient the two former methods are united.

4. In dots without strokes, which are executed with the point upon the wax or etching ground, bitten in with the aquafortis, and afterwards harmonized with the graver, by means of which instrument small dots are made, or with the graver alone, as in the flesh and finer parts, unassisted with the point.

5. In dots first etched and afterwards harmonized with the dry point, performed by a little hammer—called *opus mallei*, or *the work of the hammer*, as practised by Lutma and others.

6. In mezzotinto, which is performed by a dark barb or ground being raised uniformly upon the plate by means of a toothed tool. The design being traced upon the plate, the light parts are scraped off by instruments for that purpose, in proportion as the effect requires.

7. In aquatinta, a later invented method of engraving, in which the outline is first etched, and afterwards a sort of wash laid by the aquafortis upon the plate, resembling drawings in Indian ink, bistre, &c. See AQUATINTA.

8. On wood, consisting of a single block, on which the design is traced with a pen, and those parts which should be white carefully hollowed out. This block is afterwards printed by the letterpress printers in the same manner as a book is printed.

9. On wood, consisting of two, three, or more blocks, the first having the outlines cut upon it, the second being reserved for the darker shadows, and the third for the shadows which terminate upon the lights; and these are substituted in their turn, each print receiving an impression from every block. This mode of engraving is called *chiaro-scuro*, and was designed to represent the drawings of the old masters.

10. On wood and on copper. In these the outline is engraved in a bold dark style upon the copper; and two or more blocks of wood are substituted to produce the darker and lighter shadows as before.

Of all these modes of engraving, the most ancient is that on *wood;* or, to speak more properly, the first impressions on paper were taken from carved wooden blocks. For this invention it appears that we are indebted to the brief-malers, or makers of playing-cards, who practised the art in Germany about the beginning of the fifteenth century.[1] From the same source may perhaps be traced the first idea of moveable types, which appeared not many years afterwards; for these brief-malers did not entirely confine themselves to the printing and painting of cards, but produced also subjects of a more devout nature, many of which, taken from holy writ, are still preserved in different libraries in Germany, with the explanatory text facing the figures, and the whole engraved in wood. In this manner they even formed a species of books; such as *Historia sancti Johannis, ejusque Visionis Apocalypticæ*, and *Historia Veteris et Novi Testamenti*, known by the name of *Poor Man's Bible.* These short mementos were printed only on one side; and two of them being pasted together, had the appearance of a single leaf. The earliest date on any of these wooden cuts is 1423, and the subject is *St Christopher carrying the Infant Jesus over the Sea*, preserved in a convent at Buxheim near Menningen. It is of a folio size, illuminated in the same manner as the playing-cards; and at the bottom is the inscription, *Christoferi faciem die quacunque tueris. Illa nempe die morte mala non morieris. Millesimo CCCC° XX° tertio.*

[1] Such playing cards, however, were in use in Germany as early as the year 1275. See CARD.—*Ed.*

Upon the invention of moveable types, that branch of the brief-maler's business, as far as it regarded the making of books, was gradually discontinued; but the art itself of engraving on wood continued in an improving state; and towards the end of the fifteenth and the beginning of the sixteenth century, it became customary for almost every one of the German engravers on copper to engrave on wood also, as may be seen from the first printed books, in which the initial letters were for the most part highly ornamented with various appropriate devices. The works of Albert Durer in this style of engraving are justly held in the highest esteem. Italy, France, and Holland have produced many capital artists of this description; but, for boldness and spirit, the palm must be given to the prints of Christopher Jegher, who worked under the direction of Rubens, and was without doubt assisted by that great master.

The invention of that species of engraving which is distinguished by the appellation of *chiaro-scuro* is also claimed by the Germans, and seems to have been first practised by Mair, one of whose prints of this kind is dated 1499. Many excellent works in chiaro-scuro have also been produced in France; and in Italy it was honoured with the performances of Titian and Parmegiano; but the attempts of Jackson, Kirkall, and others in England, have not been equally successful. Since these times, which may be called the infancy of wood engraving, the art has been carried to very great perfection in Britain; and the present day may boast of higher attainments in this branch than were reached at any former period.

In Germany, about the year 1450, prints from engraved *copper* first made their appearance. The earliest date of a copperplate print indeed is only the year 1461; but however faulty this print may be with respect to the drawing, and however defective in point of taste, the mechanical part of the execution has by no means the appearance of being one of the first productions of the graver. We have also several other engravings, evidently the work of the same master, in which the impressions are so neatly taken from the plates, and the engravings so clearly printed in every part, that according to all appearance they could not be executed in a much better manner at the present day, with all the conveniences which the copperplate printers now possess, and the additional knowledge they must necessarily have acquired in the course of more than three centuries. Hence we may fairly conclude, that if these were not the first specimens of the engraver's workmanship, much less were they the first efforts of the copperplate printer's ability. It is likewise to be observed, that Martin Schoen, who is said, with great appearance of truth, to have worked from 1460 to 1486, was apparently the scholar of Stoltzhirs; for he followed the style of the latter in engraving, and copied from him a set of prints representing the passion of our Saviour. Now, allowing Stoltzhirs to have preceded his disciple only ten years, this carries the era of the art back to 1450, as was stated above. But there is no ground to suppose that it was known to the Italians till at least ten years afterwards. The earliest prints which are known to be theirs are a set of the seven planets, and an almanack by way of frontispiece, on which are directions for finding Easter from the year 1465 to 1517 inclusive; and we may be well assured that the engravings were not antedated, for the almanack of course became less and less valuable every year. In all probability, therefore, these prints must have been executed in the year 1464, which is only four years later than the Italians themselves lay any claim to. The three earliest Italian engravers are, Finiguerra, Boticelli, and Baldini. But if we were to refer these prints to any of the three, we should naturally conclude them to be the work of Finiguerra or Baldini; for they are not equal either in drawing or composition to those ascribed to Boticelli, which we know at least were designed by that artist; and as Baldini is expressly said to have worked from the designs of Boticelli, it appears most probable that they belong to Finiguerra.

With respect to the invention of *etching*, it is not well known to whom it ought to be ascribed. One of the earliest specimens is the print by Albert Durer, known by the name of the *Canon*, dated 1518, and thought by some, with little foundation, to have been worked on a plate of iron. Another etching by the same artist is Moses receiving the Tables of the Law, dated 1524. Etching was also practised in Italy soon after this by Parmegiano, in whose productions we discover the hand of the artist working out a system as it were from his own imagination, and striving to produce the forms which he wanted to express. We see the difficulty he laboured under; and, from the examination of the mechanical part of the execution of his works, we cannot doubt that he had no instruction, and that it was something entirely new to him. If the story be true that he kept an engraver by profession in his house, the novelty of the art is rendered so much the more probable. He died in 1540.

The art of engraving by corrosion, or what is called etching, with aquafortis, must have very early suggested itself to the discoverers of copperplate printing; for it seems to have been the method used by the manufacturers of warlike implements in their decorations of sword-blades and the like: and thus the same artists would soon perceive the facilities afforded by a mode at once easy and expeditious when applied to higher branches, such as the copies of pictures and works of art in general.

As to that species of engraving in which the modes of *etching* and *cutting* with the graver are united, it must have been found necessary immediately upon the invention of etching: it was, however, first carried to perfection by Audran, and is now almost universally practised, whether the work is in strokes or in dots.

Engraving in *dots* is a very old invention, and attributable to the Italians. Agostin de Musis, commonly called *Augustin of Venice*, a pupil of Marco Antonio, used it in several of his earliest works, but confined it to the flesh, as in the undated print of An Old Man seated upon a Bank, with a cottage in the background. He flourished from 1509 to 1536. We also find an example of this method in a print of "A single figure standing, holding a cup and looking upwards," by Giulio Campagnola, who engraved about the year 1516. The background is executed with round dots, made apparently with a dry point; the figure is outlined with a stroke deeply engraved, and finished with dots, in a manner greatly resembling those prints which Demarteau engraved at Paris in imitation of red chalk; and the hair and beard are expressed by strokes. Stephen de Laulne, a native of Germany, followed the steps of Campagnola; and many of his slight works are executed in dots only. Jean Boulanger, a French artist, who flourished in the middle of the last century, and his contemporary Nicholas van Plattenberg, improved greatly on this method, and practised it with much success. It is only, however, of late that it has been considered as an object worthy of general imitation. John Lutma executed this kind of work with a hammer and a small punch or chisel.

The method of engraving in *mezzotinto* was invented about the middle of the seventeenth century; and the invention has generally been attributed to Prince Rupert. See MEZZOTINTO.

Of the method of engraving in aquatinta an account has already been given under that word. (See AQUATINTA.)

But it appears to us not out of place to give the following general directions; and for more particular information the article already mentioned may be consulted.

Engraving in aquatinta was originally invented by Le Prince, a French artist. For a long time, however, his process was kept secret; and his prints, it is said, were at first sold for drawings. As a proof that the art rose at once to perfection, as has already been mentioned, the prints which were executed by him are still admitted to be the finest and best specimens of the art. It appears, however, that he was only acquainted with the powdered grain, and the common method of stopping out. The first who practised this art in England was Mr Paul Sandby. By him, we are informed, it was communicated to Mr Jukes, whose works afford excellent examples of the perfection to which the art has been carried; and although it is now generally practised all over Europe, yet in no country is this done with greater success than in Britain.

The principle of this process consists in corroding the copper in such a manner that an impression from it exhibits the appearance of a tint laid on paper, or a drawing in Indian ink. This is accomplished by covering the copper with some substance which assumes a granulated form, and prevents the acid from acting where the particles adhere; and thus the copper is only partially corroded. The more minute the particles are, it is obvious the impression from the plate will more nearly resemble a wash of Indian ink, or a drawing; but the larger the particles are, the granulation becomes more distinct. The powder or granulation is called the *aquatinta grain*, and is produced in two ways.

The process for using the powdered grain, which was first employed, is the following. The outline being etched on a copper-plate, some substance, which easily melts with heat, adheres to the plate when cold, and resists the action of the aquafortis, is to be finely powdered and sifted. Besides asphaltum, resin, and gum sandaric, the substances which have been mentioned in the article already referred to, Burgundy pitch, gum copal, gum mastic, as well as some other resins and gum resins, may be employed. Gum copal, it is observed, produces a grain which resists the aquafortis extremely well. Whatever the substance be which is to be employed, the great object of the artist in its application is, to have it equally distributed over the plate. This is an essential part of the operation, and requires considerable attention. The usual method is to tie up a quantity of the powder in a piece of muslin, and to strike it against a stick held at a considerable height above the plate. Thus managed, the powder settles equally over it. The plate being thus covered equally with the dust or powder, the latter is to be fixed upon it by the application of a gentle heat, to melt the particles. This is usually done by holding lighted pieces of paper rolled up, and moving them about till the whole of the powder is melted, which is known by its changing to a brown colour. It is now allowed to cool, and after being examined with a magnifying glass, if the particles appear to be uniformly distributed, the artist proceeds to the next part of the process.

Those parts of the design or drawing to be engraved, which are perfectly white, are to be observed and marked, and the corresponding parts of the plate must be covered or stopped out. This is best done by means of mastic varnish, diluted to such a consistence with turpentine as to work freely with the hair pencil. To give it colour, lampblack should be mixed with it, in order that the touches of the pencil may be distinctly seen. When those parts of the plate which are stopped out are sufficiently dry, a border of wax is raised round the plate, in the same manner as in etching, and the aquafortis, diluted with water, is poured on. This, being the most precarious part of the process, requires the greatest experience. When it is supposed that the aquafortis has remained on the plate for such a length of time that when the impression is taken it will produce the lightest shade in the drawing, it is poured off, and the plate is washed with water and dried. The lightest tints are then stopped out, and the aquafortis is again poured on; and this process is repeated as often as there are tints or shades to be produced in the plate.

Many plates are entirely etched in this way, by alternately stopping out and biting in. It is, however, found to be extremely difficult, and indeed impossible, to produce impressions of minute and complicated objects with the requisite degree of delicacy and freedom. To obviate this difficulty another process has been proposed, by which the touches are laid on the plate with equal ease and expedition as on drawings made with Indian ink. Fine washed whitening is mixed with treacle or sugar, and diluted with water in the pencil, that it may work freely. This is laid on the plate covered with the aquatint ground, in the same way as ink upon the drawing. When this is dry, the whole of the plate is varnished over with a thin turpentine or mastic varnish, and when this is dry the aquafortis is poured on. The varnish immediately breaks up in those parts of the plate where the treacle mixture was laid, and thus they are exposed to the action of the acid, whilst the other parts of the plate remain untouched. Thus the touches or places of the plate where the treacle has been applied are bit in deeper than the rest, and have the precision of touches done with Indian ink. The plate being thus completely bit in, the bordering wax is removed, by gently heating it with a piece of lighted paper. It is then cleared from the ground and varnish by means of oil of turpentine; and being wiped clean with a rag, it is ready for the printer.

But in this method of aquatinting it is found difficult to produce the necessary degree of coarseness or fineness in the grain; and plates which are engraved in this manner afford but a small number of impressions before they are worn out. On this account it is now more rarely followed.

The other method of producing the aquatint ground, which is most generally adopted, is the following. A resinous substance, as common resin, Burgundy pitch, or mastic, is dissolved in spirits of wine. This solution is poured all over the plate, which is inclined, till the whole of the superfluous fluid is drained off, and what adheres to the plate becomes quite dry in a few minutes. The plate being then examined with a magnifying glass, it will appear that the whole of the spirit having evaporated, the resinous matter is left in a granulated state, or is cracked in every direction, and adheres strongly to the copper. In this way a regular and beautiful grain is easily produced, which will be found preferable, at least for most purposes, to that which is produced by the former method. The grain being thus formed, the other parts of the process are conducted in the same manner as before described.

Such are the usual methods of conducting this process. We shall add a few hints which may be found useful respecting the different parts of it. With regard to the materials which are employed, it is to be observed that the spirits of wine should be rectified, and of the very best quality. Resinous matters, as common resin, Burgundy pitch, and gum mastic, yield grains of a different appearance and form; so that advantage may be taken of this circumstance by using them sometimes separately, and sometimes mixed in different proportions, according to the views and taste of the artist. Different proportions of resin may be employed to produce grains of different kinds. When a coarse grain is intended, a greater propor-

tion is to be employed; and when a fine grain is wanted, a smaller proportion of resin only is required. The proper proportions may be ascertained by providing a number of spare pieces of copper; on these the liquid may be poured, and the grain examined, before it is applied to the plate which is to be engraved. After the solution is made, it should remain undisturbed for a day or two, till the impurities of the resin have subsided, and the liquid becomes quite limpid. This is the best method of freeing it from impurities; for if it be strained through linen or muslin, it is mixed with hairs, which are extremely injurious to the grain. It may be added, that the apartment in which the fluid is poured on the plate should be perfectly still, and entirely free from dust; for if any fall on the plate while it is wet, the grain forms a white spot, which cannot be removed. Great care should be observed in cleaning the plate before the ground is laid on. This is done with a bit of rag and whitening. The smallest stain or particle of grease produces a streak or blemish in the grain. Still, however, with all the attention which can be employed, and with the utmost delicacy in the management, it is necessary to observe that the process is extremely precarious and uncertain; and even the most experienced artists find themselves frequently subject to very unaccountable accidents.

Artists have frequently complained of the inconvenience arising from the fumes which proceed from the action of the acid upon the copper when the plate is large. To remedy this inconvenience, the following arrangement, which seems well calculated to answer the purpose, was suggested by Mr Cornelius Varley, an artist who distinguished himself no less by his mechanical abilities than by the exquisite productions of his pencil in water colours: "Get a frame made of common deal, or any kind of wood, three or four inches deep, covered with a plate of glass, and open at one side; and let the side opposite to this have a round opening, communicating by means of a common iron pipe with the ash-pit of any little stove or other fire-place, shut up from all other access of air but what must pass through the pipe. It is obvious that any fumes rising from a copper-plate laid under such a frame will be carried backward into the iron pipe by the current of air required to maintain combustion in the stove, and will by this means be carried up the chimney, in place of being allowed to fly about in the apartment. The pipe may be very conveniently used by carrying it down through the table to the floor, and so along to the place where the chimney may chance to stand; and when the frame is not wanted, the pipe at one of the joinings may be made to answer the purpose of a hinge, by which to turn up the frame against the wall, where it may be secured, while out of use, by a button or any other contrivance."[1]

This method of engraving in aquatinta seems to be chiefly adapted for slight subjects in general, and for imitations of sketches and washed drawings. But for the production of prints from finished pictures it is by no means calculated, because it is not susceptible of that accuracy in the nice management of the tints which is necessary for this purpose. It is equally unsuitable for book plates, because, without retouching the plates, the number of impressions which can be thrown off is very small. On these accounts, therefore, it is to be considered as greatly inferior to the other modes of engraving. But as it is more expeditious, and may be attained with greater facility, it is undoubtedly useful when it is confined to those subjects for which it is peculiarly calculated. This rapidity of execution, however, and facility in acquiring the practice of the art, are followed with the unfortunate circumstance, that they favour the production of an indiscriminate multitude of prints, which, it is to be feared, may rather tend to vitiate than improve the public taste.

Engraving with the tool was the kind originally practised, and it is yet retained for many purposes. For though the manœuvre of etching be more easy, and other advantages attend it, yet where great regularity and exactness of the stroke or lines are required, the working with the graver is much more effectual; on which account it is more suitable to the precision necessary in the execution of portraits, as there every thing the most minute must be made out and expressed, according to the original subject, without any license to the fancy of the designer in deviating from it, or varying the effect either by that masterly negligence and simplicity in some parts, or those bold sallies of the imagination and hand in others, which give spirit and force to history painting.

The principal instruments used in engraving with the tool are, gravers, scrapers, a burnisher, an oil-stone, and a cushion for bearing the plates.

Gravers are made in several forms with respect to the points, some being square, others lozenge; the square graver being designed for cutting broad and deep, and the lozenge for more delicate and fine strokes and hatches. The most generally useful are those of a form between the square and lozenge; and they should be of a good length, small towards the point, but stronger upwards, that they may have strength enough to bear any stress which there may be occasion to lay upon them; for if they be too small and mounted high, they will bend, which frequently causes their breaking, especially if they be not employed for very small subjects.

The burnisher is used to assist in the engraving on some occasions, as well as to polish the plates. It is made of fine steel well polished. The burnisher is sometimes formed at one end, and a scraper on the other, each about an inch and a half long from the point; between them about four inches of the instrument is made round, and serves as a handle, and is thicker in the middle than at the necks, where the burnisher and scraper begin, which necks are only a quarter of an inch in diameter. The principal application of the burnisher in engraving, besides its use in polishing the plates, is to tone and harmonise the work, and to take out any scratches or accidental defacings that may happen to the plates during the engraving; or to lessen the effect of any parts that may be too strongly marked in the work, and require to be taken down.

A cushion, as it is called, is likewise sometimes used for supporting the plate in such a manner that it may be turned every way with ease. It is a bag of leather filled with sand, and should be of the size which will best suit the plates it is intended to bear. Cushions are round, and about nine inches over, and three inches in thickness.

The cushion, made as above directed, being laid on the table, the plate must be put upon it; and the graver being held in the hand in a proper manner, the point must be applied to the plate, and moved in the proper direction for producing the figures of the lines intended; observing, in forming lines, to hold the plate steady on the cushion, and where they are to be finer, to press more lightly, using greater force where they are to be broader and deeper. In making circular or other curve lines, hold your hand and graver steadily; and as you work, turn your plate upon the cushion against your graver, otherwise it will be impossible for you to make any circu-

[1] *Philosophical Magazine*, vol. xxiii. p. 137.

lar or curved line with that neatness and command of hand which by this means may be acquired. After part of the work is engraved, it is necessary to scrape it with the scraper or graver, passed in the most level direction over the plate, to take off the barb or roughness formed by the cutting of the graver; but great care must be taken not to incline the edge of the scraper or tool in such a manner that it may take the least hold of the copper, as it would otherwise produce scratches in the engraving; and, that the engraved work may be rendered more visible, it may afterwards be rubbed over with a roll of felt dipped in oil. In using the graver it is necessary to carry it as level as possible with the surface of the plate; for otherwise, if the fingers slip betwixt them, the line that will be produced, whether curved or straight, will become deeper and deeper in the progress of its formation, which entirely prevents strokes being made at one cut that will be fine at their extremities and larger in the middle, and occasions the necessity of retouching, to bring them to that state. For this reason it is very necessary for those who would learn to engrave in perfection, to endeavour, by frequent trials, to acquire the habit of making such strokes, both straight and curved, by lightening or sinking the graver with the hand, according to the particular occasion. If, after finishing the design, any scratches appear or any part of the engraving be falsely executed, such scratches or faulty parts must be taken out by the burnisher, and further polished, if necessary, by the above-mentioned roll.

The dry point, or needle, which has been of late much used in engraving, is a tool like an etching point, which being drawn hard on the copper, cuts a stroke and raises a burr; the burr is scraped off, and there remains a stroke more soft and delicate than can be produced in any other way.

Although the instruments for the use of the engraver above enumerated and described are very simple, yet we have thought it advisable to subjoin the following figures illustrative of their forms, and about half the dimensions of those employed.

Fig. 1.
Graver.

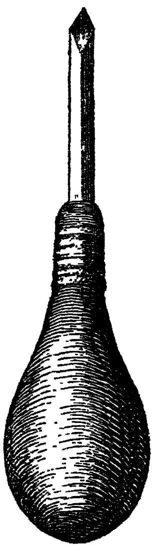

Fig. 2.
Dry Point, or Etching Needle.

Fig. 3.
Scraper.

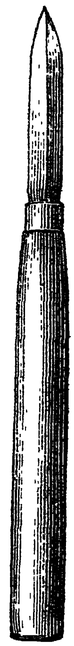

Fig. 4.
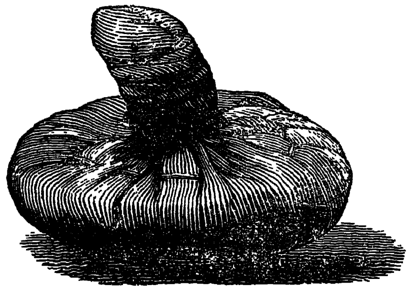
Burnisher.

Fig. 5.
Ball of Etching Ground, covered with silk.

Fig. 6.
Dauber, covered with silk, and stuffed with cotton or wool.



The plate is covered with etching ground in the following manner: Heat it upon a stove or otherwise till it melt the ground in the silk bag, fig. 5, which must be spread equally over the surface of the copper by means of the dauber, fig. 6. The ground is then to be moderately smoked all over with a candle, and when the plate is cold it is ready for use.

Etching ground is composed of virgin wax and asphaltum each two ounces, and of black and Burgundy pitch each half an ounce. Melt the wax and pitch in a new-glazed earthen pot, and add to them by degrees the asphaltum finely powdered; boil the whole until such time as, by taking a drop upon a plate, it will break when it is cold, on bending it double three or four times between the fingers. The ground, being sufficiently boiled, must be taken off the fire, and, being allowed to cool a little, must be poured into warm water if the weather be cold, or cold water if the contrary, in order that it may be the more easily worked with the hands; for it should be pulled a long time, to mix the ingredients more completely, when it may be divided into small balls for use. The fire must be moderate, for fear of burning the ground; and the ingredients must be stirred during the whole time of preparation, particularly when the asphaltum is being put in.

Wax for surrounding the plate in the process of biting in with aquafortis is made of one pound of Burgundy pitch or black pitch, and of bees' wax half a pound, melted over a slow fire. When melted, add about a gill of sweet oil, and when moderately hot, pour the whole into water, pull it well, and fashion it into balls for use.

In the conduct of the graver and dry point consists the whole art, for which there are no rules to be given, all depending on the habitude, disposition, and genius of the artist. However, besides the explanations already given, some general observations and directions may not be improper. As the principles of engraving are the same with those of painting, a person cannot expect to attain any considerable degree of perfection in this art who is

not a good master of design; and therefore he ought to be well acquainted with both perspective and drawing in general; for, by the proper degradations of strong and faint colours, he will be enabled to throw backwards the figures and other objects of the picture or design which he proposes to imitate, and which the painter often intrusts to the discretion of the engraver. In working, the strokes of the graver should never be crossed too much in a lozenge manner, particularly in the representation of flesh, because sharp angles produce the unpleasing effect of lattice-work, and take from the eye the repose which is agreeable to it in all kinds of picturesque designs; we should except the case of clouds, tempests, waves of the sea, the skins of hairy animals, or the leaves of trees, where this method of crossing may be admitted. But in avoiding the lozenge, it is not proper to get entirely into the square, which would give the work too much of the hardness of stone. In conducting the strokes, the action of the figures and of all their parts should be considered; it should be observed how they advance towards or recede from the eye; and the graver should be guided according to the risings or cavities of the muscles or folds, making the strokes wider and fainter in the light, and closer and firmer in the shades. Thus the figures will not appear jagged; and the hand should be lightened in such a manner that the outlines may be formed and terminated without being cut too hard. However, though the strokes break off where the muscle begins, yet they ought always to have a certain connection with each other, so that the first stroke may often serve by its return to make the second, which will show the freedom of the engraver.

In engraving the flesh, the effect may be produced in the lighter parts and middle tints by long pecks of the graver rather than by light lines, or by round dots, or by dots a little lengthened by the graver, or, best of all, by a judicious mixture of these together.

In engraving the hair and the beard, the engraver should begin his work by laying the principal lines, and sketching the chief shades, in a careless manner, or with a few strokes; after which he may finish it at leisure with finer and thinner strokes to the extremities. When architecture or sculpture is to be represented, except it be old and ruinous buildings, the work ought not to be made very black; because, as edifices are commonly constructed either of stone or white marble, the colour, being reflected on all sides, does not produce dark or brown shades, as in other substances.

In engraving cloths of different kinds, linen should be done with finer and closer lines than any other sorts, and be executed with single strokes. Woollen cloth should be engraved wide, in proportion to the coarseness or fineness of the stuff, and with only two strokes; and when the strokes are crossed, the second should be lighter than the first, and the third than the second. Shining stuffs, which are generally of silk or satin, and which produce flat or broken folds, should be engraved more clear and more straight than others, with one or two strokes, as their colours are bright or brown; and between the first strokes other smaller ones may be interlined. Velvet and plush are expressed in the same manner, and should always be interlined. Metals, as armour, &c. are also represented by interlining, or by clear single strokes. In architecture the strokes which form the rounding object should tend to the point of sight; and when whole columns occur, it is proper to produce the effect as much as possible by perpendicular strokes. If a cross stroke is put, it should be at right angles, and wider and thinner than the first stroke. In engraving mountains, the strokes ought to be frequently discontinued and broken for sharp and craggy objects; they should be straight, in the lozenge manner, and accompanied with long points or dots; and rocks should be represented by cross strokes more square and even. Objects which are distant towards the horizon should be kept very tender. Waters that are calm and still are best represented by strokes which are straight and parallel to the horizon, interlined with those that are finer, omitting such places as, in consequence of gleams of light, exhibit the shining appearance of water; and the form of objects reflected from the water at a small distance upon it, or upon the banks of the water, are expressed by the same strokes, retouched more strongly or faintly as occasion may require, and even by some that are perpendicular. For agitated waters, as the waves of the sea, the first strokes should follow the figure of the waves, and may be interlined, and the cross strokes, if any, ought to be very lozenge. In cascades the strokes should follow the fall, and may be interlined. In engraving clouds, the lines should sport, when they appear thick and agitated, in turning every way, according to their form and agitation. If the clouds are dark, so that two strokes are necessary, they should be crossed more lozenge than the figures, and the second strokes should be rather wider than the first. The flat clouds which are lost insensibly in the clear sky should be made by strokes parallel to the horizon, and a little waving; if second strokes are required, they should be more or less lozenge; and when they are brought to the extremity, the hand should be so lightened that they may form no outline. The flat and clear sky is represented by parallel and straight strokes, without the least turning. In landscapes, the trees, rocks, earth, and herbage, should be etched as much as possible; nothing should be left for the graver but perfecting, softening, and strengthening. The dry point produces an effect more delicate than the graver can, and may be used to very great advantage in linen, skies, distances, ice, and often in water, especially in small engravings. In most things it is proper to etch the shadows, only leaving the lighter tints for the dry point, graver, and other instruments.

Much excellence may be attained, and a great deal of time saved, by the process of rebiting, particularly in landscape. This process is effected in the following manner: When all the strokes have been laid in upon the portion of any subject to be rebit, the lines upon the plate should be very carefully cleaned out with turpentine and a piece of stale bread. It is then to be heated, and the dabber, with a moderate portion of etching ground, applied dexterously to the surface, care being taken, however, not to permit the ground to sink into the lines, but only to cover the intermediate surface effectually. The aquafortis is now to be applied, and the lines bit down or corroded to the depth required. This process is, comparatively speaking, of recent invention, and was wont to be esteemed precarious and difficult in the management; but a little experience, and the great demand for illustrated works of late years, have been the means of rendering this, as well as other matters of detail in the engraver's art, much more certain.

To imitate *chalk drawings*, a mixture of varied and irregular dots are used, made more or less soft, so as to resemble the grain produced by the chalks on paper. Every stroke of the chalks on paper may be considered as an infinite number of adjoining points, which are the small eminences of the grain of the paper touched by the chalk in passing over it. When the copper-plate has been properly prepared with etching ground, as in the common method of engraving, the drawing to be imitated may be counterproved on the ground of the plate. If this cannot be conveniently done, black-lead pencil or red chalk must be applied to varnished or oiled paper, and this chalk or pencil transmitted to the ground. The outlines of the

object must be formed in the etching by points, whose magnitude and distance must be determined by the quality of the strokes in the original drawing. The artist may be provided with pointed instruments or needles of various sizes, with single or double points. In forming the light and shade, he should distinguish between those hatches which serve to express the perspective of the object, and those which form the ground of it. The principal hatches should be more strongly marked; the middle tints, if etched, should be marked lightly, or they may be left till the varnish is taken off, and be perfected with a greater degree of softness by needles, or the point of the graver, as the original may require. There is nothing peculiar in the method of applying the aquafortis in this kind of engraving; but it may be observed that it should not be left so long as to corrode too much the lighter parts. If the light parts are sufficiently corroded, they may be stopped up with turpentine varnish and lampblack mixed together, and the aquafortis may be applied again to the stronger parts; for it will be no detriment to them, if the points which compose the shade burst into one another, provided the extreme be avoided. When the work of the aquafortis is finished, and the varnish taken off the copper, it will be necessary in the softest parts, such as the flesh, to interstipple with proper points, as an effect will be thus produced more delicate than it is possible to attain with the aquafortis only; and the strongest shades will require additional strength to be given them with small strokes of the graver. Drawings made with chalks of different colours may be imitated in this manner, if a plate be provided for every colour. This method of engraving is intended to form a kind of deception, so that the connoisseur may not be able, on the first inspection, to distinguish between the original drawing and the engraving made in imitation of it; and it is extremely useful, as it serves to multiply copies of drawings left by those masters who excelled in the use of chalks, and thus to form and improve young artists, who could not have access to the originals in the practice of drawing.

To this account of the history and practice of the art of engraving we shall annex the following ingenious observations by an eminent artist.[1] We present them to our readers without alteration or abridgment.

On the linear art in general.

"When compared with painting, the art of engraving is but a recent invention, being coeval only with that of printing; and, like that noble art, it possesses not only a similar, but a greater power of multiplying and extending the productions of genius over the world, for its language is universally understood.

"It would have been well for the art if it could boast of a more remote date, as we might then have had many more of the finest designs of the first painters of antiquity, now doomed to oblivion, saved from the rude ravages of time.

"But this invention seemed to be reserved for the fourteenth century, and its improvements for the age of Louis XIV.; an age in which a number of artists, who may be said to have invigorated the art and invested it with beauty, arose both in France and Italy.

"Lines, in the first state of the art, like every other pursuit whose excellence is progressive, were comparatively rude and unmeaning, and had nothing more to recommend them than merely representing a particular sort of markings, or slight hatchings with the pen, without any other apparent degree of execution or expression; although it is our pride to acknowledge that it has been not a little beholden to the elegant etchings of the great masters in painting, as well as to their drawings in pen and ink in its early stages, by which means an eminent degree of taste was introduced into the art, particularly in the department of linear disposition; amongst those, the drawing of a Raffaelle, Michel Angelo, and the learned Da Vinci, some of which we have occasionally seen and admired. Some by Da Vinci were hatched in a square but delicate manner, with a white fluid, on dark-coloured paper. Those of Michel Angelo and Raffaelle inclined more to the lozenge, in black or brown ink. They even carried this style of hatching with the pencil into their pictures, some of which adorn the Vatican; and in the famous cartoons in the Royal collection by Raffaelle. Baccio Bandinelli generally hatched his lines in one direction, particularly a Taking down from the Cross, which was sold in London at the sale of the late Sir Joshua Reynolds' drawings. Vicenzio Dante hatched in a similar way about the year 1550. Julio Romano used also to draw in this style with the pen, several of which are still to be found in the most select cabinets of men of taste; and for near a century and a half after the invention of etching, it is rare to mention a painter of eminence who was distinguished in drawings, who did not annex this art to that of painting. But with the application of the burin the art has been gradually improving till the present period. Linear[2] engraving is nothing more than drawing elegantly on copper. It became more studied as it was found capable of representing the various appearances of nature. The texture or surface of objects became proportionally discriminated by such peculiar modifications of the line as seemed most suitable to the subject represented, although, at the same time, it rendered it much more arduous in the execution. Hence arose that diversity of style, and that scope for succeeding excellence, which, by combining elegance with simplicity and beauty, distinguished those artists who have been most conspicuous in its improvement.

"It has been said that we are indebted for the origin of this art to an ingenious Florentine, Masso Finiguerra the sculptor. He was succeeded by a number of other ingenious men, among whom we rank Botticelli, Andrea Mantigna, and other able designers; and in Germany, Albert Durer, Aldgrave, and Lucas van Leyden, who severally contributed their labours. But in the fifteenth century the works of the divine Raffaelle began to be multiplied by the correct graver of Marco Antonio, an artist whose prints were the delight of that great painter. Antonio had many imitators, but none who equalled him for justness of contour, for which his works will be ever highly appreciated among the early productions of the art. Having had occasion to mention a few of the principal artists who reared the scaffolding of this elegant art, we shall proceed to those who have so much distinguished themselves in finishing the superstructure. Among those, Augustino of Venice began to introduce a better disposition of line in his shades, as well as the ingenious Bolognese, Augustino Caracci; whilst Egedius Sadelaer displayed no less zeal in Germany. In the sixteenth century the art displayed still more vigour and taste, and seemed to have but little more wanting; for all that meagre dryness of line began to disappear, which so manifestly marks the early works of Il Tedesco, Aldegraff, and other artists of a former period. Their works became consequent-

[1] Francis Legat, Esq. historical engraver to George IV. when Prince of Wales, and F. A. S. E.

[2] The author has taken the liberty of adopting here the word *linear*, from its strict analogy to this mode of engraving, and with the approbation of some of the first professors, both in painting and engraving.

ly more rich in style, by embracing the best productions of the pencil; and as they were applied to a greater number of ideas, they became still more interesting and successful.

"Patrons were numerous and liberal; and it is but proper to remark, that the various artists, on their part actuated by a becoming zeal which was highly creditable to themselves, were indefatigable. This is a circumstance not less worthy of imitation than the many admirable monuments of the art which they produced. Few but admired the works of Masson, Poilly, Nantueil, and Rousselet; and some time after the death of the ingenious Cornelius Bloemart, who had given a grace to his lines hitherto unknown at Rome, the matchless Audran and Edelinck displayed their excellent productions at Paris. But arts are liable to fluctuate; and when the art of engraving began to decline abroad, it gradually displayed a high degree of lustre in our own country; and the variety of styles which has since sprung from the original manner of engraving, shall be the subject of the following sketch.

"We shall, therefore, treat more particularly of the disposition of the lines, and their consequent effects, distinguished by the terms *linear expression, imitation, disposition,* and *harmony;* with a strict investigation of the first and most approved subjects, either in etching or engraving, and of their essential beauties, as far as they may tend to illustrate the subject.

"As the great object of this mode of engraving is to adopt those lines the most expressive of the form and character of whatever happens to be represented, it is necessary to begin by maturely investigating not only the action, but the cause and correspondent effects, of the original picture, in order that the artist may avail himself of all that is most beautiful in his translation, and efficient in the aggregate, either with respect to the expression, spirit, or sentiment.

On linear expression and disposition.

"When historical subjects consist of several figures where there is generally a variety of draperies, some of them appearing thick and cumbersome, others more thin and flexible, sitting close and elegant on the limbs, being composed of a finer texture or thread; the coarser stuffs are consequently more effectually represented by a bolder line, as the thinner sort, by the application of a fine line, gives a more lively representation; a discrimination which has been observed of late by the most approved modern artists in linear engraving. Observations of this description, when treated in a liberal manner, not only superadd a degree of truth, but even render the subjects sweeter to the eye of fancy. In the early stages of the art some excellent artists have been led into particular and limited systems. In the works of such as have affected to describe every subject in the same line indiscriminately, even the arms of the most delicate women are often engraven as if perfectly polished, by approaching to a metallic appearance, a mode not uncommon among the second or third class of artists about the beginning of the last century; by which manner all that softness and delicacy was neglected which is so happily effected in the linear productions of Strange, Bartolozzi, Morgan, Sharp, Heath, and others. Those who are acquainted with the works of the ingenious Chaffard, must with pleasure have perceived in his foliage how even the texture of flowers is imitated from the delicate line-like fibres of which they are composed, issuing from the stem and spreading their silken beauties to the sun; and in this class of imitation, the clear transparency of glass, the rough texture of woollen, the thinness of lawn, the flickerings of satin, or the lightnings of steel, as well as the rude rock, the lucid lake, or the flashing of the torrent, are all admirably adapted to linear effect by the almost infinite diversity in their construction and general constituent principles, strictly observing on what laws the beauty of lines consists, by ever keeping in view the due balance of taste, and a noble simplicity of style throughout. It is the business of the skilful artist to overpower and subdue the difficulties in his profession; for no excellence in art is of cheap or vulgar acquisition. Let it be remembered, that with forming steel even the enchanting graces of the Venus de' Medicis were hewn from a rock, and the almost breathing Apollo from a block of Parian stone.

"An elegant English poet, in a critical essay on poetry, observes that the sound should seem an echo to the sense; so should the lines in a fine print seem to harmonize with the subject, by flowing with the external cast of the features, and the predominant passion expressed in the original picture; for the same character and disposition of the lines that suit the action of the muscles in one passion, will be found to appear more vacant and less expressive when applied to others, however graceful they may appear.

"As this is a point of view to which the art has never yet been fully extended, perhaps it may meet with some degree of attention, as it will be found of utility in forming a principle respecting disposition, more particularly in historical subjects, where the passions are required to be nicely expressed; and although it may admit of some slight exceptions, it is a principle that will in general be found to be true.

"For example, let it be supposed that the passion of the figure represented is that of joy, the lines should seem to expand and swell, with every acting muscle, in the most delicate manner possible.

"But, on the contrary, if the subject displays deep sorrow, they should rather incline downward, partaking somewhat of the half straight, seeming to act apparently in perfect unison and conformity with the features of the face, with all due subordination to the general effect of light and shadow.

"Various observations may be made in this manner on the principal passions expressed in the human countenance, which are but few comparatively, even from the slightest movement to the boldest action. We often find, on examining the works of those masters who are not so conspicuous for great clearness of execution, that they have been occupied by the disposition and energy of the lines; as in the magnificent and masterly prints of the battles of Alexander, from the pictures of Charles le Brun, engraved by Gerrard Audran, where the executive department is no less conspicuous from the burin of the Chevalier Edelinck in the fine print of the tent of Darius; whilst Audran displays the true spirit of art, but rarely avails himself of much of the mechanical principles. The field and tumult of battle seemed admirably calculated to call forth his rapid powers, particularly in works of magnitude.

"The less active scenery of the tent of Darius was well adapted to the splendid talents of Edelinck, who was admirably qualified to display subjects of this nature. This is sufficiently obvious from the beautiful and interesting group of the queen mother, and her illustrious family, kneeling at the feet of the conqueror; his impressive print of the Magdalene, or his most admirable portraits of the dignified clergy, distinguished authors, and eminent artists. These, in point of engraving, are no less remarkable for taste in the execution, than for truth and nature in expression.

"In one of the battles of Alexander, the group where Porus is wounded and supported by the soldiers, the rough discrimination of line finely accords with that bold deportment of character in the grim visage of that gigantic

prince, whilst a more delicate line marks the youthful countenance of Alexander; a discrimination which is totally lost in the large Dutch copy by De Vos.

"In the same print the figures of Alexander and Clytus are finely relieved from the distant scenery by the varied description of engraving on their armour, drapery, and horses. The latter are managed with such freedom and spirit, that it is difficult to say whether the horses or figures teem the most with masterly execution; particularly the white war-horse on the right extremity of the print.[1]

"Had Audran superadded a still greater portion of the delicacy and clearness of handling so conspicuous in Edelinck and other eminent artists since that period, it would undoubtedly have given an additional beauty to his other transcendent acquisitions; namely, the vast spirit of his lines, and power in drawing.

"But it is seldom the lot of an individual to combine every excellence. Arts too have their infancy, for they generally require the labour of ages to bring them to maturity and perfection; and it yet remained to unite and ameliorate the polish of Edelinck, to the spirited style of Audran. Without prejudice or partiality, a considerable degree of this excellence will be found in the best works of British art, as we shall hereafter exemplify.

"Another fine specimen of linear engraving, and of a different class, is the celebrated storm of Balechow, from a picture of the famous Vernet. In this print he has transmitted with the graver a certain fluidity and action in representing the liquid element, to which the art had never before attained. To a grandeur of style in the bold swelling of the waves he has superadded the utmost transparency of line; at the same time having attended to all that light restless spray which seems sporting to the gales as they roll along. In a fanciful mood one might almost imagine they heard the motion of the water; so finely did this discriminating artist translate this admirable picture.

"When we consider the period in which this distinguished work was engraved, and that little or nothing had been previously done in that department of a similar excellence, it is hoped it will be a sufficient apology for the degree of admiration here expressed; for, as Lord Verulam truly observes, "we are too prone to pass those ladders by which the arts are reared, and generally reflect all the merit to the last new performer." We have already observed, they are seldom reared with rapidity, and oftentimes that which is considered an invention is only a long succession of trials and experiments, which have gradually followed each other, and ought rather to be considered as a series of human mind than the knowledge of an individual, being the works of ages. In any point of view, the present subject will ever be considered as a high improvement and an elegant acquisition in the annals of the linear art. But in historical subjects this artist is by no means equal in point of taste or discrimination. His print of St Genevive undoubtedly ranks high in the first classes of engraving. Had his taste in other respects been equal to his powerful clearness of execution, it would have been almost unparalleled; but it betrays a want of that essential, even in his mode of thinking. Patience and labour are everywhere too prevalent. It remained for Woollet to excel both in figures and landscapes.

"In the various styles and modifications of this expressive art, from the neat to the feeble, and from the bold to the extravagant, taste stands sole arbitress; in brief, it is she who distributes variety with spirit, and conceals the appearance of intricacy and labour; who, by a due modification of line, unites clearness to softness, arresting the hand of the skilful artist from every effort inconsistent with her powers; producing at once to the mind all that agreeable finished combination or harmony which ever accompanies and constitutes the perfection of true art.

"In the execution of subjects of imagination, there is a perpetual scope for calling forth the fancy of the engraver, as the various combinations of lines are inexhaustible, uncommon effects, such as aerial spirits, or celestial beings blended with the light, or ghosts commingled with the gloom, or fairy elves by moonlight, who trip the sands, and yet no footing seen; or wood nymphs laving their taper limbs in the limpid element. Such subjects, in point of style, depend entirely upon the beauty, lightness, and transparency of execution; for those that are merely ornamental or grotesque demand a style of a different cast from that of the serious or historical, as they require a less degree of truth even from the burin. In these cases the style may be as capricious as the subjects. Those of Raffaelle, in the Vatican, display an uncommon degree of taste, and particularly in the elegant flow of line with which they are composed.

"In all works of taste and genius, those which may appear the most simple at a transient glance, will be often found to contain the most art on a more mature investigation. The first impression may strike the fancy, but the second generally calls up the discriminating powers of the judgment.

"Arts generally rise in our esteem according to the degree of exertion of the mental powers which they require; and, as lines are capable of various styles, those which are most congenial to the subject represented ought to be adhered to in preference to every other consideration. Teniers and Gerrard Douw demand all the fidelity and delicacy of the burin in describing the various draperies and individualities which belong to that class of painting; but, in proportion as the contour is composed of fewer parts, and the forms more full and elegant, the beautiful flowing qualities of the graver are increased, and its lines glide more gracefully over the figures, as may be found in the works of Strange and others, from Guido and Correggio. This distinction will not appear so obvious on a superficial view of the art. But, on a due investigation, it will be found, that not only a different modification of lines is necessary to the various classes of painting, but that even a different description of style is requisite to characterize some of the masters in each particular class, from the sublime and elevated figures of a Raffaelle and Michel Angelo, to the simple cottagers of Adrian Ostade.

"When we take a more comprehensive view of the art, we often find, that the styles which are adopted in the different countries in Europe by the artists where the art has in any degree been cultivated, are generally regulated by the modes of painting, drawing, and even the colouring respectively in each, whether historical, portrait, or landscape, and is proportionably appreciated according to the effective beauty and elegance of the execution.

"It is not improbable that the clear mode, which at present constitutes the modern German school, is a refinement on the simple style of Cornelius Bloemart.

"In Italy, Jachimo Frey, that astonishing Swiss, from his masterly expertness in drawing, and a rapid use of the etching steel and the nitre, almost produced an entire revolution in the art. The unprecedented richness and ease, the freedom and energy of his style, and the number and magnitude of his works, attracted all Italy, and tended

[1] Whenever M. Bartolozzi happened to speak of these prints, he always expressed himself with a great degree of enthusiasm, thinking himself extremely fortunate in having works of such excellence in his possession.

greatly to improve the Roman school. About the year 1672 we find him working jointly with the nervous Dorigny Frezza, and Vanauden Aird. From this source we can perceive the style of Wagner, of Cars in France, and various masters now living; namely, Francisco Bartolozzi, Giovanni Volpato, Dominico Cunigo, and some of the early works of the excellent Raphael Morghen.

"In many instances Frey indicates, that if he had considered it of sufficient consequence to the art, he could have engraved with more clearness, particularly by his curious copy, from the celebrated print by Edelinck, of the Madona and Child, with St John and Angels, from Raffaelle; and, although but an imitation of another style, tends to show the versatility of his talents, when the judgment is for a while suspended to know which is the original. We find a performance of Frey's, entitled *La Charité Humaine*, dated 1723; a print was afterwards engraved from the same subject at Paris by Daulle, dated 1763, in which he has rather been too profuse in the more mechanical part of the art, and destitute of that ardour which a well engraved work should not only inspire but maintain.

"It is not enough for lines to be only well disposed, but also full of expression; neither is it enough for a line to be only clearly cut, but it must also be free; for in a certain free light spirited lines convey an idea of animation, and are suited to subjects of that description; while the long, sweeping, and bold lines are better adapted to the solemn and majestic productions of the pencil.

"A fine print, like a miniature picture, ought to be viewed near the eye; as in itself, from the nature of the art, will be found a due subordination of effect, ever receding, from the bold and articulated lines in the fore ground, to those which are more evanescent and remote.

"The graceful birch, the mountain ash, and the oak, have each their peculiar bark and texture; and these, when freely indicated, stamp their mark and character most completely to the eye. Much of this, as has been formerly mentioned, depends upon, and is regulated by, the peculiar style of the picture and the skill of the engraver.

"As lines seem to partake of motion, in proportion as they deviate in gentle bendings from the straight and precise; even so also in the motion of water seemingly increased, whether they undulate with the simplest wave, or swell with the fierce and tempest-curled surge. This character is sufficiently illustrated in the works of Balechow and Woollet.

"In the late Mr Brown's large print of St John preaching in the wilderness, no engraver has ever more fully displayed the true spirit of Salvator Rosa, particularly in the original mode of treating the rocks, and the bold style of the surrounding scenery; in short, in the aggregate it is a chef d'œuvre unparalleled in any country. This is freely acknowledged, not only by every man of taste, but by the first landscape engravers.

"But Brown was perhaps less happy in the companion to the above, from the celebrated Both, by adapting a similar mode to that finished and delicate painter. For the style should ever vary with the subject.

> Whate'er Lorrain light touched with softening hue,
> Or savage Rosa dash'd, or learned Poussin drew.

"His admirable etchings of the cottager and its companion, and the Celadon and Amelia, are fine specimens of his discriminating powers, and characterized with so near an approach to truth, that we cannot help exclaiming with the poet,

> He sees no other, nature's self who sees.

"The engraving of the above subjects was finished by the matchless Woollet with the same happy taste. And it must be acknowledged that it is but seldom that we see so many excellencies united; for it is equally rare to see the finest engraving united to the finest drawing, as to find it in painting combined with the choicest colouring; yet each have their decided fascinations in the gallery, the cabinet, or the portfolio.

"Woollet, whose works abound with nerve and intelligence in point of character, his style of landscape is delightfully descriptive; whether rocks, water, trees, or sky; as the Niobe, the Ceyx and Alcyone, and other masterpieces from the great Wilson, evince. In the winter scene from Smith of Chichester he has admirably contrived to convey the effect of the drifted snow by delicate dotting; and with no less precision he has described the transparent ice with clear lines. Of trees, he was the first that ever faithfully characterized the graceful larch; as may be seen in his views of the noblemen's seats. In the print of the fishery he is indebted to the masterly etching of John Brown, particularly the shipping, in which there is perhaps no subject more articulate and perspicuous. The engraving of this subject is finished by himself. In his figures he was the founder of a style most happily adapted for modern dresses and historical portraiture; a style in which he moved with unrivalled reputation. His print of the death of General Wolf, painted by Mr West, is an admirable example, and does honour to the British nation. It occupied him no less than four years. The print of the battle at La Hogue is another fine specimen of his knowledge of linear discrimination. In short, when we consider the talents of this artist, it is difficult to decide whether he most excelled in modern history or landscape. The art has to regret that he, who was so eminently qualified to adorn any line of the profession, has left no works in ancient history. We have little doubt, from his knowledge, and a real love of the art, he would have left a sufficient monument in that department also for the pleasure and contemplation of the real connoisseur and of posterity. Engraving in this country sustained a heavy loss when he died; and if the death of so excellent an artist may be considered as a public loss, it is certainly the more felt with respect to Woollet, who died while he was yet improving in that excellence.[1]

"Chattelaine has been termed a mannerist in his drawings, but he must certainly be allowed to be an excellent one; his etchings are variety itself. Perhaps in the department of etching no artist has so happily translated the pictures of Claude de Lorraine as Francis Vivares; that is, with respect to aerial perspective, the peculiar characteristic of Claude. But his merits are not confined to this master alone; for he followed Ruysdale, Berghem, Gainsborough, and Cuyp, with great success. He has such a free delivery of style, that almost every one who examines his works is irresistibly impressed with an idea of performing the very same. Few artists, it has been mentioned, have excelled in the etching department. We cannot, however, omit the name of Peranezzi; who, to originality of style, which is apparently spontaneous, joins a certain grandeur which had never been surpassed. He has transmitted to posterity so spirited a representation of the Greek and Roman edifices and ruins, that travellers have often confessed that they have raised their ideas beyond the magnitude of the superstructures themselves. It is certain that in works of this stupendous nature, a degree of ruggedness in the execution corresponds with the sublimity of the subjects, and thus produces a still great-

[1] Although we are now contemplating linear engraving, it is but proper here to observe, that chalk engraving, mezzotinto, and aquatinta, have also made ample improvements in this country in their various styles of excellence.

Engraving. er power over the mind than if they had been more polished. Some have censured his figures, and not without cause. This defect has been ingeniously palliated by an excellent artist, M. Bartolozzi. "For," said he, "if the purchasers of the works of Peranezzi get so much for their money in the building way, the figures may be supposed to be given for nothing." Doubtless those vast piles of perishing grandeur were never more judiciously presented to the eye than by this astonishing artist, or better calculated to affect the mind by calling forth its most sublime ideas.

"We have another striking instance of spirited etching in a different pursuit of the art, in the works of Ridinger, a name which brings along with it all the savage scenery of nature.

> Assembling wolves in raging troops descend..........
> They fasten on the steed, and pierce his mighty heart.

For we shall ever find some peculiar beauty to admire, even in the slightest productions of genius, as well as in the most perfect productions of the burin.

"There are few artists who do not regret that etching was unknown to Bolswert, who has done so much without its aid; from which we may easily suppose how much more he could have effected with this charming acquisition. For the truth of this remark we may appeal to his landscapes from Rubens, his animated portraits from Vandyke, and his productions from the Flemish school of history, particularly his large print of the taking down from the cross, from Rubens.

"There is a fine instance of linear effect in a print of a Flemish conversation piece by Wille. One of the figures is drinking out of a glass, and the artist has most deceptively described the texture of the drinker's face through the glass. In the same print a female figure shows great skill in this way; even the floor is characterized by lines; and the whole strongly marks the most proper mode of treating subjects of a mere local nature. The beautiful print of the *Petit Physicien* is also an admirable imitation, particularly the little pellucid globule which has just mounted from the shell. When lines are engraved in a square acute method of crossing, they generally convey the idea of hardness to the subject represented. The scientific Picart seems to have been so much aware of this, that in a print of his engraving of a large marble group of horses, from the animated chisel of Perriere, he adopted this style in order to heighten the imitation.

"Mason's print of Marshal Harcourt is one of the many fine efforts of portrait engraving; and although it was executed at an early period of the art, it abounds with no small degree of taste. The celebrated print (called the table-cloth), from Titian, of the Last Supper, also contains a considerable degree of linear discrimination, although he sometimes carries it to affectation. He is rather singular in his mode of engraving hair. Yet the portraits of Marshal Harcourt and Brisasiere the secretary may be deemed exceptions.

"While, by the magic of his tooling, he is too apt at times to give his works indiscriminately the appearance of bronze; and we frequently find the same in the figures of Balechow; but it seems to have been reserved for Strange to give the softness of carnation to copper, and to Woollet to give force and clearness with discriminating taste; Bartolozzi in his lines, elegance, delicacy, and drawing; while the works of Audran teem with boldness and simplicity. In the prints of Sir Robert Strange, the greatest excellence is perhaps his rich and harmonious tones, as well as the whole effect, which is supported by an expressive style, which he seems in a great measure to have invented for his most favourite painters, Correggio, Titian, Guido, and Guerchino. The softness, the gusto, and the flowing draperies in the works of these masters, were his delight. His sleeping Cupid from Guido, and the prints of the Venus and Danaë from Titian, will ever be esteemed as *chef d'œuvres* in the linear art." Engraving

Having thus attempted to fulfil our original intention of discriminating the most expressive combinations of lines, and of analyzing and illustrating their various powers and effects in engraving, we shall now conclude these observations; and if, from the nature of the subject, and from the limits of the sketch, we have failed in marking every brilliant star in the galaxy of the art, it must at least be acknowledged that we have not omitted some of those of the first magnitude.

Engraving *upon Steel.* On the first discovery of the art of printing from engraved metals, experiments would most probably be made with a view of ascertaining the fittest metal for the purpose. Indeed it is known that copper, tin, and silver were employed by the early artists; and there are some prints by Albert Durer which are considered as impressions from plates engraved or etched on steel. In the collection of Albert Durer's prints in the British Museum there are five of these prints, the chief of which are, *Christ in the Garden*, a print six inches by eight and a half, dated 1515; the *Lady and the Monster*, twelve inches by eight and a fourth, dated 1516; and the *Canon*, twelve and three fourth inches by eight and a half, dated 1518.

But, for the usual purposes of engraving, copper has, till within a few years, been supposed to have some advantages, which have led to its being nearly always employed in preference to other metals; and in one instance only have we found that steel-plate was used for engraving upon in this country, before the late attempts to prevent the forgery of bank-notes. The plate we allude to is the Ceiling of the Star Chamber, in the *Topographical Illustrations of Westminster*, engraved by Mr J. T. Smith in 1805.

The great expense of renewing plates for bank-notes, when any superior engraving is introduced for rendering imitation difficult, suggested the idea of employing a harder material than copper to engrave upon. Steel-plate was tried, and found capable of affording from twenty to thirty times the number of impressions that could be obtained from a plate of copper, whilst it was not much more difficult to engrave upon. The advantages derived from employing steel were first made public in this country in 1818, by the inquiry respecting the prevention of forgery, instituted by the Society for the Encouragement of Arts in London, when a specimen of engraving on soft steel was presented to the society by the late Mr Charles Warren; and it appeared from evidence collected by the committee, that notes with ornamental borders, printed from steel-plates, were then in use in America. Soon after this period Messrs Perkins and Fairman from America, in conjunction with Mr Heath, an eminent engraver of London, formed an establishment for printing notes and other engravings from steel blocks.

The methods of engraving on steel now universally adopted are similar to those employed in engraving on copper; differing only as far as was necessary on account of the nature of the material and the process of hardening the plates in use in the earlier stages of this invention. In addition to these methods, Perkins, Fairman, and Heath employ a mechanical process for increasing the number of steel plates. They first make the engraving on a thick plate of soft steel; the plate is then hardened, and the impression is transferred, in a spring press, to the surface of a soft steel cylinder, by rolling the cylinder repeatedly to and fro on the engraved plate, under a very considerable pressure. The transfer thus ob-

tained is in relief; and the cylinder being hardened, it is made, by the same spring press, to repeat as many impressions as may be desired on soft steel, or on copperplates, for the purpose of printing from. They usually impress steel blocks, each of which will afford several thousand impressions; and when the cylinder becomes worn by transferring, a new one may be impressed from the original engraving; and, consequently, an inconceivable number of plates may be obtained from one original plate.

It ought, however, to be remarked, that an engraving cannot be transferred from steel to steel without injury; and that the injury will be greater in proportion to the delicacy of the work. Indeed, where engravings are to be considered as works of art, it will always be preferable to engrave or etch on softened steel, and print from it without hardening. A sufficient quantity of impressions may thus be obtained, and of a superior kind; because steel being harder and more compact than copper, it is consequently less worn by the process of wiping off the printing ink either with the cloth or the hand.[1] But the power of transferring is of great value in all cases where a great number of impressions is the chief object desired, as in notes, plates for school-books, ornamental borders for pottery, labels, and the like.

In preparing steel-plates, either for engraving or etching, the surface should be well polished, so as to render it compact, of an equable degree of hardness, and perfectly smooth. The same tools are used as for copper, but they should be of the kind of steel which is endowed with the greatest degree of toughness. When a plate is to be etched, the point which removes the varnish should be sufficiently hard to penetrate the polish on the surface of the plate; the acid will then bite more freely, and to a greater depth, without spreading so as to produce a broad and shallow line. A point of diamond is, we believe, sometimes employed, particularly where the lines are drawn with the *ruling-machine* invented by Mr Wilson Lowry, the founder of a new school of engraving, which has been of infinite use in diffusing correct taste in architecture and sound knowledge in mechanics. The same ingenious artist observed, in the first etchings on steel, that the lines were broad without depth; and, in consequence, tried to find a *menstruum* which would answer the purpose better than the common acids. In this he perfectly succeeded, and was enabled to bite the lines deep, and yet preserve the desired degree of fineness.

Of the common acids, diluted muriatic acid seems to answer best; but diluted nitric and nitrous acids produce nearly the same effect.

When the graver is to be much employed on a plate, it should be annealed, in order to render it uniformly soft. The plate, after being engraved, may be hardened most effectually, and with the least injury to the engraving, or risk of warping the plate, by heating it in a metallic bath, and quenching the whole in a cooling fluid. A bath of the fusible alloy of lead, tin, and bismuth, which Dr Wollaston proposed for hardening delicate steel-work, will perhaps answer better than any other. (See CUTLERY.) It will always be an advantage to employ a perfectly fluid medium for cooling; and we have reason to conclude, from some hasty experiments, that water heated to its boiling-point is better than cold water for cooling steel. The quick abstraction of heat, by converting water into steam, seems to have more effect than the mere cooling power of a large body of cold water. Plates to be hardened should be about half an inch thick.

Being engaged to get up about 100,000 one-pound notes, and not having had time to case-harden the plate, the writer was enabled to produce the quantity by means of partially repairing it; and upon mentioning to Sir David Brewster the circumstance, he accounted for it on the ground that steel, when soft, is tougher and closer in the grain than when hardened.

Mezzotinto engraving on steel is also found to answer well; and upon that metal some very fine prints have lately been done; and the great number of impressions which a steel plate affords will cause this beautiful style of engraving to be more generally cultivated.

As printing from engraved steel is now much used as a means of preventing forgery, we shall close this article with a few remarks on that subject. It appears to us that there should be nothing complex in the figures which are selected for the engraving; their excellence should consist in the perfect evenness and parallelism of lines, whether straight or curved; but curved lines of difficult kinds should be preferred. Many crossings render a pattern intricate and confused; they distract the attention and dazzle the sight. Wavy patterns, with scattered lights, have the same effect. In such cases it is difficult to compare one specimen with another, and a general imitation is not so easily detected. It will be desirable to combine the work of an artist with that of a mechanical engraver; and in such cases the subject should be of sufficient size to allow of its being distinctly made out, because it will increase the difficulty of imitation. Where the circulation of notes is limited, good engraving on the note will be some check upon forgery; but the notes of different banks should be made as distinct as possible, instead of the same work being introduced in different notes; as may easily be done with steel cylinders. Where a whole empire is served with one kind of notes, the temptation to forge is so great that it cannot perhaps be altogether prevented; and, therefore, whilst every proper expedient should be used to increase the difficulty of forgery, no apparent difficulty of copying should render bankers and others less on their guard against it.[2]

The invention of the ruling machine by Lowry was sure to produce other methods of shortening the labour incident on engraving entirely by the hand; and thus we have the ingenious modes practised by the Americans in their bank-notes, bills, &c., and also the process known by the name of anaglyptography. The public are in possession of some very beautiful copies both of ancient and modern art—the work of that machine—in what may be called *basso-relievo;* but after the death of the inventor, Mr Bate, the art was taken up by Mr Stokes, who carried the invention to such excellence as to produce copies from entire statues.

Stokes's engraving machine is constructed to give a perspective likeness of the statue operated on. It consists of two parts, which are fixed on a stand. The first part is what is called a section apparatus; and the second part a projection rod. The section apparatus consists of two conically-shaped arms, jointed together and balanced on an axis—this axis being parallel to the axis by which the conical arms are jointed together—thus compelling the end of the smallest arm attached to a sliding frame to move in a plane at right angles to the axis on which they are suspended; thereby giving the plane of the sections on the

---

[1] A steel-plate which had not been hardened has been known to afford 95,000 impressions without material injury.

[2] At the ordinary meeting of the Society of Arts, held December 1854, a paper was read "On the New Bank of England Note, and the substitution of surface-printing from electrotypes for the ordinary copperplate-printing." Mr Smee stated that he had proposed to the Bank a system whereby surface-printing from electrotype should be substituted for the plate-printing, and that, with Mr Hensman and Mr Coe, typography had been brought into successful operation for all the numerous forms of notes and checks required. The originals of the devices and letters were never employed for printing, but are simply used as mould-makers, from which electro-casts are taken by the use of the ordinary Smee's battery and precipitating trough. The bank-notes, by this system, are printed at a steam-press, constructed by Napier; and no less than 3000 notes are printed per hour. By this system the most perfect identity would be insured. This method has now been put in operation at the Bank of England.

statue an inclination of 45 degrees to the plane of the drawing board on which the copy is to be made, and always parallel to itself whilst it is moved up and down a prism-shaped pillar, which is accurately graduated by a dividing apparatus.

The projection rod is a light hollow arm, which is strengthened by stays and tension wires, and balanced by a universal joint to a fulcrum firmly fixed on the stand. At one end of the rod is a slider, moving freely between four friction rollers, the slider being also attached to the section apparatus by a universal joint; while at the other end of the rod is the etching point, working against a vertical drawing board.

When the machine is to be used, the universal joint on which the projection is balanced is adjusted to the point of view at which it is determined previously the copy of the statue shall be made.

The section apparatus being raised sufficiently high, the operator takes the slider of the projection rod, and presses it lightly against the statue, while moving it from one side to the other. As the section apparatus is attached to the slider, it causes it to move in the plane which it describes, and allows it to move freely between the friction rollers in the projection rod. The slider thus describes the outline of a surface, or makes a section of the statue, while the etching point at the other end of the projection rod describes a perspective projection of the same on a prepared plate fixed on the drawing board. The operator then lowers the section apparatus one division, and proceeds as before; thus alternately lowering one division and describing a line, until the whole of the statue has been carefully passed over.

See *Report of Committee of the Society of Arts, on the Mode of Preventing the Forgery of Bank Notes*, 8vo, Lond., 1819; *Edinburgh Philosophical Journal*, vol. iii., p. 140.

The method of engraving on copper, in which the lines or strokes, instead of being cut with a tool or graver, are eaten in with aquafortis, is styled ETCHING. It is of later invention than engraving with the tool, of which it was at first only an imitation, practised by painters and other artists, as offering greater facilities of working than the graver. But being considered at first as a counterfeit kind of engraving, and inferior to the other, it was little cultivated; the closeness of the resemblance of the work to that performed by the graver being made the test of its merit, and the principal aim in those who pursued it. This restriction of the art of etching to the imitation of engraving greatly retarded its advancement, and many of the most able masters cramped their talents by the observance of so narrow a rule. This may be seen in the instances of Sadelers, Swaneberg, Villamena, and particularly Le Bosse, who, in his treatise on engraving, has laid it down as a principle, that the perfection of this kind consists in the close similitude of the work to that executed with the tool. But this absurd prepossession is now removed; and the method of working with aquafortis has been so far improved, that instead of being now deemed a spurious kind of engraving, it evidently appears, in many modern works, the foundation of an excellence that could never have been produced without it; since, though the neatness and uniformity of the hatchings which attend the use of the graver is more advantageous with respect to portraits, yet the liberty and facility of etching gives great opportunity to exercise the force of genius and fancy in historical engraving, where the effect of the whole, and not the minute exactness in finishing all the parts, constitutes the principal value.

There are two methods practised of engraving in this way; the one with a hard varnish or ground, and the other with a soft. The hard varnish was at one time much used, being better accommodated to the intention of imitating the engraving with the tool; as the firmness of the body of the varnish gave more opportunity of retouching the lines, or enlarging them with the oval-pointed needles, called by the French *echoppes*, as was practised by Le Bosse and others for that purpose. The soft varnish has now almost wholly superseded the use of the other, by the free working it admits of; which affords a power of expression incompatible with the greater inflexibility of the hard varnish, that confines the lines and hatches to such a regularity and sameness, as give stiffness of manner and coldness of effect to the work.

The combination of the use of scratching tools and aquafortis, which are now both employed in many cases, has given to etching that perfection it at present possesses. The truth and spirit of the outline which the method of working with aquafortis affords, and the variety of shades which the different kinds of black produce in this way, as well as other means of expressing the peculiar appearance and character of particular subjects, furnish what was defective in the sole use of the tool; whilst, on the other hand, the exactness and regularity of the lines, which are required for finishing many kinds of designs, are supplied by the tools; and by a judicious application of both, that complete finishing is obtained which either of them alone must necessarily want.

The manner by which this is performed, is by covering the surface of the plate with a proper varnish, or *ground*, as it is called, which is capable of resisting aquafortis, and then scoring or scratching away, by instruments resembling needles, the parts of this varnish or ground, in the places where the strokes or hatchings of the engraving are intended to be; then, the plate being covered with aquafortis, the scored and scratched parts (which are exposed by the removal of the ground or varnish) are corroded or eaten away, whilst the remaining portion of the plate, being secured and defended from the action of the acid, is untouched.

There are two methods of etching, as has been already observed, the difference of which consists as well in the kind of the varnish or ground as in that of the aquafortis adapted to each kind; but the general methods of performing them are alike in both cases. These varnishes or grounds are distinguished by the names of *hard* or *soft;* for in their consistence, or the resistance which they give to the needles, lies their essential variation from each other. The hard varnish, it is with good reason conjectured, was not the first in use, but soon took the place of the other, and was for some time the most received in practice, on account of its admitting the work to be made more like that of the graver; the soft has since, however, in its turn prevailed, to the exclusion in some degree of the hard, except in the case of particular subjects, but not so entirely as to take away the expediency of showing how it is performed. The manner of etching with the soft varnish is now, however, one of the most important objects of the art of engraving; and it is at present in universal use, sometimes alone, but more frequently intermixed with the work of the tool, and in some cases with great advantage, even where the whole is intended to pass for being performed by the graver.

Preparation of the soft varnish, according to Mr Lawrence, an eminent English engraver at Paris.—"Take of virgin wax and asphaltum each two ounces, of black pitch and Burgundy pitch each half an ounce. Melt the wax and pitch in a new earthenware glazed pot, and add to them, by degrees, the asphaltum, finely powdered. Let the whole boil till such time as that, taking a drop upon a plate, it will break when it is cold, on bending it double two or three times betwixt the fingers. The varnish, being then enough boiled, must be taken off the fire, and, letting it cool a little, must be poured into warm water, that it may work the more easily with the hands, so as to be formed into balls, which must be rolled up, and put into a piece of taffety for use."

It must be observed, first, that the fire be not too violent, for fear of burning the ingredients, a slight simmer-

ing being sufficient; secondly, that whilst the asphaltum is putting in, and even after it is mixed with them, the ingredients should be stirred continually with the spatula; and, thirdly, that the water into which this composition is thrown should be nearly of the same degree of warmth with it, in order to prevent a kind of cracking that happens when the water is too cold.

The varnish ought always to be harder in summer than in winter; and it will become so if it be suffered to boil longer, or if a greater proportion of the asphaltum or brown resin be used. The experiment above mentioned, of the drop suffered to cool, will determine the degree of hardness or softness that may be suitable to the season when it is used.

Preparation of the hard varnish used by Callot, commonly called the Florence Varnish.—Take four ounces of fat oil, very clear, and made of good linseed oil, like that used by painters; heat it in a clean pot of glazed earthenware, and afterwards put to it four ounces of mastich well powdered, and stir the mixture briskly till the whole be well melted; then pass the whole mass through a piece of fine linen into a glass bottle with a long neck, that can be stopped very securely; and keep it for the use that will be below explained.

Method of applying the soft varnish to the plate, and of blackening it.—The plate being well polished and burnished, as also cleansed from all greasiness by chalk or Spanish white, fix a hand-vice on the edge of the plate where no work is intended to be, to serve as a handle for managing it when warm; then put it upon a chafing-dish, in which there is a moderate fire, and cover the whole plate equally with a thin coat of the varnish; and whilst the plate is warm, and the varnish upon it in a fluid state, beat every part of the varnish gently with a small ball or dauber made of cotton tied up in taffety; which operation smoothes and distributes the varnish equally over the plate.

When the plate is thus uniformly and thinly covered with the varnish, it must be blackened by a piece of flambeau, or of a large candle which affords a copious smoke; sometimes two or even four such candles are used together, for the sake of despatch, that the varnish may not grow cold; which if it does during the operation, the plate must then be heated again, that it may be in a melted state when that operation is performed; but great care must be taken not to burn it, which, when it happens, may be easily perceived by the varnish appearing burnt and losing its gloss. The following expedient is made use of for the more commodiously blackening the varnish, and is particularly necessary where the plates are large: Fix a strong hook in the roof of the room, through which pass four pieces of cord of equal length, at the end of which are fixed four iron rings of about four inches in diameter, for supporting the corners of the plate. The plate, being thus suspended in the air, with the varnished side downwards, may be blackened with great convenience; but this is not, however, absolutely requisite, excepting in the case of large plates, which could not, without difficulty, be suspended, unless this or some other such contrivance were made use of.

It is proper to be very cautious in keeping the flambeau or candle at a due distance from the plate, lest the wick should touch the varnish, which would both sully and mark t. If it appear that the smoke has not penetrated the varnish, the plate must again be placed for some little time over the chafing-dish; and it will be found that, in proportion as the plate grows hot, the varnish will melt and incorporate with the black which lay above it, in such a manner that the whole will be equally pervaded by it.

Above all things, in this operation, the greatest caution should be used to keep the fire all the time moderate; and to move frequently the plate, and change the place of all the parts of it, that the varnish may be alike melted everywhere, and kept from burning. Care must also be taken, that during this time, and even till the varnish be entirely cold, no filth, sparks, or dust, fly on it; for they would then stick fast and spoil the work.

Method of applying the hard varnish.—This is precisely the same as that for the soft; it is spread equally over the warm plate with the taffety-ball, and smoked in the same manner; only, after it is smoked, it must be baked, or dried over a gentle fire of charcoal, till the smoke from the varnish begins to decrease; taking care not to overheat the plate, which would both soften it and burn the varnish.

The plate being thus prepared, and an exact drawing of the outlines of the design made upon thin paper, the other side of the paper must be well rubbed with chalk or Spanish whitening, or, which is better, with red chalk scraped to a powder: the loose chalk is then cleared off with a linen rag, and the stained side of the paper is laid upon the varnish, fixing the corners to the plate with wax or wafers, to prevent its shuffling; and with a blunted needle or pointer the drawing is slightly traced, and communicates to the varnish an exact outline of the design to be etched.

A variety of pointers is necessary for the work. Those used for the broad large strokes ought to be very blunt, exceedingly round, and well polished at the point; the sole of a shoe answers very well for polishing the points. The finest ought to be as sharp as a needle. If any scratches or false strokes happen in the working, they are to be stopped up with a hair pencil dipped in Venetian varnish mixed with lamp black, by which means these places will be defended from the action of the aquafortis.

The next operation is that of eating or corroding the plate with aquafortis, in order to which a border of soft wax, being a composition of bees-wax melted and tempered with a little Venice turpentine and tallow, must be fastened round the plate about an inch high, in the form of a little wall or rampart, to contain the aquafortis. At one of the corners of this border a gutter is usually made, which serves for commodiously pouring the aquafortis off the plate. The plate being thus bordered, take a due quantity of the refiner's aquafortis, mix it with half its quantity of common water, and pour it gently on, till it rise a finger's breadth above the surface of the plate; then, if all things have been rightly conducted, it will soon be seen that the aquafortis exerts its action in the hatchings which have been strongly touched; but those more weakly engraved will appear at first clear, and of the colour of the copper. The menstruum must therefore be suffered to continue on the plate till its effects become visible on the more tender parts; then the aquafortis should be poured off, the plate washed with clean water, and dried before the fire; after which take a small pencil dipped into the Venetian varnish, and cover with it the lighter parts of the plate. This being done, the aquafortis must again be poured on, and suffered to continue a longer or a shorter time, according to the strength of the menstruum or the nature of the engraving; after which it must be poured off as before, and the plate immediately washed with water.

It may be observed that, when the aquafortis is on the plate, a feather should be used to cleanse away the foulness of the verdigris that gathers in the hatchings by the operation of the aquafortis, and to give it more room to exert its action; for by moving the aquafortis to and fro on the plate by the feather, and brushing away the black saline matter where it appears to be formed, the hatchings will be cleansed and the aquafortis exert its whole force equally on every part.

The plate being thus sufficiently corroded by the aquafortis, and well washed with water, it must be warmed at the fire, and the border of wax removed; after which it must be made hotter till the varnish melt; then it must be well wiped with a linen cloth, and afterwards rubbed well with oil of olives, when it will be ready to be retouched and finished by the graver.

Etching *on Steel* is performed in the same manner as on copper. Of late years steel has generally been preferred to copper for this purpose, as, owing to its superior hardness, a much greater number of perfect impressions can be taken from the plate.

Etching *on Glass* is performed in the same manner, by first laying on a ground of bees' wax; then drawing on this surface with the needle, as in etching on copper; then pour on it sulphuric acid and flour spar, or fluoric acid sprinkled on it. After remaining on the glass for four or five hours, it may be taken off, and the work cleaned with oil of turpentine.

Engraving *on Precious Stones* is the representing of figures or devices, in relief, or indented, on various kinds of hard polished stones.

This art is at least as ancient as the time of Moses. From the Book of Exodus (xxviii. 9) we learn that he was commanded to take two onyx stones and engrave on them the names of the children of Israel, according to their birth, with the work of an engraver on stone, like the engravings of a signet. From this passage we may conclude that the Israelites had acquired a knowledge of the practice of gem and seal engraving, as well as of other arts, during their captivity in Egypt.

In the Book of Exodus (xxxv. 32) we learn that Bezaleel, the son of Uri, "had knowledge in all manner of workmanship, to devise curious works in gold, and in silver, and in brass, and in the cutting of stones to set them; and with him was Ahobab, an engraver and a cunning workman."

The art of engraving on precious stones is one of those in which the ancients excelled; there being various antique agates, cornelians, and onyxes, which surpass anything of the kind which the moderns have produced. Pyrgoteles among the Greeks, and Dioscorides under the first emperors of Rome, are the most eminent engravers we read of. The former was so esteemed by Alexander, that he forbade anybody else to engrave his head; and Augustus's head, engraven by the latter, was deemed so beautiful that the succeeding emperors chose it for their seal. The extravagant passion of the Roman matrons for engraved gems was satirized by Juvenal, and Pliny remarks that they "loaded their fingers with princely fortunes;" but these costly ornaments were not limited to the person;—this extravagance gradually extended to the wearing apparel of both sexes, and to other articles, and the dress of the wealthy Romans sometimes absolutely glittered with engraved gems.

All the polite arts having been buried under the ruins of the Roman empire, that of engraving on stones met with the same fate. It was retrieved in Italy at the beginning of the fifteenth century, when one John of Florence, and after him Dominic of Milan, performed works of this kind no way to be despised. From that time sculptures of this kind became common enough in Europe, and particularly in Germany, whence great numbers were sent into other countries; but they fell far short of the beauty of those of the ancients, especially those executed on precious stones; for, as to those on crystal, the Germans, and after them the French, &c., have succeeded well enough.

In this branch of engraving artists make use either of the diamond or of emery.

The diamond, which is the hardest of all stones, is only cut by itself, or with its own matter. The first thing to be done in this branch of engraving is, to cement two rough diamonds to the ends of two sticks large enough to hold them steady in the hand, and to rub or grind them against each other till they be brought to the form desired. The dust or powder which is rubbed off serves afterwards to polish them; and this is performed with a kind of mill that turns a wheel of soft iron. The diamond is fixed in a brass dish, and, being thus applied to the wheel, it is covered with diamond dust, mixed with oil of olives; and when the diamond is to be cut facet-wise, first one face, and then another, is applied to the wheel. Rubies, sapphires, and topazes, are cut and formed in the same way on a copper wheel, and polished with tripoli diluted in water. As to agates, amethysts, emeralds, hyacinths, garnets, rubies, and others of the softer stones, they are cut on a leaden wheel, moistened with emery and water, and polished with tripoli on a pewter wheel. Lapis-lazuli, opal, and some others, are polished on a wooden wheel. To fashion and engrave vases of agate, crystal, lapis-lazuli, or the like, a kind of lathe, like that used by pewterers, is made use of to hold the vessels, which are to be wrought with proper tools. That of the engraver generally holds the tools, which are turned by a wheel; and the vessel is held to them to be cut and engraved, either in relief or otherwise—the tools being moistened from time to time with diamond dust and oil, or at least emery and water. To engrave figures or devices on any of these stones when polished, such as medals, seals, and the like, a little iron wheel is used, the ends of whose axis are received within two pieces of iron, placed upright, as in the turner's lathe, and so adjusted as to be brought closer, or set further apart, at pleasure. At one end of the axis are fitted the proper tools, which are kept tight by a screw. Lastly, the wheel is turned by the foot, and the stone applied by the hand to the tool.

The tools are generally of iron, and sometimes of brass. They vary in form, but generally bear some resemblance to chisels, gouges, and the like. Some have small round heads like buttons; others are like ferrels, to take the pieces out; and others again are flat. When the stone has been engraved, it is polished on a hair brush-wheel with tripoli.

For engraving on stone, see Lithography. (w. h. l.)

ENGOULEE, in *Heraldry*, a term applied to crosses, saltires, &c., when their extremities enter the mouths of beasts, as lions, leopards, &c.

ENGRAINED, in *Dyeing*, dyed in the raw material.

ENGUERA, a town of Spain, province of Valencia, and 32 miles S.S.W. of the town of that name. Pop. 5244.

ENHARMONIC. See Music, §§ *Harmony* and *Modulation.*

ENIGMA. See Ænigma.

ENIPEUS, now the Fersaliti, a river of Thessaly, rising in Mount Othrys, and which, after uniting its waters with those of the Apidanus, falls into the Peneus. There is also a small river of this name in Macedonia, and another in Elis.

ENKHUYZEN, a fortified town of Holland, province of North Holland, on the Zuyder Zee, 28 miles N.N.E. of Amsterdam. The harbour, which was formerly very commodious, is now, from the accumulation of sand, all but useless. It has, however, extensive herring fisheries, and some trade in cheese, fish, salt, timber, &c. Pop. 6000.

ENLISTMENT, in British naval and military affairs, denotes a voluntary engagement to serve as a private soldier or sailor. The term of service in the army may be either indefinite, as during the continuance of a war, or for a fixed period; which period varies in the different classes of troops. In the infantry, this period cannot exceed ten years; in the cavalry, artillery, or other ordnance corps, twelve years; and in the East India Company's service it may be either indefinite, or for twelve years. In each case, if the recruit be under eighteen years of age, his term of service is to be reckoned from the day of his attaining that age. The term of enlistment in the marine forces is limited to twelve years. (See acts 10th and 11th Vict., cap. 39.)

In the British navy, according to an act passed in 1835, a man is allowed to enlist for a period not exceeding five

years; and on the expiration of that term he is entitled to his discharge, under certain restrictions, if he should desire to quit the service.

ENMANCHE (Fr. *manche, a sleeve*), in *Heraldry*, an epithet used when lines are drawn from the centre of the upper edge of the chief to the sides, to about half the breadth of the chief, as if it had sleeves upon it.

ENNEAGON, in *Geometry*, a polygon with nine sides.

ENNEATICAL (ἐννέα, *nine*), relating to the ninth of anything; as the enneatical days (or every ninth day) of a disease.

ENNIS, a municipal and parliamentary borough and market-town of Ireland, capital of the county of Clare, situated on the Fergus, here crossed by 4 bridges. Distance from Limerick, 20 miles W.N.W. The town is meanly and irregularly built. The principal edifices are the parish church, a Roman Catholic chapel, used as the cathedral for the diocese of Killaloe, a Methodist meeting-house, an endowed and two national schools, county court-house, fever hospital, infirmary, gaol, workhouse, and market-house. At a short distance from the town is Ennis College, founded by Erasmus Smith. Ennis has a considerable trade in grain, flour, and other commodities, which are conveyed in lighters for shipment to Clare, 3 miles lower down the river. There are extensive flour mills in the town. Market-day, Saturday. Races are held annually in the neighbourhood. A railway is in course of construction between this town and Limerick. Ennis returns a member to parliament. Electors (1851) 143. Pop. (1851), in town 7800; in workhouse 3542; gaol 727; infirmary 96.

ENNISCORTHY, a market-town of Ireland, county of Wexford, and 13 miles N.N.W. of the town of that name. The town, which is situated on the declivities of steep hills, on both sides of the river Slaney, is well built and thriving. The chief public buildings are the parish church, Roman Catholic chapel, convent, Methodist and Quaker meeting-houses, court-house, market-house, hospital, bridewell, and an old castle. It is a place of considerable trade; and two extensive quays have been constructed along the river. There are tanneries, breweries, flour-mills, a distillery, rope-walk, and an earthenware manufactory. Market-days, Thursday and Saturday. Pop. (1851) 7735. In the vicinity of the town is Vinegar Hill.

ENNISKILLEN, a municipal and parliamentary borough and market-town of Ireland, capital of the county of Fermanagh. It is situated on an island in the strait or river which connects the upper and lower lakes of Lough Erne, 102 miles N.W. from Dublin. The town occupies the whole island, and is connected with two suburbs on the mainland on each side by two bridges. The chief public buildings are the parish church, a Roman Catholic chapel, Presbyterian and Methodist meeting-houses, county court-house, prison, infirmary, town-hall, Royal School founded by Charles I. and richly endowed, three national schools, union workhouse, and three barracks. It has also a brewery, two tanneries, and a small manufactory of cutlery; and a considerable trade in cattle, timber, coal, provisions, and linen. Market-days, Tuesday and Thursday. Enniskillen distinguished itself during the war of 1689 by its attachment to the liberal side, and by its resisting and defeating a superior force sent against it by James II. Part of the brave defenders of the town were subsequently formed into a regiment of cavalry, which still retains the name of the Enniskillen Dragoons. Pop. (1851) 5998. It returns a member to parliament. Registered electors (1851) 172.

ENNISTYMON, a market-town of Ireland, county of Clare, on a small river of the same name, near its mouth in Liscanor bay, 14 miles W. by N. of Ennis. Pop. (1851) 1729, exclusive of 1070 in workhouse and 12 in bridewell.

ENNIUS, Q., a celebrated Roman poet, born at Rudiæ in Calabria, B.C. 239. Of his early life nothing is known, save a tradition that he entered the Roman army and rose to the rank of centurion. In the thirty-eighth year of his age he went to Rome under the protection of Cato; but he left it shortly afterwards, and served in the Greek campaigns under M. Fulvius Nobilior. Through the son of this commander, Ennius, when far advanced in years, obtained the rights of citizenship, at that time the greatest honour for which an alien could look in the Roman commonwealth. During the wars with Greece he made himself thoroughly master of the language and literature of that country; and on his return to Rome he formed the bold design of modelling the Latin language on the basis of the Greek, especially in so far as the metres of the latter tongue were capable of being adapted to the genius of the former. The success with which he worked out this idea, and his general reputation as a man of learning (for he spoke no fewer than three different languages—a very rare accomplishment in those days), gained for him the respect even of the haughtiest patrician families whose children he instructed. With the Scipios, in particular, he lived on terms of the greatest intimacy; and when at length he died in the seventieth year of his age (B.C. 169), he was buried in the tomb of that illustrious family.

The works of Ennius have long since perished; though at what date cannot be exactly determined. A. G. Cramer believes them to have existed entire so late as the thirteenth century, though there are good reasons for doubting the correctness of this statement. Such portions of his works as are quoted by Cicero and other ancient writers, though they amount in all to some hundreds of lines, are yet so fragmentary and unconnected that it is impossible to form from them any estimate of the works from which they are extracted. Some few of these quotations are in themselves complete and perfect pictures, often of much originality and force, such as that preserved by Aulus Gellius, in which the duties of a client to a patron are set forth. Though we cannot now judge for ourselves of Ennius's merits as a poet, yet if the testimony of the most competent judge among his own countrymen be believed, he possessed no mean claims to the title of the Roman Homer. As in the case of the Grecian bard, there arose a race of men who earned a livelihood by reciting his martial strains to the rural population in the Roman provinces, and even to the more refined audiences of the metropolis. It is no mean attestation to the genuine worth of Ennius's lays that they suited the tastes of every grade of Roman society, and retained their popularity unimpaired till the days of the empire. Cicero more than once speaks of Ennius as the greatest of Roman poets; and Virgil not only praised him, but borrowed from him some of the finest thoughts which adorn the *Æneid*.

The service which Ennius rendered to the Latin as a national tongue we have already alluded to. The benefits which he conferred upon it are analogous both in kind and in degree to those which Chaucer conferred upon the English tongue. Before his time the Romans could hardly be said to possess a regularly constructed language, or any literature beyond the rude ballads which they received by oral tradition from their ancestors. He left them both a language and the basis of an independent and national literature.

In the fragments of his works which have survived to our day we observe traces of the most intense nationality. They all breathe a high spirit of independence, and display loftiness and vigour of thought, and an energy of expression such as none of the later poets of Rome ever attained, and which amply compensate the trouble of mastering the archaic forms in which he delighted. The reader who will not allow himself to be repelled by the apparent clumsiness or even coarseness of this antique phraseology, will probably admit that after all they are better adapted for expressing that style of thought which Ennius cultivated than the more refined dialect of a later era.

The most important of his works was his *Annalium Libri XVIII.*; an epic poem in which was related the history of Rome, with all its mythological and fabulous incrustations, from the era of Mars and Rhea till the end of the second Punic war. Next in importance were his plays, which were for the most part translated or adapted from the Greek, the original metres being preserved. Of his tragedies, the titles and fragments of twenty-six have been preserved. Similar remains of four comedies have come down to us. His satires, which may rank third in importance, were written in four or six books, and in a great variety of metres. His other works are very miscellaneous in their character. These are—*Scipio*, a panegyric upon the elder Africanus; *Epicharmus*, a didactic poem, which, from some fragments which have descended to us, may be conjectured to have borne a strong resemblance to Lucretius's great work; *Phagetica*, a treatise upon edible fishes, believed to be a translation from Archestratus; *Epigrams*, of which only two upon Scipio now remain; *Protreptica*, a work on practical ethics, but whether prose or poetical, cannot now be decided. The first edition of the poetical fragments of Ennius appeared at Paris in 1564, from the press of the Stephenses; but a much more complete and correct edition appeared at Naples about the close of the same century, under the care of Jerome Colonna, which was reprinted with the notes of Voss and Delrio at Amsterdam in 1707. This must still be regarded as the best edition of Ennius.

ENOCH, one of the antediluvian patriarchs, son of Jared, and father of Methuselah. After a life of 365 years spent in walking with God, he was miraculously translated into heaven. The apocryphal book bearing his name was composed originally in Chaldee or Hebrew, but both the original version and the Greek translation seem now irrecoverably lost. The loss of these has been partly supplied by the Ethiopic version, which Bruce brought home with him from Abyssinia, and which was translated into English by Dr Lawrence in 1821. From the chronological notes to be found in the book itself, Dr Davidson supposes it to have been written probably about B.C. 40: and, on this supposition, it throws considerable light on the Christology of the age preceding our Saviour's advent. Lücke and Stuart, however, suppose it to have been written by a Jew already instructed in Christianity. The language ascribed to Enoch in the Epistle of Jude, is to be found, with some variation, in this work.

ENOS, the ancient *Ænos*, a seaport-town of European Turkey, province of Rumili, sanjiac of Gallipoli, and 38 miles N.W. of the town of that name. It is situated on the S. side of the gulph of Enos, near the mouth of the Maritza, and is in fact the seaport of Adrianople. Its position is admirably adapted for trade; but a sandbank has been allowed to form at the mouth of the harbour, so that none but vessels of the smallest size can now enter, all others being obliged to load and unload outside the bank. Pop. of town about 7000. The gulf of Enos is 14 miles in length, by 5 in breadth.

ENS (from *esse, to be*), in *Metaphysics*, entity, being, existence. This the schoolmen call *ens reale* and *ens positivum*, to distinguish it from their *ens rationis*, which exists but in the imagination.

ENS, a town in the Austrian province of the Upper Ens, situated on a steep bank, near the junction of the Ens with the Danube, 10 miles S.E. of Linz. It is surrounded by old walls, and has some manufactures of iron and steel. Pop. 3500. Ens was the headquarters of Napoleon in 1809.

ENS, or ENNS, a river of Austria, falling into the Danube. It forms the boundary between the two provinces of the Lower and Upper Ens, commonly called Lower and Upper Austria, and constituting the Archduchy of Austria. See AUSTRIA.

ENSEELED, in *Falconry*, is said of a hawk that has her eyes closed by a thread drawn through her upper eye-lid and made fast under the beak.

ENSHAM, a village, formerly a market-town of England, county of Oxford, on the Isis, 64 miles from London. It has two handsome stone bridges over the Isis, a fine Gothic church, a singular and very ancient tapering cross, and remains of an extensive abbey. Pop. of parish (1851) 1941.

ENSIGN, in the military art, a flag or banner under which soldiers are ranged according to the different companies or parties to which they belong.

The Turkish ensigns are horses' tails; those of the European nations generally are made of silk, and ornamented with divers figures, colours, arms, and devices. We learn from Xenophon that the ensign borne by the Persians was a golden eagle on a white ground: the Corinthian standard was the winged horse or Pegasus: the Athenians adopted the owl: the Messenians the Greek letter M: the Lacedæmonians the A. The Romans, at different times, had various ensigns, as the wolf, minotaur, horse, and boar; till at length they assumed the eagle, in the second year of the consulate of Marius. A military ensign on a medal of a Roman colony indicates a colony peopled with veterans.

ENSIGN is also the designation of the officer who carries the colours. He is the lowest commissioned officer in a company of infantry. See COMMISSION, *Military*.

Naval ENSIGN, a large standard or banner hoisted over the poop of a ship on a long pole called the *ensign staff*. It is used to distinguish ships of different nations, or to characterize the different squadrons of the same navy. The British ensign in ships of war is known by a double cross, viz. that of St George and St Andrew, formed upon a field which is either red, white, or blue.

ENT, SIR GEORGE (1604–1689), an English physician, born at Sandwich in Kent. He received his medical degree at Padua; was afterwards president of the college of physicians in London; and received the honour of knighthood from Charles II. His principal work is a defence of his friend Harvey, entitled *Apologia pro Circulatione Sanguinis, contra Æmilium Parisanum.*

ENTABLATURE, in *Architecture*, that part of an order which rests upon the abaci of the columns. It is composed of the architrave, the frieze, and the cornice. See ARCHITECTURE, Plate LXII. fig. 1.

ENTAIL, an arrangement for adjusting or limiting the succession to landed property in a line of succession predetermined by the entailer. The term, though it is of frequent use in the legislature and the courts of justice, is rather colloquial than technical, being applicable in England and Ireland to the form of estate technically called a *Fee Tail*, and in Scotland to the destination technically called a *tailzie*. The word is of doubtful origin: some would derive it from the Latin *talis*, as being an indication of certain persons who are to succeed; but the most commonly received derivation is from the same root with the French *tailler*, to cut; and Spelman tells us, that a fee is called *talliatum* when certain faculties are cut away from it so that it can pass to no heirs save those springing from a particular body. Under the head of the Law of Entail it has been customary to treat the policy of restraints on the right to possess and dispose of landed property, in connection with history, politics, and political economy; and though the intricacies and niceties which have been adopted to carry out particular destinations, or to defeat them, are of considerable importance in the science of conveyancing, it is in connection with the policy of restraining or freeing the commerce in land that the subject of entails is chiefly interesting.

There has been a remarkable difference in the history of the entail system in England and Scotland, connected with the differing political progress of the two countries. It is said that from very early times the judges administering the common law in England were accustomed to aid in stripping

destinations of land of their conditions and limitations, by giving effect to fictitious sales by tenants in possession and reconveyances into their hands, which endowed them with fee-simple or unlimited ownership. The passing of the statute of Westminster, in 1285, is generally supposed to have been a remedy sought by the aristocracy against those practices of the common lawyers which they deemed an infringement of their territorial power. This statute is peculiar and argumentative in its phraseology, complaining that in certain enumerated cases "feofees had power to alien the land so given, and to disherit the issue of the land contrary to the minds of the givers, and contrary to the form expressed in the gift;" and it enacts, "that the will of the giver, according to the form in the deed of gift manifestly expressed, shall be from henceforth observed." Blackstone tells us, that during about two centuries when this statute was observed,—"Children grew disobedient when they knew they could not be set aside; farmers were evicted of their leases made by tenants in tail; for if such leases had been valid, then under colour of long leases the issue might have been virtually disinherited; creditors were defrauded of their debts; for if tenant in tail could have charged his estate with their payment, he might have also defeated his issue by mortgaging it for as much as it was worth; innumerable latent entails were produced to deprive purchasers of the lands they had fairly bought—of suits in consequence of which our ancient books are full; and treasons were encouraged—as estates-tail were not liable to forfeiture longer than for the tenant's life." (B. ii. chap. vii.) It is said to have been owing to the encouragement which, for this last reason, King Edward III. extended to a judicial remedy, that the judges in the celebrated case of Taltarum gave countenance to a new fiction for checking the course of entails. When it was brought into form, it was known by the name of *common recovery*. This was a judgment in a fictitious suit, in which the tenant of the estate was made defendant. In its simpler form the tenant or possessor appeared to the action, and called upon a fictitious person to vouch or warrant his title. That person's default was the break which judicially stopped the course of the entail, and other proceedings more or less complex, according to circumstances, restored the estate in fee-simple to the tenant. The form became a systematic but complex department of English conveyancing, until it was simplified in 1832, by the passing of the 3d and 4th Will. IV., c. 74, which substituted a deed enrolled for the fictitious process. A subsequent act, passed in 1838, facilitated the realization of entailed estates for the benefit of creditors. In Scotland, the history of the entail system is so far different, that it was there created and strengthened by the ingenuity of lawyers, who, as fast as their brethren discovered assailable points in the usual form of the deed, fortified it with new clauses. The simplest form of the deed was a mere nomination of a certain series of heirs, or direction to invest them,—this was easily defeated, and the "prohibitory clause" was inserted to prohibit the heir in possession from altering the destination. Still when he did alter it, it was but a precept disobeyed, and did not change the condition of the property; hence the claues "irritant" was introduced, by which the contravener forfeited his title. There was still a deficiency—the forfeiture might be incurred, yet no one had a right to come forward and enforce it by claiming the estate forfeited, and the form was completed by the introduction of the clause "resolutive," which devolved the forfeited estate on a claimant who might prosecute on the forfeiture as the true owner. Sir Thomas Hope, a lawyer famous in the religious disputes of the seventeenth century, has the reputation of being the inventor of these clauses, which were sanctioned in the year 1685, by a statute which reduced entails in Scotland to a systematic form. An entail scientifically and accurately constructed, not only deprived the heir in possession of all power to alter the line of succession, but protected the estate from his creditors, and transmitted it untouched to the next in succession. It precluded provision to widows and children; but measures were adopted for partially remedying this part of the evil effects.

During the eighteenth, and nearly the half of the nineteenth century, the practice of entailing crept like some great blighting disease over the soil of Scotland, not only perpetrating gross injustice to creditors, and creating great personal hardships by condemning to destitution the children of parents enjoying large estates, but checking the progress of agriculture, and interrupting the commerce in land. The practice of the law made a curious and faint protest against the progress of the system, by requiring that the terms of an entail were to be held *strictissimi juris;* that is, that the meaning of the clauses should never be sought for, or be explainable by even the simplest and most obvious process of interpretation, but that any defect, such for instance as a clerical error in the deed or the record by the omission of a word, should vitiate the entail.

The effects of the system were felt as sufficiently alarming by the public at large; but the great patrimonial interests involved in existing entails seemed to unite in their defence a body too formidable to be assailed, while the tract of country already subject to the influence of the restraints was so large as to render any remedy which was not capable of disentangling existing restrictions comparatively ineffective. In 1847, when the evil had reached its climax, the legal administration in Scotland was fortunately in the hands of Andrew Rutherfurd, then Lord Advocate, a man of very signal attainments, and among the greatest British lawyers —certainly the greatest Scottish lawyer of his age. Being engaged in a general plan for the simplification of the tenure and transference of landed property (see CONVEYANCING), he undertook the arduous task of an equitable adjustment of the entail question. The main objects were the protection of all interests founded on just expectations—a freedom to dispose of such well-founded interests at the option of the owners, for the purpose of disentangling property of the restraints of an entail, and general freedom to the holders under future entails to convert their limited holdings into property. For this object, the first of August 1848 was made the turning point. Persons then in existence, and holding under entails of prior date, were enabled to disentail them only by certain intimations and equitable consents. Persons unborn at that date had greater facilities, and entails made after the assigned date were placed at the virtual disposal of the heir in possession when of full age. The number of advertisements containing the statutory notices of disentails which followed this measure gave ample evidence of its success; and there is no doubt that it will greatly increase the productive value of land in Scotland, and promote the general prosperity of the country. (J. H. B.)
